- hepatomegaly (70%) → may get portal hypertension
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

**Investigations**
- CBC: anemia, variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease), increased LDH (2° to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased B12 (2° to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets and megakaryocyte fragments
- JAK2 PCR
- bone marrow aspirate: “dry tap” in as many as 50% of patients (no blood cells aspirated)
- bone marrow biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

**Treatment**
- allogeneic stem cell transplant is potentially curative
- symptomatic treatment:
  - transfusion for anemia
  - erythropoietin: 30-50% of patients respond
  - androgens (e.g. danazol has shown transient response with response rates of <30%)
  - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, systemic symptoms
  - α-interferon (as second line therapy)
  - splenectomy (as third line therapy; associated with high mortality and morbidity)
  - radiation therapy for symptomatic extramedullary hematopoiesis, symptomatic splenomegaly
  - thalidomide, JAK2 inhibitors, and etanercept may improve quality of life and spleen size, but not survival

**Prognosis**
- International Prognostic Scoring System (IPSS) for IMF uses 5 factors to determine mean survival:
  - presence of constitutional symptoms: age >65; hemoglobin <100 g/L; leukocyte count >25,000/mm³; circulating blast cells ≥1%
  - based on the calculated score, a patient’s IMF is categorized as “low”, “intermediate 1”, “intermediate 2”, or “high” with a mean survival of 135, 95, 48 and 27 mo respectively
  - risk of transformation to AML (8-10%)

**Essential Thrombocythemia (ET)**

**Definition**
- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocythemia
Epidemiology
- Increases with age; F:M = 2:1, but F=M at older age

Diagnosis (2008 WHO Criteria) requires meeting all four criteria:
1. Sustained platelet count >450 x 10^9/L
2. Bone marrow biopsy specimen showing proliferation mainly of the megakaryocytic lineage with increased number of enlarged, mature megakaryocytes. No significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
3. Not meeting WHO criteria for PV, primary myelofibrosis, BCR-ABL CML or myelodysplastic syndrome or other myeloid neoplasms
4. Demonstration of JAK2 V617F (or in its absence another clonal marker), no evidence for reactive thrombocytosis

Clinical Features
- Often asymptomatic
  - Vasomotor symptoms (40%)
    - Headache (common), dizziness, syncope
    - Erythromelalgia (burning pain of hands and feet, dusky colour, usually worse with heat, caused by platelet activation → microvascular thrombosis)
  - Thrombosis (arterial and venous)
  - Bleeding (often GI, associated with platelets >1000 x 10^9/L)
  - Constitutional symptoms, splenomegaly
  - Pregnancy complications; increased risk of spontaneous abortion
  - Risk of transformation to AML (0.6-5%), myelofibrosis

Investigations
- CBC: increased platelets; may have abnormal platelet aggregation studies
- JAK2 PCR assay
- Bone marrow hypercellularity, megakaryocytic hyperplasia, giant megakaryocytes
- Increased K+, increased PO43- (2o to release of platelet cytoplasmic contents)
- Diagnosis: exclude other myeloproliferative disorders and reactive thrombocytosis

Treatment
- Low dose ASA if previous history of thrombotic event, ≥1 cardiovascular risk factors, older or symptomatic
- Cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st line therapy), anagrelide, interferon-α, or 32P (age >80 or lifespan <10 yr)
- Splenectomy not recommended (increased risk of bleeding episodes, thrombosis)

Lymphoid Malignancies

Acute Lymphoblastic Leukemia (ALL)

Definition
- Malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic cells of the marrow
- WHO subdivides ALL into two types depending on cell of origin
  1. B-cell: precursor B lymphoblastic leukemia
  2. T-cell: precursor T lymphoblastic leukemia
- The French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged, as morphology is not prognostic

Clinical Features
- See Acute Myeloid Leukemia, H35 for full list of symptoms
- Distinguish ALL from AML based on Table 30
- Clinical symptoms usually secondary to:
  - Bone marrow failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), thrombocytopenia
  - Organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeal signs (headache, N/V, visual symptoms; especially in ALL relapse)

Investigations
- CBC: increased leukocytes >10 x 10^9/L (occurs in 50% of patients); neutropenia, anemia or thrombocytopenia
- May have increased uric acid, K+, PO43-, Ca2+, LDH
- PT, aPTT, fibrinogen, D-dimers for DIC
- Leukemic lymphoblasts lack specific morphological (no granules) or cytochemical features, therefore diagnosis depends on immunophenotyping
- Cytogenetics: Philadelphia (Ph) chromosome in ~25% of adult ALL cases
• CXR: patients with ALL may have a mediastinal mass
• LP prior to systemic chemotherapy to assess for CNS involvement (ensure adequate platelet count and PT/PTT)

**Treatment**

• eliminate abnormal cloned cells:
  1. **Induction:** to induce complete remission (undetectable leukemic blasts, restore normal hematopoiesis)
  2. **Consolidation and/or intensification chemotherapy**
     - consolidation: same chemotherapy to eliminate subclinical leukemic cells
     - intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
  3. **Maintenance chemotherapy:** low dose intermittent chemotherapy over prolonged period (2-3 yr) to prevent relapse
  4. **Prophylaxis:** CNS radiation therapy or methotrexate (intrathecal or systemic)
• hematopoietic stem cell transplantation: potentially curative (due to pre-implant myeloablative chemoradiation and post-implant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high

**Prognosis**

• depends on response to initial induction or if remission is achieved following relapse
• good prognostic factors: young, WBC <30 x 10^9/L, T-cell phenotype, absence of Ph chromosome, early attainment of complete remission
• achievement of first remission: 60-90% 
• childhood ALL: 80% long term remission (>5 yr)
  - higher cure rates in children because of better chemotherapy tolerance, lower prevalence of bcr-abl fusion gene (associated with chemotherapeutic resistance)
• adult ALL: 30-40% 5-yr survival

**Lymphomas**

**Definition**

• collection of lymphoid malignancies in which malignant lymphocytes accumulate at lymph nodes and lymphoid tissues
  - leading to lymphadenopathy, extranodal disease and constitutional symptoms

**Table 31. Ann Arbor System for Staging Lymphomas**

<td>Diffuse involvement of one or more extralymphatic organs including bone marrow</td>
</tr>
</tbody>
</table>

• subtypes:
  - A = absence of B-symptoms (see Approach to Lymphadenopathy, H11)
  - B = presence of B-symptoms

**Treatment of ALL vs. AML**

• No proven benefit of maintenance chemotherapy in AML
• No routine CNS prophylaxis in AML

**To Differentiate AML From ALL:** Remember Big and Small ALL

• Ann Arbor staging can be used for both Hodgkin and non-Hodgkin lymphoma, but grade/histology is more important for non-Hodgkin lymphoma because the outcome differs significantly depending on type of lymphoma.
• Prognostic scores are different for indolent versus aggressive lymphomas.
• Highly aggressive lymphomas act like acute leukemias.

**Hodgkin is distinguished from non-Hodgkin lymphoma by the presence of Reed-Sternberg cells.**

Hodgkin Lymphoma

Definition
• malignant proliferation of lymphoid cells with Reed-Sternberg cells (thought to arise from germinal centre B-cells)

Epidemiology
• bimodal distribution with peaks at 20 yr and >50 yr
• association with Epstein-Barr virus in up to 50% of cases, causal role not determined

Clinical Features
• asymptomatic lymphadenopathy (70%)
  ▪ non-tender, rubbery consistency
  ▪ cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
• splenomegaly (50%) ± hepatomegaly
• mediastinal mass
  ▪ found on routine CXR, may be symptomatic (cough)
  ▪ rarely may present with SVC syndrome, pleural effusion
• systemic symptoms
  ▪ B symptoms (especially in widespread disease; fever in 30%), pruritus
• non-specific/paraneoplastic
  ▪ alcohol-induced pain in nodes, nephrotic syndrome
• starts at a single site in lymphatic system (node), spreads first to adjacent nodes
  ▪ disease progresses in contiguity with lymphatic system

Investigations
• CBC
  ▪ anemia (chronic disease, rarely hemolytic), eosinophilia, leukocytosis, platelets normal or increased early, decreased in advanced disease
• biochemistry
  ▪ HIV serology
  ▪ LFTs (liver involvement)
  ▪ RFTs (prior to initiating chemotherapy)
  ▪ ALP, Ca++ (bone involvement)
  ▪ ESR, LDH (monitor disease progression)
• imaging
  ▪ CXR, CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement), gallium scan (assess treatment response)
  ▪ cardiac function assessment (MUGA or echocardiography): for patients at high risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, CVA), treatment can be cardiotoxic
  ▪ PFTs: if history of lung disease (COPD, smoking, previous radiation to lung)
• excisional lymph node biopsy confirms diagnosis
• bone marrow biopsy to assess marrow infiltration (only necessary if B-symptoms, stage III or IV, bulky disease or cytopenia)

Treatment
• stage I-II: chemotherapy (ABVD) followed by involved field radiotherapy (XRT)
• stage III-IV: chemotherapy (ABVD) with XRT for bulky disease
• relapse, resistant to therapy: high dose chemotherapy, bone marrow transplant
  ▪ new imaging modalities increasingly used including PET scans used to follow response to treatment

Complications of Treatment
• cardiac disease: secondary to XRT, adriamycin is also cardiotoxic
• pulmonary disease: secondary to bleomycin (interstitial pneumonitis)
• infertility: recommend sperm banking
• secondary malignancy in irradiated field
  ▪ <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
  ▪ solid tumours of lung, breast; >8 yr after treatment
• non-Hodgkin lymphoma
• hypothyroidism: post XRT

Common Chemotherapeutic Regimens

CHOP: cyclophosphamide, hydroxydoxorubicin (Adriamycin), vincristine (Oncovin), prednisone
VAD: vincristine, adriamycin, dexamethasone
ABVD: adriamycin, bleomycin, vinblastine, dacarbazine
BEACOPP: bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine and prednisone
**Prognosis**

- Hasenclever adverse prognostic factors:
  1. serum albumin <40 g/L (4 g/dL)
  2. hemoglobin <105 g/L (10.5 g/dL)
  3. male
  4. stage IV disease
  5. age ≥45 yr
  6. leukocytosis (WBC >1.5 x 10^9/L)
  7. lymphocytopenia (lymphocytes <0.06 x 10^9/L or <8% of WBC count or both)

- prognostic score
  - each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

**Non-Hodgkin Lymphoma (NHL)**

**Definition**

- malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

**Classification**

- multiple classification systems exist at present and may be used at different centres
- can originate from both B- (85%) and T- or NK- (15%) cells
  - B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt’s lymphoma, mantle cell lymphoma
  - T-cell NHL: e.g. mycosis fungoides, anaplastic large cell lymphoma
- WHO/REAL classification system: 3 categories of NHLs based on natural history
  - indolent (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL, mantle cell lymphoma
  - aggressive (~50% of NHL): e.g. diffuse large B-cell lymphoma
  - highly aggressive (~5% of NHL): e.g. Burkitt’s lymphoma

**Clinical Features**

- painless superficial lymphadenopathy, usually >1 lymph node region
- usually presents as widespread disease (exception is aggressive lymphoma)
- constitutional symptoms not as common as in Hodgkin lymphoma
- cytopenia: anemia ± neutropenia ± thrombocytopenia can occur when bone marrow is involved
- abdominal signs
  - hepatosplenomegaly
  - retroperitoneal and mesenteric involvement (2nd most common site of involvement)
- oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
- extranodal involvement: most commonly GI tract; also testes, bone, kidney
- CNS involvement in 1% (often with HIV)

**Investigations**

- CBC:
  - normocytic normochromic anemia
  - autoimmune hemolytic anemia
  - advanced disease: thrombocytopenia, neutropenia and leukoerythroblastic anemia
- peripheral blood film may show lymphoma cells
- flow cytometry of peripheral blood is valuable for low-grade NHL
- biochemistry:
  - increase in uric acid
  - abnormal LFTs in liver metastases
  - increased LDH (rapidly progressing disease, poor prognostic factor)
- CXR, CT neck, abdomen, pelvis for staging
- PET is useful for monitoring response to treatment and evaluation of residual tumour following therapy in aggressive histological disease
- diagnosed by:
  - lymph node biopsy: excisional biopsy preferred, FNA unreliable
  - bone marrow biopsy: not optimal for diagnosis as BM may not be involved

**Treatment**

- localized disease (e.g. GI, brain, bone, head and neck)
- radiotherapy to primary site and adjacent nodal areas
- adjuvant chemotherapy
- surgery: splenic marginal zone lymphoma
- **indolent lymphoma**: goal of treatment is symptom management
  - watchful waiting
  - radiation therapy for localized disease
  - CHOP + rituximab, an anti-CD20 antibody (CHOP-R) for advanced stage disease

FFP = freedom from progression at 5 yr.

**International Prognostic Factors**

- **Project 1998**
- **Prognostic Factors**
- **FFP**
- 0: 84%
- 1: 77%
- 2: 67%
- 3: 60%
- 4: 51%
- 5-7: 42%

**FFP = freedom from progression at 5 yr.**

**Non-Hodgkin Lymphoma (NHL): Associated Conditions**

- Immunodeficiency (e.g. HIV)
- Autoimmune diseases (e.g. SLE)
- Infections (e.g. EBV)

**NHL: Associated Conditions**

- Infections (e.g. EBV)
- Autoimmune diseases (e.g. SLE)
- Immunodeficiency (e.g. HIV)

**CHOP-like Chemotherapy with or without Rituximab in Young Patients with Good-Prognosis Diffuse Large B-Cell Lymphoma (MInT)**

- **Lancet Oncol** 2011;12:1013-1022
- **Study**: International RCT with a median follow-up of 72 mo.
- **Participants**: 824 patients with good-prognosis diffuse large B-cell lymphoma who had ≤1 risk factor, stage I/IV disease or stage I disease with bulk (age: 18 to 60 yr).
- **Intervention**: Patients received either 6 cycles of CHOP-like chemotherapy and rituximab (CCR; n=413) or 6 cycles of CHOP-like chemotherapy alone (CLC; n=411). Bulky and extranodal sites received additional radiotherapy.
- **Primary Outcome**: Event-free survival.
- **Results**: Patients receiving CCR had an increased 6-yr event-free survival compared with the CLC group (74.3% vs. 55.8%; p<0.0001). Event-free survival was affected by treatment group, presence of bulky disease, and age-adjusted International Prognostic Index (IPI). Overall survival was affected by treatment group and presence of bulky disease. Within the CCR group, a favourable subgroup (IPI=0, no bulk) and less favourable subgroup (IPI=1 or bulk, or both) could be defined; event-free survival was 84.3% vs. 71.0%.
- **Conclusion**: Rituximab added to six cycles of CHOP is an effective treatment for young patients with good-prognosis diffuse large B-cell lymphoma. The definition of two prognostic subgroups allows a more refined therapeutic approach to these patients than does assessment by IPI alone.
• **aggressive lymphoma**: goal of treatment is curative
  - combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma
  - radiation for localized/bulky disease
  - CNS prophylaxis with high-dose methotrexate if certain sites involved (testicular, nasopharyngeal)
  - relapse, resistant to therapy: high dose chemotherapy, BMT

• **highly aggressive lymphoma**
  - Burkitt Lymphoma: short bursts of intensive chemotherapy
  - "CODOX-M" chemotherapy regimen also often used ± IVAC
  - CNS prophylaxis and tumour lysis syndrome prophylaxis

**Complications**
- hypersplenism
- infection
- autoimmune hemolytic anemia and thrombocytopenia
- vascular obstruction (from enlarged nodes)
- tumour lysis syndrome (particularly in very aggressive lymphoma) – see H50

**Prognosis**
- follicular lymphoma: Follicular Lymphoma International Prognostic Index is used (5 adverse prognostic factors): age >60; number of nodal areas >4; elevated LDH; Ann Arbor stage III-IV; hemoglobin <120 g/L
  - based on calculated risk, mean 5 yr survival ranges from 53-91%
  - rarely curative, typically relapsing course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
- diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrand 2-4); elevated LDH; >1 extranodal site
  - based on calculated risk, mean 5 yr survival ranges from 26-73%
  - has ~40% rate of cure

Chronic Lymphocytic Leukemia (CLL)

**Definition**

- indolent disease characterized by clonal malignancy of mature B-cells

**Epidemiology**

- most common leukemia in Western world
- mainly older patients; median age 65 yr
- M>F

**Pathophysiology**

- accumulation of neoplastic lymphocytes in blood, bone marrow, lymph nodes and spleen

**Clinical Features**

- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms (≥1 of: unintentional weight loss ≥10% of body weight within previous 6 mo, temperature >38°C or night sweats for ≥2 wk without evidence of infection, extreme fatigue)
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (Coombs positive), ITP, hypogammaglobulinemia ± neutropenia
- bone marrow failure: late, secondary to marrow involvement by CLL cells

**Investigations**

- CBC: absolute lymphocytes >5 x 10^9/L with a CLL phenotype
- peripheral blood film
  - lymphocytes are small and mature
  - smudge cells
- flow cytometry (CD5, CD20, CD23, etc.)
- cytogenetics: FISH (dictates response to therapy and prognosis)
- bone marrow aspirate
  - lymphocytes >30% of all nucleated cells
  - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35%, worse prognosis) or mixed (25%)

**Natural History and Treatment**

- natural history: indolent but incurable, with slow progression; thus select gentlest treatment that will control symptoms
  - observation if early, stable, asymptomatic
  - intermittent chlorambucil or fludarabine chemotherapy combined with rituximab, chlorambucil in the elderly
  - corticosteroids, IVIG: especially for autoimmune phenomena
  - radiotherapy
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- 9 yr median survival, but varies greatly

Rouleaux formation on peripheral blood smear, if not artifact, denotes hyperglobulinemia (but not necessarily monoclonality).

Smudge cells are artifacts of damaged lymphocytes from slide preparation.
• prognosis predicted by Rai staging
  ▪ low risk: lymphocytosis in blood and bone marrow only
  ▪ intermediate risk: lymphocytosis with enlarged nodes in any site or splenomegaly, hepatomegaly
  ▪ high risk: lymphocytosis with disease-related anemia (<110 g/L) or thrombocytopenia (<100 x 10^9/L)

Complications
• bone marrow failure
• immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia, impaired T-cell function)
• polyclonal or monoclonal gammopathy (often IgM)
• hyperuricemia with treatment
• 5% undergo Richter’s transformation: aggressive transformation to diffuse large B-cell lymphoma (see Table 33)

Multiple Myeloma (MM)

Definition
• neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
• usually single clone of plasma cells, although biclonal myeloma also occurs. Rarely non-secretory

Epidemiology
• incidence 3 per 100,000, most common plasma cell malignancy
• increased frequency with age; median age of diagnosis is 68 yr; M>F

Pathophysiology
• malignant plasma cells secrete monoclonal antibody
  ▪ 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
    ▪ IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
    ▪ 15-20% produce free light chains or light chains alone found in either:
      – serum as an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
      – urine has Bence-Jones protein
  ▪ <5% are non-secretors

Clinical Features and Complications
• bone disease: pain (usually back), bony tenderness, pathologic fractures
  ▪ lytic lesions are classical (skull, spine, proximal long bones, ribs)
  ▪ increased bone resorption secondary to osteoclast activating factors such as PTHrP
• anemia: weakness, fatigue, pallor
  ▪ secondary to bone marrow suppression
• weight loss
• infections
  ▪ usually S. pneumoniae and Gram-negatives
  ▪ secondary to suppression of normal plasma cell function
• hypercalcemia: N/V, confusion, constipation, polyuria, polydipsia
  ▪ secondary to increased bone turnover
• renal disease/renal failure
  ▪ most frequently causes cast nephropathy (see Nephrology, NP30)
• bleeding
  ▪ secondary to thrombocytopenia, may see petechiae, purpura
  ▪ can also be caused by acquired von Willebrand disease
• extramedullary plasmacytoma
  ▪ soft tissue mass composed of monoclonal plasma cells, purplish colour
• hyperviscosity: may manifest as headaches, stroke, angina, MI
  ▪ secondary to increased viscosity caused by M protein
• amyloidosis
  ▪ accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
  ▪ may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)
• neurologic disease: muscle weakness, pain, paresthesias
  ▪ radiculopathy caused by vertebral fracture, extramedullary plasmacytoma
  ▪ spinal cord compression (10-20% of patients) is a medical emergency

Routine urinalysis will not detect light chains as dipstick detects albumin. Need sulfosalicylic acid or 24 h urine protein for immunofixation or electrophoresis.

Amyloid
The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues. Found in a variety of clinical disorders and can cause systemic (e.g. MM [light chains]) or localized amyloidosis (e.g. Alzheimer disease [AB amyloid]).
Investigations
- CBC:
  - normocytic anemia, thrombocytopenia, leukopenia
  - rouleaux formation on peripheral film
- biochemistry:
  - increased Ca\(^2+\), increased ESR, decreased anion gap, increased Cr, albumin, \(\beta_2\)-microglobulin
    (as part of staging), proteinuria (24 h urine collection)
- monoclonal proteins:
  - serum protein electrophoresis (SPEP): demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
  - urine protein electrophoresis (UPEP): demonstrates light chains in urine = Bence-Jones protein (15% only secrete light chains)
  - immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
  - serum free light chain quantification: kappa and lambda light chains, calculated ratio
- bone marrow aspirate and biopsy
  - often focal abnormality, greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for FISH or cytogenetics (prognostic implications)
- skeletal series (x-rays), MRI if symptoms of cord compression
  - presence of lytic lesions and areas at risk of pathologic fracture
  - bone scans are not useful since they detect osteoblast activity
- \(\beta_2\)-microglobulin, LDH and CRP are poor prognosticators

Diagnosis
- International Myeloma working group criteria
  1. serum or urinary monoclonal protein
  2. presence of clonal plasma cells in bone marrow or a plasmacytoma
  3. presence of end-organ damage related to plasma cell dyscrasia, such as:
     - increased serum Ca\(^2+\)
     - lytic bone lesions
     - anemia
     - renal failure

Treatment
- treatment is non-curative
- treatment goals:
  - improvement in quality of life (improve anemia, reverse renal failure, bony pain)
  - prevention of progression and complications
  - increase overall survival
- autologous stem cell transplant if <65 yr old
  - usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents
    (i.e. ImIDs or proteosome inhibitors)
- chemotherapy if >65 yr old or transplant-ineligible
  - melphalan, prednisone and novel agent (i.e. bortezomib)
- dexamethasone and bortezomib if ARF; bortezomib ± dexamethasone in light chain amyloidosis
- supportive management:
  - bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
  - local XRT for bone pain, spinal cord compression
  - kyphoplasty for vertebral fractures to improve pain relief and regain height
  - treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, erythropoietin for anemia, DVT prophylaxis
- all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient’s comorbidities and preferences

Prognosis
- International Staging System (\(\beta_2\)-microglobulin and albumin) used to stage and estimate prognosis
  - cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy)
- median survival based on stage, usually 16-70 mo

Light Chain Disease
15% of MM produce only light chains. Renal failure is a major problem. Kappa > lambda light chain has better prognosis.
Monoclonal Gammopathy of Unknown Significance (MGUS)

Definition
- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
  - incidence: 0.15% in general population, 5% of people >70 yr of age
  - asymptomatic

Diagnosis
- presence of a serum monoclonal protein (M-protein) at a concentration <30 g/L
- <10% plasma cells in bone marrow
- absence of hyperCalcemia, Renal insufficiency, Anemia, Bony disease related to the plasma cell proliferative process (absence of "CRAB")
- 0.3-1% of patients develop a hematologic malignancy each year
  - patients with M protein peak ≥15 g/L or patients with IgA or IgM MGUS are at higher risk of malignant transformation
  - patients with serum free light chains are at increased risk of malignant transformation
  - monitor with annual history, physical, CBC, Cr, calcium, albumin, serum protein electrophoresis (considered pre-malignant)

Lymphoplasmacytic Lymphoma (Waldenstrom’s Macroglobulinemia)

Definition
- proliferation of lymphoplasmacytoid cells
  - presence of monoclonal IgM paraprotein

Clinical Features
- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, retinal lesions
- key complication to avoid: hyperviscosity syndrome (see below)
  - because IgM (unlike IgG) confined largely to intravascular space

Investigations and Diagnosis
- bone marrow shows plasmacytoid lymphocytes
- bone lesions usually not present
- bloodwork rarely see hypercalcemia
- cold hemagglutinin disease possible: Raynaud's phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, high ESR if hyperviscosity not present

Management
- R-CVP, alkylating agents (chlorambucil), nucleoside analogues (fludarabine), thalidomide, rituximab, or combination therapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

Complications of Hematologic Malignancies

Hyperviscosity Syndrome

Definition
- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum lgs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenstrom's macroglobulinemia accounts for 85% of all cases of hyperviscosity syndrome.
**Clinical Features**
- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
  - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

**Treatment**
- plasmapheresis, chemotherapy

---

**Tumour Lysis Syndrome**

**Definition**
- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumour burden and high proliferative rate (high grade lymphoma, leukemia)

**Clinical Features**
- metabolic abnormalities
  - cells lyse, releasing K⁺, uric acid, PO₄³⁻ (increased levels)
  - PO₄³⁻ binds Ca²⁺ (decreased Ca²⁺)
- complications
  - lethal cardiac arrhythmia (increased K⁺)
  - acute renal failure (urate nephropathy, see Nephrology, NP30)

**Treatment**
- prevention
  - aggressive IV hydration
  - alkalinization of the urine
  - allopurinol or rasburicase
  - correction of pre-existing metabolic abnormalities
- dialysis

---

**Blood Products and Transfusions**

**Blood Products**
- RBCs, platelets and coagulation factors (frozen plasma [FP], cryoprecipitate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
  - centrifugation separates whole blood into RBCs and platelet-rich plasma
  - platelet-rich plasma is further fractionated into platelets and plasma
  - need to pool together multiple units to obtain therapeutic amounts
  - FP (previously known as FFP) is plasma frozen within 24 h of collection
  - cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures

**Specialized Products**
- irradiated blood products
  - prevent proliferation of donor T-cells in potential or actual BMT recipients
  - used for immunocompromised patients or for patients on purine analogue chemotherapy, first-degree relatives, HLA-matched products and intrauterine transfusions
- CMV-negative blood products
  - potential transplant recipients
  - neonates
  - AIDS patients
  - seronegative pregnant women

**Blood Groups**

<table>

</tbody>
</table>

In Canada, blood products are leukodepleted via filtration immediately after donation. Therefore it is considered:
- Low in lymphokines, resulting in a lower incidence of febrile nonhemolytic transfusion reactions
- CMV negative (because CMV is found in leukocytes)
Red Blood Cells

Packed Red Blood Cells
- stored at 4°C
- transfuse within 42 d of collection, otherwise cell lysis may result in hyperkalemia
- infuse each unit over 2 h, max of 4 h

Indications for packed RBC Transfusion
- Hb <70 g/L (7 g/dL); this may change as per patient’s tolerance or symptoms
  - maintain Hb between 70 and 100 g/L during active bleeds (7 g/dL to 10 g/dL)
- consider maintaining a higher Hb for patients with:
  - CAD/unstable coronary syndromes
  - uncontrolled, unpredictable bleeding
  - impaired pulmonary function
  - increased O₂ consumption

Selection of Red Cells for Transfusion
- when a need for RBC transfusion is anticipated, the following should be ordered:
  - group and screen
    - determines the blood group and Rh status of the recipient as well as the presence of autoantibodies vs. major/minor blood group antigens in the patient’s serum
  - crossmatch
    - involves mixing the recipient’s blood with potential donor blood and looking for agglutination
    - takes 30-45 min
- when blood is required, several options are available
  - 1st line: fully crossmatched blood (not always available in emergency situations)
  - 2nd line: donor blood of the same group and Rh status as the recipient
  - 3rd line: O- blood for females of reproductive age; O+ blood for all others

Platelets

Table 35. Platelet Products

<table>
<thead>
<tr>
<th>Product</th>
<th>Indication</th>

<td>Single donor platelets</td>
<td>Potential BMT recipients</td>
</tr>
<tr>
<td>HLA matched platelets</td>
<td>Refractory to pooled or single donor platelets, presence of HLA antibodies</td>
</tr>
</tbody>
</table>

- stored at 20–24°C
- random donor platelets are transfused from a pool of 4 units; this should increase the platelet count by ≥15 x 10⁹/L
- single donor platelets (transfused as single units) should increase the platelet count by 40–60 x 10⁹/L
- if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies, consumption (bleeding, sepsis) or hypersplenism may be present

Acute Blood Transfusion Reactions

IMMUNE

Acute Hemolytic Transfusion Reactions (AHTR)
- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation
- Most commonly due to incorrect patient identification
- Occurs immediately after transfusion
- Risk per unit of blood is <1 in 40,000
- Presents with fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- Acute renal failure (<24 h) and DIC
- Treatment:
  - Stop transfusion
  - Notify blood bank and check for clerical error
  - Maintain BP with vigorous IV fluids ± inotropes
  - Maintain urine output with diuretics, crystalloids, dopamine

Febrile Nonhemolytic Transfusion Reactions (FNHTR)
- Due to alloantibodies to WBC, platelets or other donor plasma antigens and release of cytokines from blood product cells
- Occurs within 0-6 h of transfusion
- Risk per unit of blood is 1 in 100 (minor), 1 in 10,000 to 40,000 (severe)
- Presents with fever ± rigors, facial flushing, headache, myalgia, hypotension
- Treatment:
  - Rule out hemolytic reaction or infection
  - If temperature <38°C, continue with transfusion but decrease rate and give antipyretics
  - If temperature >38°C, stop transfusion, give antipyretics and anti-histamine

Allergic Nonhemolytic Transfusion Reactions
- Alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- Occurs mainly in those with history of multiple transfusions or multiparous women
- Risk per unit of blood is 1 in 100
- Presents mainly as urticaria and occasionally with fever
- Can present as anaphylactoid reaction with bronchospasm, laryngeal edema and hypotension, but this occurs mainly in IgA deficient patients that have anti-IgA antibodies
- Treatment:
  - Mild: slow transfusion rate and give diphenhydramine
  - Moderate to severe: stop transfusion, give IV diphenhydramine, steroids, epinephrine, IV fluids and bronchodilators

Transfusion-Related Acute Lung Injury (TRALI)
- New-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
  - Insidious, acute onset of pulmonary insufficiency
  - Profound hypoxemia (PaO₂/FiO₂ <300 mmHg)
  - Bilateral pulmonary edema on CXR
  - Pulmonary artery wedge pressure <18 mmHg
  - No clinical evidence of left atrial hypertension
- Pathogenesis uncertain; perhaps due to binding of donor antibodies to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- Typically occurs 2-4 h post transfusion and resolves in 24-72 h
- Risk per unit of blood is 1:10,000
- Is currently the leading cause of transfusion-related morbidity and mortality
- Treatment: supportive therapy (oxygen)
- Inform blood bank; patient and donor testing will be arranged

DDx of Post-Transfusion Fever:
- Acute hemolytic transfusion reaction
- Febrile non-hemolytic transfusion reaction
- Bacterial contamination
- Allergy

DDx of Post-Transfusion Dyspnea:
- Circulatory overload (TACO)
- Transfusion-related acute lung injury (TRALI)
- Allergy (bronchospasm/anaphylaxis)
NONIMMUNE

Bacterial Infection
• Gram positive: S. aureus, S. epidermidis, Bacillus cereus
• Gram negative: Klebsiella, Serratia, Pseudomonas, Yersinia
• overall risk is 1 in 100,000 for RBC and 1 in 10,000 for platelets
• never store blood >4 h after bag has left blood bank
• treatment: stop transfusion, blood cultures, IV antibiotics, fluids

Transfusion Associated Circulatory Overload (TACO)
• due to impaired cardiac function and/or excessive rapid transfusion
• presents as dyspnea, orthopnea, hypotension, tachycardia, crackles at base of lung and increased venous pressure
• incidence is 1 in 700
• treatment: transfuse at lower rate, give diuretics and oxygen

Hyperkalemia
• due to K+ release from stored RBC
• risk increases with storage time and if blood is irradiated
• decreased risk if given fresh blood
• occurs in 5% of massively transfused patients
• treatment: see Nephrology, NP13

Citrate Toxicity
• occurs with massive transfusion in patients with liver disease – patients are unable to clear citrate from blood
• citrate binds to Ca2+ and causes signs and symptoms of hypocalcemia
• treatment: IV calcium gluconate (10 mL of 10%) for every 2 units of blood

Dilutional Coagulopathy
• occurs with massive transfusion (>10 units)
• pRBC contains no clotting factors, fibrinogen, cryoprecipitate or platelets
• treatment: FP, platelets and cryoprecipitate

Delayed Blood Transfusion Reactions

IMMUNE

Delayed Hemolytic
• due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
• level of antibody at time of transfusion is too low to cause hemolysis; later the level of antibody increases due to secondary stimulus and causes extravascular hemolysis
• occurs 5-7 d after transfusion
• presents as anemia and mild jaundice
• treatment: no specific treatment required; important to note for future transfusion

Transfusion-Associated Graft Versus Host Disease (GVHD)
• transfused T-lymphocytes recognize and react against “host” (recipient)
• occurs 4-30 d following transfusion
• most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
• presents as fever, diarrhea, liver function abnormalities and pancytopenia
• can be prevented by giving irradiated blood products

NONIMMUNE

Iron Overload
• due to repeated transfusions over long period of time (e.g. β-thalassemia major)
• can cause secondary hemochromatosis
• treatment: iron chelators or phlebotomy if not longer requiring blood transfusion and not anemic

Viral Infection Risk
• HBV <1 in 153,000
• Human T-lymphotropic virus (HTLV) <1 in 4,300,000
• HCV <1 in 2,300,000
• HIV <1 in 7,000,000
• other infections include EBV, CMV, WNV (West Nile virus)
Antiplatelet Therapy

Adverse Reactions of Heparin

- Hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- Heparin-induced thrombocytopenia: associated with venous or arterial thrombosis (see Table 22, H27)
- Osteoporosis: with long term use

Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)

- Increased bioavailability compared to normal heparin
- Increased duration of action
- SC route of administration
- Do not need to monitor aPTT
- Adverse reactions less common than UFH
- Patients with renal failure (CrCl <30) can accumulate LMWH, therefore must adjust dose
- Only partially reversible with protamine sulphate

**Principles of Microbiology**

**Bacteriology**

- **Bacteria Basics**
  - Bacteria are prokaryotic cells that divide asexually by binary fission
  - Chromosomal or plasmid DNA may be shared between bacteria through **conjugation** or **transduction**
  - Gram stain divides most bacteria into two groups based on cell wall
    - **Gram positive** (GP): thick, rigid layer of peptidoglycan
    - **Gram negative** (GN): thin peptidoglycan layer + thicker outer membrane composed of lipopolysaccharides
  - Clinical significance: GN thick outer membrane makes it resistant to penicillin's attack
  - Acid-fast bacilli: "acid-fast" due to high mycolic acid content in cell wall, e.g. *Mycobacteria, Nocardia*
  - "Atypical" bacteria: not seen on Gram stain and difficult to culture
    - Obligate intracellular bacteria: e.g. *Chlamydia*
    - Bacteria lacking cell wall: e.g. *Mycoplasma*
    - Spirochetes: e.g. *Treponema pallidum*
  - O2 can be either vital or detrimental to growth
    - Obligate aerobes: require O2
    - Obligate anaerobes: require environment without O2
    - Facultative anaerobes: can survive in environments with or without O2

**Mechanisms of Bacterial Disease**

1. Adherence to and colonization of skin or mucous membranes
   - E.g. fimbriae (pili): microfilaments extending through the cell wall – like burrs sticking to your clothes, they attach to epithelial cells e.g. *E. coli* in the urinary tract
2. Invasion or crossing normal epithelial barriers
3. Evasion of host defense system through inhibition of:
   - Phagocytic uptake: polysaccharide capsule (*S. pneumoniae, N. meningitidis, H. influenzae*) or surface proteins (*Staphylococcus, Streptococcus*)
4. Toxin production
   - Exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. *Clostridium*)
   - Endotoxins are structural components of GN bacterial cell wall, and may be shed by live cells or released during cell lysis
5. Intracellular growth
   - Obligate intracellular: *Rickettsia* and *Chlamydia*
   - Facultative intracellular: *Salmonella, Neisseria, Brucella, Mycobacteria, Listeria, Legionella*
6. Biofilm
   - An extracellular polysaccharide network forming mesh around the bacteria (e.g. *S. epidermidis*) which can coat prosthetic devices like IV catheters

**Figure 1. Bacteria morphology**

Gram positive bacteria have thick peptidoglycan layers.

### Figure 2. Laboratory identification of bacterial species
Virology

Viral Basics
- Viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - Infect cells and use host metabolic machinery to replicate
  - Nucleic acid can be double stranded (ds) or single stranded (ss)
  - Can be enveloped or naked
- Virions are mature virus particles that can be released into the extracellular environment
- Host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

Viral Disease Patterns
1. Acute infections (e.g. adenovirus)
   - Host cells are lysed in the process of virion release
   - Some produce acute infections with late sequelae (e.g. measles virus → subacute sclerosing panencephalitis)
2. Chronic infections (>6 mo): (e.g. HBV, HIV)
   - Host cell machinery is used to produce and chronically release virions
3. Latent infections
   - Viral genome remains latent in host cell nucleus
   - Can reactivate (e.g. HSV, VZV)

Mycology

Fungal Basics
- fungi are eukaryotic organisms
  1. yeast (unicellular)
  2. molds (also known as filamentous fungi) (multicellular with hyphae)
  3. dimorphic fungi (found as mold at room temperature but grow as yeast-like forms at body temperature)

<td>Cholesterol</td>
<td>–</td>
</tr>
<tr>
<td>Fungi</td>
<td>Ergosterol</td>
<td>Chitin (complex glycopoly saccharide)</td>
</tr>
</tbody>
</table>

Mechanisms of Fungal Disease
- primary fungal infection by:
  - overgrowth of normal flora (e.g. Candida species)
  - inhalation of fungal spores
  - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion aflatoxins)
- allergic reaction to fungi (e.g. bronchopulmonary aspergillosis)

Parasitology

Parasite Basics
- parasite: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycle requires more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed to the larval stage
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Tables 21 and 22 for examples of clinically important parasites

<tr>
<td>Multiplication</td>
</tr>
<tr>
<td>± Eosinophilia</td>
</tr>
<tr>
<td>Indefinite life span</td>
</tr>
</tbody>
</table>

*Adult ascaris (roundworm) does not cause eosinophilia

Characteristics of Parasitic Disease
- spectrum of disease ranging from asymptomatic to severe illness
- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic infection

Mechanisms of Parasitic Disease
1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B₁₂ deficiency in diphyllolothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
   - acute hypersensitivity (e.g. pneumonitis in Loeffler’s syndrome)
   - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
   - cytokine-mediated (systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
   - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
   - immune complex (e.g. nephritis of malaria, schistosomiasis)

*see Prevention of Infectious Diseases for further detail

Overview

- efforts to control the spread of infectious disease involves infection control and prevention measures in health care settings and public health measures outside of health care settings

Infection Control and Prevention Measures

1. surveillance for important nosocomial infections or problem organisms (e.g. surgical site infections, vascular access-related infections, C. difficile infections, colonization or infections due to antimicrobial resistant organisms (e.g. methicillin-resistant S. aureus) (see Population and Community Health, PH19 for a definition of active vs. passive surveillance)

2. routine practices (also known as standard precautions) used for all patients

- perform hand hygiene before and after seeing patient or patient environment contact, before aseptic procedures, and after body fluid exposure
- use gloves for any encounter with body fluids
- wear eye protection, mask, and gown for any procedures likely to generate splashes of body fluids
- do not recap sharps by hand and dispose of sharps in puncture-resistant container near point-of-use
- use mouthpieces for resuscitator bags instead of using mouth-to-mouth resuscitation
- discard soiled waste properly

3. additional precautions used for various syndromes or known infectious diseases

- contact precautions (private room, gown, gloves to be used routinely) (e.g. used for patients with C. difficile)
- droplet/contact precautions (private room, gown, gloves, eye protection, fluid-resistant mask) (e.g. used for influenza, meningitis due to Neisseria meningitidis)
- airborne precautions (negative-pressure private room with door closed, fit-tested N95 respirator) (e.g. used for TB, measles, VZV)
4. decolonization [e.g. topical and oral antimicrobials be used in an attempt to decolonize methicillin-resistant S. aureus (MRSA)]
5. outbreak investigations (see Population and Community Health, PH18)

Public Health Measures
1. vaccination
2. post-exposure prophylaxis (e.g. use of immunoglobulin or vaccination post-exposure to infectious disease agents in an attempt to reduce the likelihood or severity of disease)
3. reportable diseases (e.g. list of reportable communicable diseases that physicians are legally required to report to local public health officials) (see Population and Community Health, PH25)
4. contact tracing (tracking of individuals who have been exposed to a person with a communicable disease during its period of communicability)
5. quarantine (restriction of the activities or well persons who have been exposed to a person with a communicable disease during its period of communicability to prevent disease transmission during the incubation period if infection should occur)
6. outbreak investigation (see Population and Community Health, PH18)

Nosocomial Infections

- definition: infections acquired >48 h after admission to a health care facility or within 30 d from discharge
- risk factors: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
- patients with nosocomial infections have higher mortality, longer hospital stays, and higher health-care costs
- hand hygiene is an essential precaution

Table 7. Common Nosocomial Infectious Agents

<td>Contact precautions Stop culprit antibiotic therapy Supportive therapy (IV fluids) Mild-moderate disease: metronidazole PO/IV x 10-14 d Severe disease: vancomycin PO x 10-14 d Toxic megacolon: metronidazole IV + vancomycin PO (as above) and general surgery consult</td>
<td></td>
</tr>
<tr>
<td>Extended spectrum β-lactamases (ESBL e.g. <em>Escherichia coli</em>, <em>Klebsiella pneumoniae</em>)</td>
<td>Resistant to most β-lactam producing antibiotics e.g. penicillins, aztreonam and cephalosporins UTI Pulmonary infection Bacteremia Liver abscess in susceptible patients Meningitis</td>
<td>Blood, sputum, urine, or aspirated body fluid culture Imaging at infection site (CXR, CT, U/S)</td>
<td>Contact precautions depending on site of infection and institutional policies Depending on culture and sensitivity results, carbapenems can be used for empiric therapy</td>
<td></td>
</tr>
</tbody>
</table>
Respiratory Infections

Pneumonia

- see *Pediatrics*, P93
- see *Family Medicine*, FM18

Definition
- infection of the lung parenchyma

Etiology and Risk Factors
- impaired lung defenses
  - poor cough/gag reflex (e.g. illness, drug-induced)
  - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
  - impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)
- no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

*See *Pediatrics* P93, Table 45 for Common Causes and Treatment of Pneumonia at Different Ages

Clinical Features
- cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
- elderly often present atypically; altered LOC is sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles, increased fremitus, whisper pectoriloquy)
- features of parapneumonic effusion (decreased air entry, dullness to percussion, decreased fremitus) (see *Respirology*, R21)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage

Investigations
- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
- sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
- bronchoscopy ± washings for
  - (1) severely ill patients refractory to treatment or (2) immunocompromised patients

Treatment
- ABC, O₂, IV fluids, consider salbutamol (nebulized or MDI)
- determine prognosis and need for hospitalization and antibiotics

When Klebsiella causes pneumonia; see red currant jelly.

3 As of Klebsiella
- Aspiration pneumonia
- Alcoholics and diabetics
- Abscess in lungs

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger caliber and more vertical orientation of the right bronchus.

Table 12. IDSA/ATS Hospital/Ventilator/Healthcare-Associated Pneumonia Treatment Guidelines 2005

Table 12. IDSA/ATS Hospital/Ventilator/Healthcare-Associated Pneumonia Treatment Guidelines 2005

Prevention

- Public Health Agency of Canada recommends the following:
  - vaccine for influenza A and B recommended annually for all ages
  - pneumococcal polysaccharide vaccine (Pneumovax®) recommended for all adults >65 yr and in younger patients 24 mo of age and older at high risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia; congenital or acquired immunodeficiency)
  - pneumococcal conjugate vaccine (Prevnar-13®) is recommended for all children <5 yr, and for children and adolescents at high risk for invasive pneumococcal disease who are 5-17 yr who have not previously received Prevnar-13® (CDC recommends giving Prevnar-13® to all adults at high risk for invasive pneumococcal disease)
Influenza

Definitions and Etiology
- influenza virus A and B
- influenza A further divided into subtypes based on envelope glycoproteins:
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: human-origin A (H1N1) and B (H3N2) subtypes
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift (abrupt, major changes due to mixing of two different viral strains from different hosts)
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

</tbody>
</table>

Clinical Features
- incubation period 1-4 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, headache, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)

Investigations
- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for rapid antigen detection, DFA (Direct Fluorescent Antigen detection), RT-PCR (gold standard)
- serology: rarely used for clinical management

Treatment and Prevention
- primarily supportive unless severe infection or high-risk of complications (e.g. elderly, pulmonary or cardiac disease)
- neuraminidase inhibitors: zanamivir (Relenza®) and oseltamivir (Tamiflu®) for treatment and prophylaxis against type A and B
  - decreases duration (by 1-2 d) and severity of symptoms if given within <48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- M2-inhibitors: amantidine/rimantidine for treatment and prophylaxis against type A only when no longer recommended due to increased resistance
- vaccine for influenza A and B viruses is recommended annually for all ages
  - vaccine is reformulated each year to reflect circulating influenza A and B strains

Skin and Soft Tissue Infections

Cellulitis

Definition
- acute infection of the skin principally involving the dermis and subcutaneous tissue

Etiology
- common causative agents: S. aureus, β-hemolytic streptococci
- immunocompromised patients: may also include GN rods and fungi
- risk factors:
  - trauma with direct inoculation, recent surgery
  - peripheral vascular disease, lymphedema diabetes, cracked skin in feet/toes (tinea pedis)
Clinical Features
- pain, tenderness, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations
- CBC and differential, blood C&S if febrile
- skin swab ONLY if open wound with pus

Treatment
- antibiotics: cephalexin
- if extensive erythema or systemic symptoms, consider cefazolin IV
- limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition
- life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology
- Two main forms:
  - Type I: polymicrobial infection – aerobes and anaerobes (e.g. *S. aureus*, *Bacteroides*, *Enterobacteriaceae*)
  - Type II: monomicrobial infection with GAS

Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema
- edema, ± crepitus (subcutaneous gas from anaerobes), ± fever
- infection spreads rapidly
- patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
- late findings:
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of hemorrhagic bullae

Investigations
- a clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum CK (elevated CK usually means myonecrosis – a late sign)
- plain film x-ray (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

Treatment
- resuscitation with IV fluids
- emergency surgical debridements to confirm diagnosis and remove necrotic tissue
- IV antibiotics
  - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin
    - if MRSA is considered
  - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  - Type II (monomicrobial): penicillin G + clindamycin IV
  - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIG

Gastrointestinal Infections

Acute Diarrhea
- see *Gastroenterology*, G15
- see *Pediatrics*, P35
- see *Family Medicine*, FM26

Epidemiology
- one of five leading causes of death worldwide, according to World Health Organization
- significant morbidity in developed countries (over 900,000 hospitalizations in United States each year)
Definition
• passage of ≥3 loose or liquid stools/d or >200 g stool/d for >2 d but ≤14 d

Approach to Acute Diarrhea
• rationale:
  ▪ the vast majority of acute diarrhea is caused by infection
  ▪ in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
  ▪ investigations are costly and necessary only in certain circumstances
• therefore, the evaluation of acute diarrhea involves:
  ▪ identifying characteristics of the illness or patient that warrant further investigation
  ▪ assessing volume status to determine appropriate method of rehydration
• see Figure 7

Physical Exam
• volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
• abdominal exam: pain, guarding, peritoneal signs

Treatment
• rehydration is mainstay of treatment
  ▪ oral rehydration therapy
  ▪ IV rehydration if oral intake insufficient to replace fluid loss
• antidiarrheal agents reduce duration of diarrhea: loperamide, bismuth salicylate
  ▪ delays excretion of causative pathogens
  ▪ contraindications: diarrhea with fever, bloody stool or diarrhea caused by *Clostridium difficile*
• antibiotic therapy is rarely indicated because:
  ▪ most acute diarrheal illness is of viral etiology and is self-limited
  ▪ antibiotics can eradicate normal gut flora, predisposing to *C. difficile* infection
  ▪ antibiotics prolong the shedding of Salmonella and other causes of bacterial diarrhea
  ▪ in EHEC infection, antibiotics may increase the risk of HUS
  ▪ indications for antibiotic therapy are shown in Figure 7

Figure 7. Approach to acute diarrhea

</table>
Traveller’s Diarrhea

• see Acute Diarrhea, ID11

Epidemiology
• the most common illness to affect travellers
• up to 50% of travellers to developing countries affected in first 2 wk and 10-20% after returning home

Etiology
• bacterial (80-90%): E. coli most common (ETEC), Campylobacter, Shigella, Salmonella, Vibrio (non-cholera); wide regional variation (e.g. Campylobacter more common in Southeast Asia)
• viral: norovirus, rotavirus, and astrovirus account for 5-8%
• protozoal (rarely): Giardia, Entamoeba histolytica, Cryptosporidium, Cyclospora for ~10% in long-term travellers
• pathogen-negative traveller’s diarrhea common despite exhaustive microbiological work-up

Treatment
• rehydration is mainstay of therapy
  ▪ rehydrate with sealed beverages
  ▪ in severe fluid loss use oral rehydration solutions (1 package in 1L boiled or treated water)
• treat symptoms: antidiarrheal agents (e.g. bismuth salicylate, loperamide)
• empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
  ▪ note: there is increasing fluoroquinolone resistance in causative agents, especially in Southeast Asia

Prevention
• proper hygiene practices
  ▪ avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
  ▪ avoid untreated water
• bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
• CDC Guidelines: antibiotic prophylaxis not recommended
  ▪ increased risk of infection with resistant organisms
  ▪ high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents

---

</tr>
</tbody>
</table>

Bismuth salicylate (Pepto-Bismol®) can cause patients to have black stools, which may be mistaken for melena.
Dukoral®: oral vaccine that offers protection against *V. cholera* (efficacy ~80%) and ETEC (efficacy ~50-67%). Not recommended for routine use in travellers, but PHAC recommends that it may be considered in short-term travellers >2 yr who are high-risk (e.g. chronic illness) for whom there is an increased risk of serious consequences for traveller’s diarrhea (e.g. chronic renal failure, congestive heart failure, type 1 diabetes mellitus, inflammatory bowel disease), immunosuppressed, history of repeat traveller’s diarrhea, increased risk of acquiring traveller’s diarrhea (gastric hypochlorhydria or young children >2 yr).

### Chronic Diarrhea

- see *Gastroenterology*, G16

### Peptic Ulcer Disease (*H. pylori*)

- see *Gastroenterology*, G12

### Bone and Joint Infections

#### Septic Arthritis

**Routes of Infection**
- hematogenous (adults)
- contiguous osteomyelitis (children)
- direct inoculation via skin/trauma
- iatrogenic (surgery, arthroscopy, arthrocentesis)

**Etiology**
- gonococcal
  - *N. gonorrhoeae*: previously accounted for 75% of septic arthritis in young sexually active adults
- non-gonococcal
  - *S. aureus*: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
  - *Streptococcus* species (Group A and B)
  - Gram-negatives: affects neonates, elderly, IV drug users, immunocompromised
  - *S. pneumoniae*: affects children
  - *Kingella kingae*: affects children aged <2 yr since Hib immunization
  - *Salmonella* spp.: characteristic of sickle cell disease
  - coagulase-negative *Staphylococcus* species: prosthetic joints
- if culture negative: *Borrelia* spp. (Lyme disease) or *Tropheryma whippellii* (Whipple's disease)

**Risk Factors**
- gonococcal
  - age (<40 yr old), recent menses, pregnancy, MSM
- non-gonococcal
  - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
  - prosthetic joints/recent joint surgery
  - underlying joint disease (rheumatoid arthritis, osteoarthritis)
  - immunocompromise (diabetes, chronic kidney disease, alcoholism, cirrhosis)
  - loss of skin integrity (cutaneous ulcer, skin infection)
  - age >80 yr

**Clinical Features of Gonococcal Arthritis**

- two forms (although overlap often):
  - bacteremic form:
    - systemic symptoms: fever, malaise, chills
    - gonococcal triad: migratory polyarthralgias, tenosynovitis, dermatitis (pustular skin lesions)
  - septic arthritis form:
    - local symptoms in involved joint: swelling, warmth, pain, inability to bear weight, marked decreased in range of motion

**Clinical Features of Non-gonococcal Arthritis**

- acute onset of pain, swelling, warmth, decreased range of motion ± fever, chills
- most often in large weight bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)
Investigations

- consider rheumatologic causes for monoarthritis (see Rheumatology, RH3)
- gonococcal: blood C&S, as well as endocervical, urethral, rectal and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory: CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBC count (>15 000/mm³; likelihood of infection increases with increasing WBC count), PMNs >90%, culture positive
  - growth of N. gonorrheae from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

Treatment

- medical
  - empiric IV antibiotics (vancomycin + ceftriaxone) – delay may result in joint destruction
  - Gram stain guides subsequent treatment
  - gonococcal: ceftriaxone + azithromycin, for concurrent treatment of C. trachomatis
  - non-gonococcal: antibiotics against Streptococcus spp. (2 wk), S. aureus (4 wk IV minimum), or GN rods (4 wk)
- surgical drainage if: (see Orthopedics, OR10)
  - persistent positive joint cultures on repeat arthrocentesis
  - hip joint involvement
  - prosthetic joint
- daily joint aspirations until culture sterile; no need to give intra-articular antibiotics
- physiotherapy

Prognosis

- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: up to 50% morbidity (decreased joint function/mobility)

Diabetic Foot Infections

Etiology

- neuropathy, peripheral vascular disease and hyperglycemia contribute to foot ulcers that heal poorly and are predisposed to infection
- organisms in mild infection: S. aureus, Streptococcus spp.
- organisms in moderate/severe infection: polymicrobial with aerobes (S. aureus, Streptococcus, Enterococcus, GN bacilli) and anaerobes (Peptostreptococcus, Bacteroides, Clostridium)

Clinical Features

- not all ulcers are infected
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) or the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone = osteomyelitis
- infection severity:
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint)
  - severe = infection in a patient with systemic toxicity (fevers, chills, tachycardia, hypotension)

Investigations

- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages)
  - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity
  - if initial x-ray equivocal, do MRI or bone biopsy (most reliable test)

Treatment

- evaluate for early surgical debridement ± revascularization or amputation
- eliminate/reduce pressure and provide regular local wound care
- mild: cephalexin or clindamycin
- moderate or severe: clindamycin + ciprofloxacin PO or pip/tazo IV ± vancomycin if MRSA known or suspected
- encourage glycemic control

Osteomyelitis

- see Orthopedics, OR10

Intra-articular steroids are contraindicated until septic arthritis has been excluded.
Cardiac Infections

Infective Endocarditis (IE)

Definition
- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
- leaflet vegetation = platelet-fibrin thrombi, WBCs and bacteria

Risk Factors and Etiology
- predisposing conditions:
  - high risk: prosthetic cardiac valve, previous IE, congenital heart disease (unrepaired, repaired within 6 mo, repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  - moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  - low/no risk: secundum ASD or surgically repaired ASD < VSD, PDA, MV prolapse, IHD, previous CABG
  - opportunity for bacteremia: intravenous drug use (IVDU), indwelling venous catheter, hemodialysis, poor dentition, diabetes, HIV
- frequency of valve involvement MV >> AV > TV > PV
  - but in 50% of IVDU-related IE the tricuspid valve is involved

Table 16. Microbial Etiology of Infective Endocarditis Based on Risk Factors

Organisms in bold are the most common isolates.
1. Streptococcus includes mainly Viridans group streptococci
2. Other includes less common organisms such as:
   - Streptococcus bovis (usually associated with underlying GI malignancy, cirrhosis)
   - Culture-negative organisms including nutritionally-deficient streptococci, HACEK, Bartonella, Chlamydia, Legionella, Brucella
3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = Pseudomonas, saliva = oral flora, toilet water = GI flora)

Clinical Features
- systemic
  - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia
- cardiac
  - dyspnea, chest pain, clubbing (subacute)
  - regurgitant murmur (new onset or increased intensity)
  - signs of CHF (secondary to acute MR, AR)
- embolic/vascular
  - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  - focal neurological signs (CNS emboli), headache (mycotic aneurysm)
  - splenomegaly (subacute)
  - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
  - Osler’s nodes (painful, raised, red/brown, 3-15 mm on digits)
  - glomerulonephritis
  - arthritis
  - Roth’s spots (retinal hemorrhage with pale centre)

Diagnosis
- Modified Duke Criteria, see Table 17
  - definitive diagnosis if: 2 major, or 1 major + 3 minor, or 5 minor
  - possible diagnosis if: 1 major + 1 minor, or 3 minor
Table 17. Modified Duke Criteria

Major Criteria (2)

1. Positive blood cultures for IE
   - Typical microorganisms for IE from 2 separate blood cultures (Streptococcus viridans, HACEK group [see ID17], Streptococcus bovis, Staphylococcus aureus, community-acquired enterococci) OR
   - Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn >12 h apart or all of 3 or a majority of 4 or more separate blood cultures, with first and last drawn >1 h apart OR
   - Single positive blood culture for Coxiella burnetii or antiphase I IgG antibody titer >1:800

2. Evidence of endocardial involvement
   - Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve)
   - OR New valvar regurgitation (insufficient if increase or change in preexisting murmur)

Minor Criteria (5)

1. Predisposing condition (abnormal heart valve, IVDU)
2. Fever (38.0°C/100.4°F)
3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, ICH, conjunctival hemorrhages, Janeway lesions
4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler’s nodes, Roth’s spots
5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE

Investigations

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of endovascular infection (such as IE)
- repeat blood cultures (at least 2 sets) after 48 to 72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), RF (+), BUN/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- ECHO findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

Treatment

- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment
  - empiric antibiotic therapy if patient is unstable
    - first-line: vancomycin + gentamicin or ceftriaxone
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism and sensitivities
  - monitor for complications of IE (e.g. CHF, conduction block, new emboli) and complications for antibiotics (e.g. interstitial nephritis)
  - prophylaxis only for high risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure or musculoskeletal tissue
    - dental/respiratory: amoxicillin single dose 30-60 min prior; clindamycin if penicillin-allergic
    - skin/soft tissue: cephalaxin single dose 30-60 min prior; clindamycin if penicillin-allergic (modify based on etiology of skin/soft tissue infection)
  - surgical
    - most common indication is refractory CHF
    - other indications, include valve ring abscess, fungal etiology, valve perforation, unstable prosthesis, ≥ 2 major emboli, antimicrobial failure (persistently positive blood cultures), mycotic aneurysm, Staphylococci on a prosthetic valve

Prognosis

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess
- mortality: prosthetic valve IE (25-50%), non-IVDU S. aureus IE (30-45%), IVDU S. aureus or streptococcal IE (10-15%)
Neurological Infections

Meningitis

Definition

- inflammation of the meninges

Etiology

<table>

Risk Factors

- lack of immunization against *S. pneumoniae, H. influenzae type b*
- hematogenous spread after invasion from a mucosal surface (nasopharynx)
- parameningeal focus (otitis media, infection, sinusitis)
- penetrating head trauma
- anatomical meningeal defects – CSF leaks
- previous neurosurgical procedures, shunts
- immunocompromise (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
- contact with colonized or infected persons

Clinical Features

- neonates and children: fever, vomiting, lethargy, irritability, poor feeding
- older children and adults: fever, headache, neck stiffness, confusion, nausea and vomiting, lethargy, photophobia, altered level of consciousness, seizures, focal neurological signs, papilledema
- petechial rash on lower extremities with meningococcal meningitis

Investigations

- bloodwork: CBC and differential, electrolytes (for SIADH), blood C&S
- CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
- AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
- PCR for HSV, VZV, EBV, enteroviruses if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

Treatment

- bacterial meningitis is a medical emergency: do not delay antibiotics before CT or LP
- empiric antibiotic therapy:
  - age <1 mo: ampicillin + cefotaxime ± gentamicin IV
  - age >1 mo: vancomycin + ceftriaxone IV
  - add ampicillin IV (or TMP-SMX) if risk factors for infection with *L. monocytogenes* present: age >50, alcoholism, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics (see sidebar)
- benefit in all adults (including with pneumococcal meningitis) now uncertain

Brudzinski’s Sign

Passive neck flexion causes involuntary flexion of hips and knees.

Kernig’s Sign

Resistance to knee extension when hip is flexed to 90°.

Jolt Accentuation of H/A

Headache worsens when head turned horizontally at 2-3 rotations/s.

CSF Gram Stain Findings

- *S. pneumoniae – GP diplococci*
- *N. meningitidis – GN diplococci*
- *H. influenzae – Pleomorphic GN coccobacilli*
- *L. monocytogenes – GP rods*

Adjuvant Dexamethasone in Bacterial Meningitis: A Meta-analysis of Individual Patient Data

- *Lancet 2010;9:254-8*
- *Meta-analysis of randomized, double blind, placebo controlled trial.*
- *Population: 2029 patients from 6 trials, 833 <15 yr, 489 in 580, bacterial meningitis confirmed in 1639.*
- *Intervention: Antibiotics vs. without dexamethasone (first dose given within 20 min prior to or with first dose of antibiotics).*
- *Outcome: Death, death or any neurological sequelae, and death or severe bilateral hearing loss at first follow-up, death or severe neurological sequelae at 1 mo.*
- *Results: There was no difference in death (OR 0.97 (95% CI, 0.79–1.19)), death or severe bilateral hearing loss (OR 0.89, 95% CI, 0.73–1.10)). Death or severe neurological sequelae or any hearing loss (OR 0.92 (95% CI, 0.76–1.11)), or death or any neurological sequelae or any hearing loss (OR 0.91 (95% CI, 0.74–1.10)). However, among survivors, dexamethasone may reduce hearing loss (OR 0.77 (95% CI, 0.60–0.99), p=0.01).*  
- *Conclusion: The benefit of dexamethasone in acute bacterial meningitis is questionable with seemingly little effect in death or neurological sequelae. There may be some benefit on prevention of hearing loss.*

Does this Adult Patient Have Acute Meningitis? From The Rational Clinical Examination

- *JAMA 2009;302:3482857*
- *Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult meningitis.*
- *Population: 2029 patients from 5 trials, 833 <15 yr, HIV in 580, bacterial meningitis confirmed in 1639.*
- *Patient Data: Meta-analysis of randomized, double blind, placebo controlled trial.*
- *Intervention: Antibiotics vs. without dexamethasone (first dose given within 20 min prior to or with first dose of antibiotics).*
- *Outcome: Death, death or any neurological sequelae, and death or severe bilateral hearing loss at first follow-up; death or severe neurological sequelae at 1 mo.*
- *Results: There was no difference in death (OR 0.97 (95% CI, 0.79–1.19)), death or severe bilateral hearing loss (OR 0.89, 95% CI, 0.73–1.10)). Death or severe neurological sequelae or any hearing loss (OR 0.92 (95% CI, 0.76–1.11)), or death or any neurological sequelae or any hearing loss (OR 0.91 (95% CI, 0.74–1.10)). However, among survivors, dexamethasone may reduce hearing loss (OR 0.77 (95% CI, 0.60–0.99), p=0.01).*  
- *Conclusion: The benefit of dexamethasone in acute bacterial meningitis is questionable with seemingly little effect in death or neurological sequelae. There may be some benefit on prevention of hearing loss.*
Prevention
- see Pediatrics, P3
- immunization
  - children: immunization against *H. influenzae* (Pentacel®), *S. pneumoniae* (Synflorix®, Prevenar-13®), *N. meningitidis* (Menjugate®, Menactra®)
  - adult: immunization against *N. meningitidis* in selected circumstances (outbreaks, travel, epidemics) and *S. pneumoniae* (Pneumovax®) for high-risk groups
- prophylaxis: close contacts of patients infected with *H. influenzae* should be treated with rifampin if they live with an inadequately immunized or immunocompromised child <4 yr; ciprofloxacin, rifampin or ceftriaxone if close or household contact of a patient with *N. meningitidis*

Prognosis
- complications
  - headache, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness, death
- mortality
  - *S. pneumoniae* 25%; *N. meningitidis* 5-10%; *H. influenzae* 5%
  - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

Encephalitis

Definition
- inflammation of brain parenchyma

Etiology
- identified in only 40-70% of cases
  - when cause is identified, most common etiology is viral
  - e.g. HSV, VZV, EBV, enteroviruses, CMV, West Nile, HIV, mumps, measles, rabies, polio
  - bacteria: *L. monocytogenes*, *Mycobacteria*, spirochetes (Lyme, syphilis)
  - parasites: protozoa (e.g. *Toxoplasma*) and helminths (rare)
  - fungi: e.g. *Cryptococcus*
  - post-infectious (e.g. ADEM)

Pathophysiology
- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
- viruses may reach CNS via peripheral nerves (e.g. rabies, HSV)
- herpes simplex encephalitis
  - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial temporal and inferior frontal lobes
  - associated with HSV-1, but can also be caused by HSV-2

Clinical Features
- constitutional: fever, chills, malaise, nausea, vomiting
- meningeval involvement (meningoencephalitis): headache, nuchal rigidity
- parenchymal involvement: seizures, altered mental status, focal neurological signs
- herpes simplex encephalitis
  - acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  - temporal lobe involvement: behavioural disturbance
  - usually rapidly progressive over several days and may result in coma or death
  - common sequelae: memory and behaviour disturbances

Investigations
- CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses, and other less common viral etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. West Nile virus)
- imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected
- invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
  - CT/MRI: medial temporal lobe necrosis
  - EEG: early focal slowing, periodic discharges

Treatment
- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out
**Generalized Tetanus**

- see [Family Medicine, FM3](#)
- see [Pediatrics, P3](#)

**Etiology and Pathophysiology**

- caused by *Clostridium tetani*: motile, spore forming, anaerobic GP bacillus
- found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wound, burns, nonsterile surgeries or deliveries)
- upon inoculation, spores transform into *C. tetani* bacilli that produce tetanus toxin
  - toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

**Clinical Features**

- generalized tetanus
  - initially present with painful spasms of masseters (trismus or “lockjaw”)
  - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  - paralysis descends to involve large muscle groups (neck, abdomen)
  - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
  - autonomic hyperactivity
    - diaphoresis, tachycardia, hypertension, fever as illness progresses

**Investigations**

- culture wounds, CK may be elevated, BUN usually normal

**Treatment**

- stop toxin production
  - wound debridement to clear necrotic tissue and spores

- antimicrobial therapy: IV metronidazole

- neutralize unbound toxin with TIg

- supportive therapy: intubation, spasmolytic medications (benzodiazepines), quiet environment, cooling blanket

- control autonomic dysfunction: α- and β-blockade (e.g. labetalol), magnesium sulfate

**Prevention**

- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see [Pediatrics, P3](#)/[Emergency Medicine, ER17](#))

---

**Rabies**

**Definition**

- acute progressive encephalitis caused by RNA virus (family: *Rhabdoviridae*, genus *Lyssavirus*)

**Etiology and Pathophysiology**

- any mammal can transmit the rabies virus
  - most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the developing world
- transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
- virus travels via retrograde axonal transport from PNS to CNS
- virus multiples rapidly in brain, then spreads to other organs, including salivary glands
- development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
- infected animal can transmit rabies virus as soon as it shows signs of disease

**Clinical Features**

- 5 stages of disease:
  1. incubation period
  2. prodrome (<1 wk)
  3. influenza-like illness: low-grade fever, malaise, anorexia, N/V, headache, sore throat
  4. pain, pruritus, paresthesia may occur at wound site
  5. once prodromal symptoms develop, there is rapid, irreversible progression to death
- progression from prodrome to coma and death may occur without an intervening acute neurologic syndrome
3. acute neurologic syndrome: 3 types (<1 wk)
   A. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia, 
   hypersalivation, fever, seizures
      • painful pharyngeal spasms on encountering gust of air or swallowing water cause 
   aerophobia and hydrophobia, respectively
   B. paralytic: quadriplegia, loss of anal sphincter tone, fever
   C. atypical: rare
4. coma
   ▪ complete flaccid paralysis, respiratory and cardiovascular failure
5. death (within days to weeks of initial symptoms)

Investigations
• purpose of diagnosis by investigations is to limit patient contact with others and to identify 
  others exposed to the infectious source
• ante-mortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy, 
  serum, CSF
• post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion 
  bodies in neurons)

Treatment
• post-exposure prophylaxis depends on regional prevalence (contact Public Health) and 
  circumstances surrounding injury
• 3 general principles:
  ▪ wound care: clean wound promptly and thoroughly with soap and running water
  ▪ passive immunization: HRIg infiltrated into wound site, with any remaining volume 
    administered IM in anatomical site distant from vaccine administration
  ▪ active immunization: inactivated rabies virus vaccine (series of shots post-exposure)
• treatment is supportive once victim manifests signs and symptoms of disease

Prevention
• pre-exposure vaccination
  ▪ recommended for high risk persons: laboratory staff working with rabies, veterinarians, 
    animal and wildlife control workers, long-term travellers to endemic areas

Systemic Infections

Sepsis and Septic Shock

• see Respirology; R33

Definitions
• systemic inflammatory response syndrome (SIRS): 2 or more of
  (a) temperature <35ºC/95ºF or >38.5ºC/101.3ºF
  (b) heart rate >90 beats per minute
  (c) respiratory rate >20 breaths per minute or PaCO₂ <32 mmHg
  (d) WBC <4 x 10⁹/L or >12 x 10⁹/L or >10% bands
• sepsis: SIRS + proven or provable infection
• severe sepsis: sepsis + signs of end-organ dysfunction and hypoperfusion
• septic shock: severe sepsis + hypotension (<90 mmHg sBP), despite adequate fluid resuscitation

Pathophysiology
• causative agents are identified in only 50-70% of cases
• when organisms are identified, GP and GN organisms are the cause in 90% of cases (GP > GN > 
  fungal)
• primary bloodstream infection or secondary bacteremia → local immune response → immune 
  cells release pro-inflammatory cytokines that defend against pathogens → immune response 
  spreads beyond local environment → unregulated, exaggerated systemic immune response → 
  vasodilation and hypotension → involvement of tissues remote from the site of injury/infection 
  resulting in multiple major organ dysfunction → followed by a period immunoparalysis

Clinical Features
• history: fever, chills, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
• physical: abnormal vitals (fever, tachypnea, tachycardia, hypotension), local signs of infection

Investigations
• CBC and differential, electrolytes, BUN, creatinine, liver enzymes, ABG, lactate, INR, PTT, FDP, 
  blood C&S x3, urinalysis, urine C&S and cultures of any wounds or lines
• CXR (other imaging depends on suspicion of focus of infection)
**Treatment** (also see Respiratory, R33)  
- **respiratory support:** \( \text{O}_2 \) ± intubation  
- **cardiovascular support:** IV fluids, ± norepinephrine + ICU  
- **IV antibiotics** (empirical, depends on suspected source)  
  - start with broad spectrum antibiotics (piperacillin-tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology of infection, and local microbial susceptibilities (± aminoglycoside or vancomycin)  
  - if *Pseudomonas* unlikely: (ceftriaxone or piperacillin-tazobactam or meropenem) ± vancomycin  
  - if drug-resistant GN (e.g. *Pseudomonas*) possible: ceftazidime or meropenem or piperacillin-tazobactam + gentamicin  
  - narrow once susceptibilities are known  
- **hydrocortisone IV** in patients with septic shock unresponsive to fluid resuscitation and vasopressors

---

**Tuberculosis (TB)**

**Etiology, Epidemiology and Natural History**
- 1/3 of the world’s population is infected with TB  
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive and replicate in macrophages  
- inhalation and deposition in the lung can lead one of the following outcomes:  
  1. immediate clearance of the pathogen  
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 95% of infected people)  
  3. primary TB: symptomatic, active disease (represents 5% of infected people)  
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 2-3 yr of initial infection) at a pulmonary or extra-pulmonary site

**Risk Factors**
- social and environmental factors  
  - travel or birth in country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)  
  - aboriginal, crowded living conditions, low SES/homeless  
  - personal or occupational contact  
- host factors  
  - immunocompromised/immunosuppressed (including extremes of age)  
  - silicosis  
  - chronic renal failure requiring dialysis  
  - malignancy and chemotherapy  
  - substance abuse (e.g. drug use, alcoholism, smoking)

**Clinical Features**
- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients  
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms  
  1. pulmonary TB  
   - chronic productive cough ± hemoptysis  
   - CXR consolidation or cavitation, lymphadenopathy  
   - non-resolving pneumonia despite standard antimicrobial therapy  
  2. miliary TB  
   - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS  
   - CXR: multiple small 2-4 mm millet seed-like lesions throughout lung  
  3. extrapulmonary TB  
   - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningoitis, osteomyelitis (vertebral = Pott’s disease), adrenal (causing Addison’s disease), renal, ovary

**Investigations**
- screening for latent TB  
  - PPD/Mantoux skin tests  
    - both tests diagnose prior TB exposure; neither can diagnose or exclude active disease  
    - IFN-\( \gamma \) release assay (IGRA):  
      - in patients previously infected with TB, T-cells produce increased amounts of IFN-\( \gamma \) when re-exposed to TB antigen  
      - detects antigen not present in the BCG vaccine or in most types of non-tuberculous-mycobacteria (NTM), therefore fewer false positives

---

**Tuberculous Polyserositis**  
= pleural + pericardial + peritoneal effusions (usually from granuloma breakdown that spills TB into pleural cavity – very rare)
Canadian TB guidelines recommend IGRA as a confirmatory test if false positive or false negative test results are suspected, while American guidelines treat IGRAs as equivalent to the TB skin test and preferable in patients with a history of BCG vaccination or who may not return for skin test reading

- diagnostic tests/investigations for active pulmonary TB:
  - morning sputum on 3 consecutive days for acid-fast bacilli smear and culture
  - BAL
  - CXR:
    - nodular or alveolar infiltrates with cavitation (middle/lower lobe if primary, apical if secondary)
    - pleural effusion (usually unilateral and exudative) may occur independently of other radiograph abnormalities
    - hilar/mediastinal adenopathy (especially in children)
    - tuberculoma (semi-calcified well-defined solitary coin lesion 0.5-4 cm that may be mistaken for lung CA)
    - miliary TB
    - evidence of past disease: calcified hilar and mediastinal nodes, calcified pulmonary focus, pleural thickening with calcification, apical scarring

**Prevention**

- primary prevention
  - airborne isolation for active pulmonary disease
  - BCG vaccine
    - ~80% effective against pediatric miliary and meningeal TB
    - effectiveness in adults debated (anywhere from 0-80%)
    - routine use rarely recommended in Canadian population, however widely used in other countries
  - secondary prevention (defer in pregnancy unless mother is high risk)
    - likely INH-sensitive: isoniazid (INH) + pyridoxine (vit B6 to help prevent INH-associated neuropathy) x 9 mo
    - likely INH-resistant: rifampin x 4 mo

**Treatment of Active Infection**

- empiric therapy: INH + rifampin + pyrazinamide + ethambutol + pyridoxine
- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol + pyridoxine x 2 mo (initiation phase), then INH + rifampin + pyridoxine x 4 mo in fully susceptible TB (continuation phase), total 6 mo
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- empiric treatment of suspected MDR (multidrug resistant) or XDR (extensively drug-resistant) TB requires referral to a specialist
  - MDR = resistance to INH and rifampin ± others
  - XDR = resistance to INH + rifampin + fluoroquinolone + ≥1 of injectable, second-line agents
  - suspect MDR TB if previous treatment, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Public Health Agency of Canada website for more information: www.publichealth.gc.ca)

### Leprosy (Hansen’s Disease)

**Etiology**

- *Mycobacterium leprae*: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

**Clinical Features**

- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  - i. paucibacillary “tuberculoid” leprosy (intact cell-mediated immune response)
    - ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
    - early nerve involvement, enlarged peripheral nerves, neuropathic pain
    - may be self-limited, stable, or progress over time to multibacillary “lepromatous” form
  - ii. multibacillary “lepromatous” leprosy (weak cell-mediated immune response)
    - ≥6 lesions, symmetrical distribution
    - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
    - extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
  - iii. borderline leprosy
    - lesions and progression lies between tuberculoid and lepromatous forms
Investigations
- skin biopsy down to fat or slit skin smears for AFB, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

Treatment (WHO Treatment Regimens)
- paucibacillary: dapsone + rifampin monthly x 6 mo
- single skin lesion paucibacillary: single dose of rifampicin, ofloxacin, and minocycline
- multibacillary and borderline: dapsone + rifampin monthly + clofazimine monthly x 12 mo and low dose clofazimide once daily x 12 mo
- treatment of leprosy can cause an immune reaction to killed bacteria (e.g. erythema nodosum leprosum and reversal reaction): symptomatic management with NSAIDs if mild, prednisone with 6-12 wk taper if severe; thalidomide for erythema nodosum leprosum

Prognosis
- curable with WHO-approved treatment regimens
- complications: muscle atrophy, contractures, trauma/superinfection of lesions, crippling/loss of limbs, erythema nodosum leprosum
- long post-treatment follow-up warranted to monitor for relapse and immune reactions

Syphilis

Etiology
- Treponema pallidum: thick motile spirochetes historically detectable by dark-field microscopy (rarely done now)
- transmitted sexually, vertically, or parenterally (rare)

Clinical Features
- see Dermatology, D31 and Gynecology, GY28
- multi-stage disease
  i. primary syphilis (3-90 d post-infection)
    - painless chancre at inoculation site (any mucosal surface)
    - regional lymphadenopathy
    - acute disease lasts 3-6 wk, 25% progress to secondary syphillis without treatment
  ii. secondary syphilis = systemic infection (2-8 wk following chancre)
    - maculo-papular non-pruritic rash including palms and soles
    - generalized lymphadenopathy, low grade fever, malaise, headaches, aseptic meningitis, ocular/otic syphilis
    - condylomata lata: painless, wart-like lesion on palate, vulva or scrotum (highly infectious)
  iii. latent syphilis
    - asymptomatic infection that follows untreated primary/secondary syphillis
    - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
    - increased transmission risk with early latent; longer treatment duration required for late latent
  iv. tertiary syphilis (1-30 yr post-infection)
    - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
    - aortic aneurysm and aortic insufficiency
    - neurosyphilis: dementia, personality changes, Argyll-Robertson pupils, tabes dorsalis
  v. congenital syphilis
    - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
    - infants may be asymptomatic until age 2-5 yr then present with rhinitis, lymphadenopathy, hepatosplenomegaly, bone and cartilage degeneration (including saddle nose, saber shins), CN VIII deafness

Investigations
- screening tests: VDRL and RPR (non-treponemal), EIA (treponemal)
- confirmatory tests: FTA-ABS, MHA-TP, TPPA, TPI, dark field microscopy with silver stain
- LP for 3rd syphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms/RPR ≥1:32, or with HIV disease and late latent/unknown duration syphilis

Treatment
- for 1st, 2nd: early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3rd: late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if allergic to penicillin: doxycycline 100 mg PO bid x 14 d
- neurosyphilis: aqueous Penicillin G 18-24 million units/d IV x 14 d

Generalized STI Workup
- see Family Medicine, FM46
Lyme Disease

Etiology/Epidemiology
- spirochete bacteria: *Borrelia burgdorferi* (N. America), *B. garinii, B. afzelii* (Europe and Asia)
- transmitted by Ixodes tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- in Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick and Nova Scotia as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas
- infection usually requires >36 h tick attachment

Clinical Features
- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, headache, myalgias
  - erythema migrans (EM): expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) on thigh/groin/axilla
- stage 2 (early disseminated stage): weeks post-infection
  - CNS: aseptic meningitis, CN palsies (CNVII palsy), peripheral neuritis
  - cardiac: transient heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - acrodermatitis chronica atrophicans (due to *B. afzelii*)
  - neurologic: encephalopathy, meningitis, neuropathy

Investigations
- serology: ELISA, Western Blot

Prevention
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks and prompt removal of tick
- prophylaxis within 72 h of finding engorged attached nymphal tick that has been attached ≥36 h (approximately) in hyperendemic area (local rate of infection of ticks ≥20%): doxycycline

Treatment
- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone

Toxic Shock Syndrome (TSS)

Etiology
- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF). Course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- Staphylococcal TSS involves the production of superantigen TSST-1 (toxic shock syndrome toxin 1)
- Streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

Risk Factors
- Staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or caesarean or other surgical infections)
- Streptococcal: minor trauma, surgical procedures, preceding viral illness (chickenpox), use of NSAIDs

Clinical Features and Investigations
- acute onset, fever, sBP <90 mmHg
- Staphylococcal TSS:
  - rash with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
- Streptococcal TSS:
  - erythematous macular rash
  - isolation of GAS (e.g. blood, pleural, tissue biopsy, or surgical wound)
  - ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment
Treatment
• supportive: fluid resuscitation
• Staphylococcal: for methicillin-susceptible S. aureus: clindamycin + cloxacillin (IV); for MRSA: vancomycin x 10-14 d
• Streptococcal: IV penicillin and clindamycin and IV Ig

Cat Scratch Disease

Etiology
• Bartonella henselae: intracellular bacteria
• cat-to-human transmission via cat scratch/bite

Clinical Features
• skin lesion appears 3-10 d post-inoculation
• may be followed by fever, tender regional lymphadenopathy
• in some patients, organism may disseminate causing hepatosplenomegaly, neurologic symptoms
• usually self-limited

Investigations
• serology, lymph node biopsy

Treatment
• supportive in most cases
• azithromycin x 10-14 d in patients with moderate-severe disease or immunocompromise

Rocky Mountain Spotted Fever

Etiology
• Rickettsia rickettsii: obligate intracellular GN organism
• reservoir hosts: rodents, dogs
• vectors: Dermacentor ticks
• organisms cause inflammation of endothelial lining of small blood vessels, causing small hemorrhages and thrombi
• can cause widespread vasculitis leading to headache, CNS changes and can progress to death if treatment is delayed

Clinical Features
• usually occurs in summer following tick bite
• influenza-like prodrome: acute onset fever, headache, myalgia, nausea/vomiting, anorexia
• macular rash appearing on day 2-4 of fever
  ▪ begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  ▪ occasionally “spotless” (10% of patients)

Investigations
• skin biopsy and serology (indirect fluorescent antibody test)

Treatment
• doxycycline, usually 5-7 d course

West Nile Virus

Epidemiology
• virus has been detected throughout the United States and much of southern Canada
• overall case-fatality rates in severe cases are ~10%

Transmission
• primarily from mosquitoes that have fed on infected birds (crows, blue jays)
• transplacental, blood products (rare), organ transplantation

Clinical Features
• most are asymptomatic
• most symptomatic cases are mild (West Nile fever): acute onset of headache, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
• severe complications: encephalitis, meningoencephalitis and acute flaccid paralysis (especially in those >60 yr)
Investigations
- IgM antibody in serum or CSF (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- Viral isolation by PCR from CSF, tissue, blood and fluids (all have low sensitivity)
- CSF: elevated lymphocytes and protein if CNS involvement

Treatment and Prevention
- treatment: supportive
- prevention: mosquito repellent (DEET), drain stagnant water, community mosquito control programs

Fungal Infections

Skin and Subcutaneous Infections

Superficial Fungal Infections
- see Dermatology, D25

Dermatophytes
- see Dermatology, D26

Subcutaneous Fungal Infection

Pathophysiology
- fungi that naturally reside in soil and enter skin via traumatic break
- *Sporothrix schenckii*: most commonly affects gardeners injured by a rose thorn or splinter
  - causes subcutaneous nodule at point of entry
  - fungi may migrate up lymphatic vessels creating nodules along the way – “nodular lymphangitis”

Treatment
- oral azole (e.g. itraconazole)
- IV amphotericin B for severe or disseminated infection

Endemic Mycoses

Basics
- three major endemic mycoses in North America
  - histoplasmosis
  - blastomycosis
  - coccidioidomycosis
- thermally dimorphic organisms: mold in cold temperature (e.g. soil) and yeast at higher temperature (e.g. tissue)
- infection occurs through inhalation of spores (soil, bird droppings, vegetation) or inoculation injury
- all can cause pneumonia and may disseminate hematogenously
- may reactivate or disseminate during immunocompromise

Treatment
- common to all systemic mycoses
  - oral azole (e.g. itraconazole for mild-moderate local infection)
  - IV amphotericin B for systemic infection

Histoplasmosis is commonly associated with exposure to chicken coops, bird roosts and bat caves.

High Risk for Dissemination
- Immuno compromised (e.g. AIDS, steroids, TNF-α inhibitors)
- Pregnancy (3rd trimester)
- Diabetes
### Table 20. Endemic Mycoses

<table>
<thead>
<tr>
<th>Disease</th>
<th>Endemic Region</th>
<th>Clinical Features</th>
<th>Investigations</th>
</tr>
</thead>
</table>
| *Histoplasma capsulatum* | Ohio and Mississippi river valleys in central USA, Ontario, Quebec; widespread | Asymptomatic (in most people)  
Primary pulmonary  
- Fever, cough, chest pain, headache, myalgia, anorexia  
- CXR (acute): pulmonary infiltrates ± hilar lymphadenopathy  
- CXR (chronic): pulmonary infiltrates, cavitary disease  
Disseminated (rare)  
- Occurs primarily in immunocompromised patients  
- Spread to bone marrow (pancytopenia), GI tract (ulcers), lymph nodes (lymphadenitis), skin, liver, adrenals, CNS | Fungal culture, fungal stain  
Antigen detection (urine and serum) |
| *Blastomyces dermatitidis* | States east of Mississippi River, Northern Ontario and along the great lakes | May be asymptomatic  
Primary: acute or chronic pneumonia  
- Fever, cough, chest pain, chills, night sweats, weight loss  
- CXR (acute): lobar or segmental pneumonia  
- CXR (chronic): lobar infiltrates, fibronodular interstitial disease  
Disseminated  
- Spread to skin (verrucous lesions that mimic skin cancer, ulcers, subcutaneous nodules), bones (osteomyelitis, osteolytic lesions), GU tract (prostatitis, epididymitis) | Sputum smear and culture  
Direct examination of clinical specimens for characteristic broad-based budding yeast (sputum, tissue, purulent material) |
| *Coccidioides immitis*   | Deserts in southwest USA, northwest Mexico                                   | Primary  
- "Valley fever": subacute fever, chills, cough, chest pain, sore throat, fatigue that lasts for weeks to months  
- Can develop hypersensitivity with arthralgias, erythema nodosum  
Disseminated  
- Rare spread to skin (ulcers), joints (synovitis), bones (lytic lesions), meninges (meningitis)  
- Common opportunistic infection in patients with HIV | Sputum culture  
Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material) |

### Opportunistic Fungi

**Pneumocystis jiroveci (formerly P. carinii)**

**Microbiology**
- unicellular fungi
- previously classified as a protozoa

**Transmission**
- rarely person-to-person transmission
- most disease is due to reactivation of latent infection acquired by the respiratory route or reinfection by a different genotype
  - causes clinical disease in immunocompromised patients (steroid use, HIV)
  - 80% lifetime risk without prophylaxis in patients with CD4 count <200 cells/mm³

**Clinical Features**
- symptoms of pneumonia: fever, nonproductive cough, progressive dyspnea
- classic CXR (see sidebar)

**Investigations**
- demonstration of organism in induced sputum, bronchoalveolar lavage, or endotracheal aspirate (if intubated)

**Treatment and Prevention**
- oxygen to keep SaO₂ >90%
- antimicrobial options:
  - TMP/SMX (PO or IV) *First line*
  - dapsone and TMP
  - clindamycin and primaquine
  - pentamidine (IV)
  - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia (pO₂ <70 mmHg or A-a gradient O₂ >35 mmHg)
- prophylactic TMP/SMX for those at high risk of infection (HIV patients when CD4 <200 cells/mm³ or non-HIV immunocompromised patients under specific conditions)

**CXR in P. jiroveci**
- Bilateral, diffuse opacities
- CXR may be normal (20-30% cases)
- CT shows cysts (hence the name Pneumo "cystis") but almost never pleural effusions
**Cryptococcus spp.**

**Microbiology**
- encapsulated yeast found worldwide
- 2 human pathogenic species: *C. gattii, C. neoformans*

**Transmission**
- inhalation of airborne yeast from soil contaminated with pigeon droppings (*C. neoformans*) or certain tree species such as Eucalyptus or Douglas fir (*C. gattii*) may cause local infection in lung, asymptomatic or pneumonia
- may also spread hematogenously to the CNS, skin, bones and other organs
- *C. neoformans* tends to affect immunocompromised hosts
- *C. gattii* tends to affect immunocompetent hosts

**Clinical Features**
- pulmonary
  - usually asymptomatic or self-limited pneumonitis
  - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
  - frequently disseminates in HIV+ population
  - CNS: meningitis (leading cause of meningitis in patients with HIV)
  - skin: umbilicated papules that resemble large lesions of *Molluscum contagiosum*

**Investigations**
- serum cryptococcal antigen
- CSF for meningitis: India-ink stain, cryptococcal antigen test, culture to confirm
- blood C&S

**Treatment**
- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance

**Candida albicans**

**Microbiology**
- yeast forms with pseudohyphae at 20°C and germ tube formation at 37°C

**Transmission**
- normal flora of skin, mouth, vagina and GI tract
- risk factors for overgrowth:
  - immunocompromised state (diabetes, corticosteroids)
  - ICU patients (broad-spectrum antibiotic use, central venous catheters, TPN)

**Clinical Features**
- mucocutaneous
  - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see Gynecology, GY24), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  - small satellite lesions beyond the margin of the rash distinguish it from tinea or other conditions
- invasive
  - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease

**Treatment**
- thrush: nystatin suspension or pastilles for mild disease, fluconazole for severe disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles

**Aspergillus spp.**

**Microbiology**
- branching septate hyphae
- common species causing disease include *A. fumigatus, A. flavus*
Transmission
- ubiquitous in the air and the environment
- *Aspergillus* produces a toxin called aflatoxin that contaminates nuts, grains and rice

Clinical Features
- allergic bronchopulmonary aspergillosis (ABPA)
  - IgE-mediated asthma-type reaction with dyspnea, high fever and transient pulmonary infiltrates
  - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
  - ball of hyphae in a preexisting lung cavity
  - symptoms range from asymptomatic to massive hemoptysis
  - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes (“air crescent” sign)
- invasive aspergillosis
  - associated with prolonged and persistent neutropenia
  - pneumonia – most common
  - may disseminate to other organs: brain, skin
  - severe symptoms with fever, cough, dyspnea, pleuritic pain, tends to cavitate; fatal if not treated early and aggressively
  - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules
- mycotoxicosis
  - aflatoxin produced by *A. flavus* (nuts, grains, rice)
  - results in liver hemorrhage, necrosis and hepatocellular carcinoma formation

Treatment Options
- for invasive aspergillosis: voriconazole or amphotericin B
- surgical resection for aspergilloma and hemorrhage
- corticosteroids for ABPA

Parasitic Infections

Protozoa – Intestinal/Genitourinal Infections

Entamoeba histolytica (Amoebas)

Transmission
- reservoir: infected humans
- cysts by fecal-oral and food/waterborne transmission in areas of poor sanitation
- seen in immigrants, travellers, institutionalized individuals, Aboriginal Canadians, MSM

Clinical Features
i. asymptomatic carriers
ii. amoebic dysentery
  - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction and ulceration of large intestine
iii. amoebic abscesses
  - most common in liver (hematologic spread); presents with RUQ pain, weight loss, fever, hepatomegaly
  - can also occur in lungs and brain

Investigations
- serology, fecal/serum antigen testing, stool exam (for cysts and trophozoites), colon biopsy
- *E. histolytica* indistinguishable microscopically from the non-pathogen *E. dispar* (distinguish by specific stool antigen detection)

Treatment and Prevention
- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of cyst rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)
**Giardia lamblia**

**Transmission**
- reservoir: infected humans and other mammals
- food/waterborne (especially in the Rockies) and fecal-oral transmission of infectious cysts
- risk factors: travel, camping, institutions, day care centres, MSM

**Clinical Features**
- giardiasis (“beaver fever”)
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucus in stool

**Investigations**
- multiple stool samples (daily x 3 d) for microscopy, stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

**Treatment and Prevention**
- metronidazole, nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

**Trichomonas vaginalis**

**Transmission**
- sexual contact

**Clinical Features**
- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- trichomonas vaginitis (see Gynecology, GY25)
  - vaginal discharge (profuse, malodorous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

**Investigations**
- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

**Treatment**
- metronidazole for patient and partner(s)

**Cryptosporidium spp.**

**Transmission**
- reservoir: infected humans and a wide variety of young animals
- fecal-oral transmission by ingestion of cysts, waterborne
- risk factors: summer and fall, young children (day care), MSM, contact with farm animals, immunocompromise, immune reconstitution

**Clinical Features**
- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with nausea, vomiting, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)

**Investigations**
- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody

**Treatment and Prevention**
- supportive care only for immunocompetent hosts
- in HIV, try HAART to restore immunity; if fails, try nitazoxanide
- good personal hygiene, water filtration
Blood and Tissue Infections

Plasmodium spp. (Malaria)

Microbiology
- species include: *P. falciparum* (most common and most lethal), *P. vivax*, *P. ovale*, *P. malariae*, *P. knowlesi* (new species isolated from primates in Malaysia, potentially fatal)
- complex life cycle: human host for asexual reproduction and mosquito for sexual reproduction
- sporozoite from mosquitoes infect liver cells in which parasites multiply and are released as merozoites which infect RBCs causing disease
- *P. ovale* and *P. vivax* can produce dormant hypnozoites in the liver that may cause relapsing malarial attacks by reactivating (entering the erythrocytic cycle) after many months

Transmission
- reservoir: infected human
- transmission by the bite of the female Anopheles mosquito, vertical transmission and blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

Clinical Features
- flu-like prodrome
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs)
  - *P. vivax* and *P. ovale*: chills and fever q48h but can be variable
  - *P. malariae*: chills and fever q72h but can be variable
  - *P. falciparum*: less predictable fever interval, can be highly variable (>90% ill within 30 d)
- abdominal pain, diarrhea, myalgia, headache, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis

Complications
- *P. falciparum*: CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute renal failure, ARDS, primarily responsible for fatal disease
- *P. knowlesi*, and rarely *P. vivax* can be fatal

Investigations
- microscopy: blood smear q12-24h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
- rapid antigen detection tests

Treatment and Prevention
- *P. vivax*, *P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- *P. vivax*, chloroquine resistant: primaquine with quinine and doxycycline or tetracycline or mefloquine
- *P. malariae*, *P. knowlesi*: chloroquine
- *P. falciparum*: most areas of the world show chloroquine resistance
  - artesinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
  - atovaquone/proguanil combination (Malarone®)
  - quinine plus doxycycline, tetracycline or clindamycin
  - mefloquine and artesiminin resistance increasing in southeast Asia (check local resistance)
- prevented by antimalarial prophylaxis, bed nets, insect repellent

Trypanosoma cruzi

Transmission
- found in Mexico, South America and Central America
- transmission by Reduviid insect vector ("Kissing Bug"), which defecate on skin and tryptomastogotes in the stool usually rubbed into bite site by host (majority of infections)
- also transmitted via placental transfer, organ donation, blood transfusion and ingestion of contaminated food containing Reduviid insects (especially cane juice)

Clinical Features
- American trypanosomiasis (Chagas disease)
  - acute: usually asymptomatic, local swelling at site of inoculation ("Romanas sign"; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly and hepatosplenomegaloy
  - intermediate phase: asymptomatic but increasing levels of parasite and antibody in blood; most infected persons remain in this phase
  - chronic: can lead to chronic dilated cardiomyopathy, esophagomegaly and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

Trypanosoma cruzi

Transmission
- reservoir: infected human
- transmission by the bite of the female Anopheles mosquito, vertical transmission and blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

Clinical Features
- acute: usually asymptomatic, local swelling at site of inoculation ("Romanas sign"; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly and hepatosplenomegaloy
- intermediate phase: asymptomatic but increasing levels of parasite and antibody in blood; most infected persons remain in this phase
- chronic: can lead to chronic dilated cardiomyopathy, esophagomegaly and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

Complications
- *P. falciparum*: CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute renal failure, ARDS, primarily responsible for fatal disease
- *P. knowlesi*, and rarely *P. vivax* can be fatal

Investigations
- microscopy: blood smear q12-24h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
  - rapid antigen detection tests

Treatment and Prevention
- *P. vivax*, *P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- *P. vivax*, chloroquine resistant: primaquine with quinine and doxycycline or tetracycline or mefloquine
- *P. malariae*, *P. knowlesi*: chloroquine
- *P. falciparum*: most areas of the world show chloroquine resistance
  - artesinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
  - atovaquone/proguanil combination (Malarone®)
  - quinine plus doxycycline, tetracycline or clindamycin
  - mefloquine and artesiminin resistance increasing in southeast Asia (check local resistance)
- prevented by antimalarial prophylaxis, bed nets, insect repellent

Figure 9. Life cycle of Plasmodium spp.
Investigations
• wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

Treatment and Prevention
• acute: nifurtimox or benznidazole
• intermediate: increasing trend to treat as acute infection
• chronic: symptomatic therapy, surgery including heart transplant, or esophagectomy, colectomy, as necessary, may be a benefit to antiparasitic treatment
• insect control, bed nets

**Toxoplasma gondii**

Transmission
• acquired through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), vertical transmission, organ transplantation, whole blood transfusions

Clinical Features
• congenital
  ▪ result of acute primary infection of mother during pregnancy (TORCH infection – see Obstetrics, OB20)
  ▪ stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  ▪ initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult → blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
• acquired
  ▪ usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  ▪ infection remains latent for life unless reactivation due to immunosuppression
• immunocompromised (most commonly AIDS with CD4 <200)
  ▪ encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (headache and focal neurological signs)
  ▪ lymph node, liver and spleen enlargement and pneumonitis
  ▪ chorioretinitis

Investigations
• serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
• immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination
• negative serology in many AIDS patients (false negative due to decreased lymphocyte population)

Treatment and Prevention
• no treatment if: immunocompetent, not pregnant, no severe organ damage
• pregnancy: spiramycin to prevent transplacental transmission or pyrimethamine + sulfadiazine (add folic acid), avoid undercooked meat and refrain from emptying cat litter boxes
• HIV: pyrimethamine + sulfadiazine, AIDS prophylaxis: see HIV section
• eye disease, meningitis: corticosteroids
• proper hand hygiene, cook meat thoroughly

**Helminths**

**Roundworms – Nematodes**

### Trematodes/Flukes

#### Schistosoma spp.

**Species**
- *S. mansoni*, *S. hematobium*, *S. japonicum*

**Transmission**
- larvae (cercariae), released from snails, penetrate unbroken skin in infested fresh water (see Figure 13)
- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- eggs must reach fresh water to hatch; schistosomes cannot multiply in or pass between humans

**Clinical Features**
- most asymptomatic; symptoms seen in travelers (nonimmune)
- Swimmer’s itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - fever, hives, headache, weight loss, cough, abdominal pain, chronic diarrhea, eosinophilia

**Complications of Chronic Infection**
- caused by granulomatous response and fibrosis secondary to egg deposition by adults in the veins surrounding the intestine or bladder
- more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa
- *S. mansoni*, *S. japonicum*
  - worms in mesenteric vein, eggs in portal tracts of liver and bowel
  - heavy infections: intestinal polyps, portal and pulmonary hypertension, splenomegaly (2o to portal HTN), hepatomegaly
- *S. hematobium*
  - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
  - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
  - neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
  - pulmonary complications: granulomatous pulmonary endarteritis, pulmonary hypertension, cor pulmonale; especially in patients with hepatosplenic involvement

**Investigations**
- serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia)
- *S. mansoni*, *S. japonicum*: eggs in stool, liver U/S shows fibrosis, rectal biopsy
- *S. hematobium*: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

**Treatment and Prevention**
- praziquantel
- add glucocorticoid if acute schistosomiasis or neurologic complications develop
- proper disposal of human fecal waste, molluscicide, avoidance of infested water

### Ectoparasites

- scabies, lice
- see Dermatology, D27

### Travel Medicine

**General Travel Precautions**
- vector-borne: long-sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings and bed nets, repellents applied to skin (DEET)
- food/water: avoid eating raw meats/seafood, uncooked vegetables and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions, fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller's diarrhea (bismuth salicylate)
• standard vaccines up to date (HepB, MMR, tetanus/diptheria, varicella, pertussis, polio)
• travel vaccines: Hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera
• sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury through razors, tattoos, piercings

**Infectious Diseases to Consider**
- vector borne: malaria, dengue fever, Chikungunya fever, yellow fever, *Rickettsia*, West Nile virus, trypanosomiasis, Japanese encephalitis, tick-borne encephalitis, spotted fever, leishmaniasis
- sexually transmitted: HIV, HBV, syphilis, usual STIs
- zoonotic: rabies, hantavirus, tularemia, Q fever, anthrax, brucellosis
- airborne: TB
- food/water: HAV, HEV, brucellosis, typhoid, paratyphoid, amoebiasis, dysentery, traveller’s diarrhea, cholera, *Campylobacter* spp.
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

### Fever in the Returned Traveller

**Etiology**
- commonly identified causes of fever in returning traveller
  - parasitic: malaria (20-30%)
  - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: typhoid from *Salmonella* (2-7%), rickettsioses (3%)
  - diverse group of causative pathogens: traveller’s diarrhea (10-20%), RTI (10-15%), UTI/STI (2-3%)
- febrile illness in travellers can be caused by routine infections that are common in non-travellers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes: e.g. DVT, PE

**History**
- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip
- persons visiting friends and family more likely to be exposed to local population and pathogens
  - style of travel: lodgings, camping, adventure travelling
  - local population: sick contacts
  - transportation: use of animals
- exposure history
  - street foods, untreated water: increased risk of traveller’s diarrhea, enteric fever
  - uncooked meat/pasteurized dairy: increased risk of parasitic infection
  - body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  - increased risk of HBV, HCV, HIV, GC, *C. trachomatis*, syphilis
  - animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies
- fever pattern
  - incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
  - <21 d: consider malaria, typhoid fever, dengue fever, rickettsioses; exclude HBV, TB
  - >21 d: consider malaria, TB; exclude dengue fever, travellers’ diarrhea, rickettsioses
- body systems affected: GI, respiratory, CNS, skin

**Investigations**
- all travellers with fever should undergo the following tests:
  - bloodwork: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  - urine: urinalysis, urine C&S
  - special tests based on symptoms, exposure history, and geography
  - stool: C&S, O&P
  - CXR
  - dengue serology for IgM

---

**Important Exposures**

### Insect Bites
- *Mosquito*
  - *Plasmodium* spp. (Malaria)
  - Dengue
  - *Lymphatic filariasis* (Elephantiasis)
  - West Nile Encephalitis
  - *Yellow Fever*
  - *Japanese Encephalitis*
- *Tick*
  - *Borrelia burgdorferi* (Lyme Disease)
  - *Rickettsia rickettsii* (Rocky Mountain Spotted Fever)
- *Ry*
  - *Trypanosoma brucei* spp. (African sleeping sickness)
  - *Leishmania* spp. (Leishmaniasis)
  - *Bartonella bacilliformis* (Bartonellosis)
- *Rea*
  - *Vesicular Plague*
  - *Yersinio fermentans* (Plague)

### Mammal Bites
- *Dog/ Cat*
  - Rabies, Pasteurella, anerobes, *Streptococcus*, *S. aureus*
  - *Human*
  - *Streptococcus*, *S. aureus*, oral anerobes, *Eikenella*

### Oral Exposures
- *Unpasteurized milk*
  - *Listeria*
  - *Bacillus subtilis*, *non-tuberculosis mycobacteria*, *Salmonella*, *E. coli*, *Listeria*

### Undercooked meat
- *Entanobacteria*, *protozoa*
  - *Clostridium*
  - *Hep A/E*, *Norwalk*, *cholera*, *Salmonella*, *Shigella*, *Giardia*, *E. coli*, *Salmonella*

### Environmental Exposures
- *Freshwater*
  - *Leptospirosis*, *schistosomiasis*, *Acanthamoeba*, *Naegleria fowleri*
  - *Soil*
  - *Naegleria fowleri*, *Eikenella*

For up to date information on geographic and seasonal patterns of disease and travel advisories, check the website for the United States Centers for Disease Control and Prevention (www.cdc.gov/travel) or Foreign Affairs Canada (travel.gc.ca).
Etiology of Classic FUO

- infectious causes (~30%)
  - TB: extra-pulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvis, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - uncommon: viral (CMV, EBV), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin’s) and leukemias, also multiple myeloma, myelodysplastic syndrome
  - solid tumours: RCC (most common), also breast, liver (hepatoma), colon, pancreas or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still’s disease
- miscellaneous (~20%)
  - drugs, factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- unknown despite investigations in 30-50% despite detailed work-up

Etiology of Classic FUO

- infectious causes (~30%)
  - TB: extra-pulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvis, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - uncommon: viral (CMV, EBV), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin’s) and leukemias, also multiple myeloma, myelodysplastic syndrome
  - solid tumours: RCC (most common), also breast, liver (hepatoma), colon, pancreas or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still’s disease
- miscellaneous (~20%)
  - drugs, factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- unknown despite investigations in 30-50% despite detailed work-up

Causes of Nosocomial FUO

- B, C, D, E
- Bacterial and fungal infections of respiratory tract and surgical sites
- Catheters (intravascular and urinary)
- Drugs
- Emboli

Anti-Drugs that may Cause Fever:
- Anti-microbials (sulfonamides, penicillins, nitrofurantoin, antimicrobials)
- Anti-hypertensives (hydralazine, methylxanthine)
- Anti-epileptics (barbiturate, phenytoin)
- Anti-arrhythmics (quinine, procainamide)
- Anti-inflammatory (NSAIDs)
- Anti-thrombotic (ASA)
- Anti-histamines
- Anti-thyroid
Approach to Classic FUO
- careful history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
  - bloodwork: CBC and differential, electrolytes, BUN, Cr, calcium profile, LFTs, ESR, CRP, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood smear
  - cultures: blood (x 2 sets), urine, sputum, stool C&S, O&P, other fluids as appropriate
  - serology: HIV, monospot, CMV IgM
  - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- if no diagnosis with the above, consider empiric therapy vs. watchful waiting
  - without intervention: patients that remain undiagnosed despite extensive work-up have good prognosis

Infections in the Immunocompromised Host
- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent
- type of immunsuppression predicts probable spectrum of agents

Factors that Compromise the Immune System
- general: age (very young or elderly), malnutrition
- immune disease: HIV/AIDS, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

Table 25. Types of Immunocompromise

</tr>
<tr>
<td>Neutrophil Function</td>
<td>Myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease</td>
<td>Catalase-producing organisms (Staphylococcus, Serratia, Nocardia, Aspergillus)</td>
</tr>
</tbody>
</table>

Febrile Neutropenia (FN)

Definition
- fever (≥38.3°C/101°F or ≥38.0°C/100.4°F for ≥1 h) and one of:
  - ANC <0.5 OR ANC <1.0 but trending down to 0.5

Pathophysiology
- decreased neutrophil production
  - marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodysplastic syndromes
  - iatrogenic: cancer chemotherapy, radiation, drugs
  - deficiencies: vitamin B₁₂, folate
  - increased peripheral neutrophil destruction
  - autoimmune: Felty’s syndrome, SLE, antineutrophil antibodies
  - splenic sequestration

Epidemiology/Etiology
- most common life-threatening complication of cancer therapy
- 8 cases per 1000 cancer patients per year in the US
- causative organism identified only 1/3 of the time
- GN (especially Pseudomonas) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially Candida, Aspergillus)
Investigations
- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region
- blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports, ± sputum C&S and NP swab for respiratory viruses
- CBC and differential, Cr, BUN, electrolytes, AST/ALT, total bilirubin

Treatment
- most hospitals have their own specific protocol; one example is presented below

**Figure 14. Example of treatment protocol for febrile neutropenia**

### Infections in Solid Organ Transplant Recipients
- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant:
  - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant:
  - viral (especially CMV, EBV, VZV)
  - fungal (especially *Aspergillus, Cryptococcus, P. jiroveci*)
  - protozoan (especially *Toxoplasma*"
  - unusual bacterial/mycobacterial infections (especially TB, *Nocardia, Listeria*)

Prophylactic Vaccinations Given Before Transplant
- to all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B vaccines
- if low titre or poor documentation: MMR, polio, varicella vaccination (with booster 4-8 wk later)

### Immune Reconstitution Syndrome (IRS)

**Definition**
- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system
Etiology
- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in HIV/AIDS or immunosuppressed patients starting antiretroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation
- can occur in response to multiple infections:
  - Mycobacteria (tuberculosis, avium complex)
  - Cryptococcus
  - Pneumocystis
  - Toxoplasma
  - HBV and HCV
  - Herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - Molluscum contagiosum
- clinical features are dependent on the type and location of the pre-existing infection
- thought to be worse with quick increase in CD4 count and with lower pre-treatment CD4 count
- non-HIV conditions with documented IRS: solid organ transplant recipients, post-partum women, neutropenic patients, anti-TNF therapy

Epidemiology
- in HIV patients starting HAART, IRS reported to affect ~10%

Investigations
- IRS is a diagnosis of exclusion
- rule out drug reaction, patient non-adherence, drug resistance

Treatment
- continue HAART therapy in HIV patients with mild-moderate symptoms, but consider discontinuation if symptoms are life-threatening or potentially irreversible
- treat underlying infection; initiate treatment for some infections prior to HAART initiation
- consider starting corticosteroids/NSAIDs to decrease inflammatory response

HIV and AIDS

Epidemiology

Canadian Situation (Public Health Agency of Canada, 2012)
- estimated 71,300 Canadians living with HIV infection at the end of 2011, 25% unaware of HIV-positive status
- estimated 3,175 new infections occurred in 2011: MSM account for 47% of cases, IVDU 17%

Global Situation (WHO Global Summary of the HIV/AIDS Epidemic, December 2010)
- estimated 34.0 million people living with HIV/AIDS in 2010
- estimated 2.7 million newly infected in 2010
- estimated 1.8 million AIDS-related deaths in 2010

Definition and Pathophysiology
- human immunodeficiency virus (HIV) is a retrovirus that causes progressive immune system dysfunction which predisposes patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp1 and gp120 glycoproteins), matrix (p17) and capsid (p24) enclosing 2 single-stranded copies of RNA + enzymes in its core (see Figure 15)
- virion glycoproteins bind CD4 and CXCR4/CCR5 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by reverse transcriptase; dsDNA is integrated into host genome
- virus DNA transcribed during host replication and new virions are produced
- virions bud out of host cell, incorporating host cell membrane
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, increased cell turnover

Figure 15. HIV viral particle

**Natural History**

![Figure 16. Relationships between CD4 T cell count, viral load, and anti-HIV antibodies](image)

**Acute (Infection) Retroviral Syndrome (ARS)**
- 40-90% experience an acute "mononucelosis like" illness (fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, headaches, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high risk of transmission

**Asymptomatic (Latent) Stage**
- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count: 500-1100 cells/mm³
- CD4 count drops 60-100 cells/mm³ per year
- by 10 yr post-infection, 50% have AIDS, 30% demonstrate milder symptoms and <20% are asymptomatic if left untreated

**AIDS Definition in Canada**
- HIV-positive AND
- one or more clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. PJP (previously PCP), esophageal candidiasis, CMV, MAC, TB, toxoplasmosis), malignancy (Kaposi's sarcoma, invasive cervical cancer), wasting syndrome OR
- first CD4 <200 (or <15%)

Laboratory Diagnosis

- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo
- initial screening test: enzyme linked immunosorbent assay (ELISA) detects serum antibody to HIV; sensitivity >99.5%
  - some jurisdictions (e.g. Ontario) use combination Ag/Ab test as screen (tests for p24 antigen and HIV antibody)
- confirmatory test: if positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%
- rapid (point of care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology
- p24 antigen: detection by ELISA may be positive during "window period" before antibodies become detectable; combined with standard antibody test in some jurisdictions

Management of the HIV-Positive Patient

- verify positive HIV test
- complete baseline history and physical examination, then follow-up every 3 mo
- laboratory evaluation
  - routine CD4 count to measure status of the immune system
  - routine HIV-RNA levels (viral load)
    - also important indicator of effect of anti-retroviral (ARV) therapy
  - baseline HIV resistance testing to guide ARV therapy
  - HLA-B*5701 to reduce risk of abacavir hypersensitivity
  - baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
  - baseline serologies (hepatitis A, B and C, syphilis, toxoplasma, CMV, VZV)
  - routine biochemistry and hematology; CXR
  - annual fasting lipid profile and fasting glucose (due to HAART side effects)
- education
  - regular follow-up on CD4 counts and viral loads (q3-4mo) as well as strict adherence with ARVs improves prognosis
  - prevention of further transmission through safer sex and clean needles for injection drug use
  - HIV superinfection (transmission of different HIV strains from another HIV+ person) can rarely occur so barrier protection during sex is still recommended
- health care maintenance
  - assessment for counseling needs and referral for psychiatric or social concerns
  - vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative)
  - annual screening (PAP smear, STIs as applicable)
  - management of comorbid conditions (e.g. blood pressure monitoring, smoking cessation, alcohol/drug use)

SS = single strength; DS = double strength
Highly Active Antiretroviral Treatment (HAART)

Overall Treatment Principles
• in asymptomatic patients: initiate HAART when CD4 <350; ongoing debate about when to initiate HAART when CD4 is between 350-500 or >500
• current guidelines differ in various industrialized countries – see 2008 OARAC Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents
  http://aidsinfo.nih.gov/contentfiles/AdultandAdolescentGL.pdf
• other indications for initiating therapy include opportunistic infection/malignancy, pregnancy, HIV-associated nephropathy, HIV-associated thrombocytopenia, need for hepatitis B therapy in HBV co-infected patients
• consider starting treatment early if HCV co-infection, high HIV viral load, co-morbid conditions (e.g. cardiovascular disease)
• consider results of baseline resistance testing and complete ARV treatment history before (re-) initiating HAART
• goal: keep viral load <40 copies/mL; viral load should decrease 10-fold within 4-8 wk and be undetectable by 6 mo and restore immunological function
• secondary benefit of initiating therapy is 96% reduction in risk of transmitting HIV to sexual partners

HAART Recommendations for Treatment of Naïve Patients
• 2 NRTIs + 1 NNRTI/PI (boosted with ritonavir) or INSTI

Treatment Failure
• defined clinically (HIV progression), immunologically (failure to increase CD4 count by 25-50 over first year of treatment or CD4 decrease >100 over 1 yr), or virologically (failure to achieve viral load <40 copies/mL after 6 mo)
• ensure that viral load >40 is not just a transient viremia or ‘blip’

</table>

*Standard of care is to pharmacology boost most PIs with ritonavir to increase concentrations
Figure 17. Mechanism of HIV replications

**TARGET SITES FOR ANTIRETROVIRAL DRUGS**
- (A) Fusion inhibitor
- (B) CCR5 antagonist
- (C) Nucleoside reverse transcriptase inhibitors (NRTIs)
- (D) Integrase strand transfer inhibitors (INSTIs)
- (E) Protease inhibitors (PIs)

**PROCESS OF MULTIPLICATION**
1. Binding
2. Fusion and uncoating
3. Reverse transcription
4. Integration
5. Translation
6. Assembly and budding
7. Maturation

**Tropism Testing**
- In addition to CD4, HIV requires a co-receptor (either CCR5 or CXCR4) to enter cells
- CCR5 antagonists (e.g. Maraviroc) only work if virus is CCR5-tropic
- Tropism test required prior to initiating CCR5 antagonists

**Prevention of HIV Infection**
- education, including harm-reduction:
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm prevention for injection drug users: avoid sharing needles
- treatment of HIV+ women with HAART during the 2nd and 3rd trimester of pregnancy and AZT during delivery followed by AZT treatment of the infant for 6 wk (decreases maternal-fetal transmission from 25% to <3%)
- universal blood and body precautions for health care workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV although additional data needed
- HAART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation
Types of Testing

1. Nominal/name-based HIV testing
   - the person ordering the test knows the identity of the person being tested for HIV
   - the HIV test is ordered using the name of the person being tested
   - person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
   - the test result is recorded in the health care record of the person being tested

2. Non-nominal/non-identifying HIV testing
   - similar to nominal/name-based testing on all points except:
     - the HIV test is ordered using a code or the initials of the person being tested

3. Anonymous testing
   - available at specialized clinics
   - the person ordering the HIV test does not know the identity of the person being tested
   - the HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
   - test results are not recorded on the health care record of the person being tested

HIV Pre- and Post-test Counselling

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV+ patients should be connected with local support services

A Simplified Look at Antibiotics

- general overview, see Table 30 for more details

1. Penicillins (most Streptococcus, N. meningitidis, many oral anaerobes except B. fragilis)

   - [Image: Figure 18. Penicillins]

   Penicillin G (IV)/Penicillin V (PO)
   - Ampicillin (IV)/Amoxicillin (PO)
     - + Enterococcus and HiPLESS*
   - Cloxacillin
     - + MSSA but ↓ Streptococci
   - Amoxicillin-clavulanate
     - + Pseudomonas and Enterobacter
   - Piperacillin
     - Piperacillin-tazobactam

   *HiPLESS = H. influenza, Proteus, Listeria, E. coli, Salmonella, Shigella

2. Cephalosporins (PO/IV)
   - 1st generation: cephalaxin/cefazolin (mostly GP, some GN)
   - 2nd generation: cefuroxime/cefuroxime (some GP and some GN, *anaerobes)
   - 3rd generation: cefixime/cefotaxime, ceftriaxone (good Streptococcal coverage, mostly GN) and ceftazidime (no GP, mostly GN, *Pseudomonas*)
   - 4th generation: --/cefepeime (most GP, most GN, *Pseudomonas*)

3. Aminoglycosides (GN aerobic bacilli)
   - gentamicin
   - tobramycin
   - amikacin

4. Macrolides [GP, Hemophilus, and atypical bacteria (Legionella, Chlamydia, Mycoplasma)]
   - erythromycin
   - clarithromycin
   - azithromycin

Early identification of HIV is essential for patients to receive the maximal benefit from ARVs.
5. Fluoroquinolones (GN – although resistance becoming a huge problem)
   - ciprofloxacin (+ Pseudomonas)
   - norfloxacin (for UTI only)
   - respiratory fluoroquinolones (some GP, GN, "atypicals", Legionella, Mycoplasma, Chlamyphila)
   - levofloxacín
   - moxifloxacin (+ anaerobes)

6. Carbapenems (broad coverage: GP, GN and anaerobes)
   - imipenem (+ Pseudomonas)
   - meropenem (+ Pseudomonas)
   - ertapenem

7. Others
   - doxycycline/tetracycline (GP, syphilis, Chlamyphila, Rickettsia, Mycoplasma)
   - vancomycin (all GP and C. difficile – the oral form)
   - linezolid (for resistant GP infections)
   - clindamycin (most GP, GN anaerobes)
   - TMP/SMX (most S. aureus incl. MRSA, GN aerobes, Pneumocystis)
   - nitrofurantoin (GN bacilli, S. saprophyticus, Enterococcus)
   - linezolid (for resistant GP infections)
   - treatment for C. Difficile: metronidazole OR oral vancomycin; consider both in serious infection

Antimicrobials

Antibiotics

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S
    - if causative organism identified, use antibiotic to which organism is sensitive
    - if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

Reasons for Combination Therapy

- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. Enterococcus spp. causing endocarditis)
- To prevent emergence of resistance

Acronyms

AXR  abdominal x-ray
CT  computed tomography
CTA  computed tomographic angiogram
DEXA  dual-energy x-ray absorptiometry
DSA  digital subtraction angiography
DWI  diffusion-weighted image
ERCP  endoscopic retrograde cholangiopancreatography
FLAIR  fluid-attenuated inversion recovery
HIDA  hepatobiliary iminodiacetic acid
HSQ  hysterosalpingogram
IVP  intravenous pyelogram
MRA  magnetic resonance angiogram
MRCP  magnetic resonance cholangiopancreatography
MRI  magnetic resonance imaging
MUGA  multiple gated acquisition scan
PBD  percutaneous biliary drainage
PET  positron emission tomography scan
PTA  percutaneous transluminal angioplasty
RAIU  radioactive iodine uptake
SPECT  single photon emission computed tomography
TRUS  transrectal ultrasound
TVUS  transvaginal ultrasound
VCUG  voiding cystourethrogram
Imaging Modalities

X-Ray Imaging
- x-rays, or Roentgen rays, are a form of electromagnetic energy of short wavelength
- as x-ray photons traverse matter, they can be absorbed (a process known as “attenuation”) and/or scattered
  - the density of a structure determines its ability to attenuate or “weaken” the x-ray beam
  - air < fat < water < bone < metal
- structures that have high attenuation, e.g. bone, appear white on the resulting images

Plain Films
- x-rays pass through the patient and interact with a detection device to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available
- disadvantages: radiation exposure, generally poor at distinguishing soft tissues

Fluoroscopy
- continuous x-rays allow real-time visualization
- used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- on the fluoroscopic image black and white are reversed so that bone and contrast agents appear dark and radiolucent structures appear light

Computed Tomography (CT)
- x-ray beam opposite a detector moves in a continuous 360 degree arc as patient is advanced through the imaging system
  - subsequent computer assisted reconstruction of anatomical structures from the axial plane
  - attenuation is quantified in Hounsfield units:
    - adjusting the “window width” (range of Hounsfield units displayed) and “window level” (midpoint value of the window width) can maximally visualize certain anatomical structures
    - e.g. CT chest can be viewed using “lung”, “soft tissue” and “bone” settings
- contraindications: pregnancy (relative), contraindications to contrast agents (e.g. allergy, renal failure)
- advantages: delineates surrounding soft tissues, excellent at delineating bones and identifying lung/liver masses, may be used to guide biopsies, spiral CT has fast data acquisition, helical CT allows 3D reconstruction, CT angiography is less invasive than conventional angiography
- disadvantages: high radiation exposure, IV contrast injection, anxiety of patient when going through scanner, higher cost and less available than plain film

Ultrasound (U/S)
- high frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or “echo”) occurs when the sound waves pass through tissue interfaces of different acoustic densities
- structures are described based on their echogenicity; hyperechoic structures appear bright whereas hypoechoic structures appear dark
- higher ultrasound frequencies result in greater resolution but greater attenuation (i.e. deeper structures more difficult to visualize)
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (i.e. tissue/air) or absorbs (tissue/bone) sound waves; enhancement refers to the increase in reflection amplitude (increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- Doppler: determines the velocity of blood flowing past the transducer based on the Doppler effect
- Duplex scan: Doppler + visual images
- advantages: relatively low cost, non-invasive, no radiation, real time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), determines cystic versus solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus

**Calculated using average natural background exposure in Canada (Health Canada: http://www.hc-sc.gc.ca/hl-vs/iyh-vsv/environ/expos-eng.php)

## Attenuation
- Bone (= bright) > grey matter > white matter (“fatty” myelin) > CSF > air (= dark)
**Magnetic Resonance Imaging (MRI)**

- Non-invasive technique that does not use ionizing radiation
- Able to produce images in virtually any plane
- Patient is placed in a magnetic field; protons (H+) align themselves along the plane of magnetization due to intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on which deflects all the protons off their aligned axes due to absorption of energy from the radiofrequency beam. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by a computer to generate MR images.
- The MR image reflects the signal intensity picked up by the receiver. This signal intensity is dependent on:
  1. Hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. Magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment (see Table 1)

<table>

<tr>
<th>Imaging Techniques</th>
<th>Contrast Enhancements</th>
<th>Main Application</th>
<th>Advantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffusion Weighted</td>
<td>Contrast dependent on the molecular motion of water. Decreased diffusion is hyperintense (bright), whereas increased diffusion is hypointense (dark)</td>
<td>Neuroradiology</td>
<td>Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies. An acute infarction will appear hyperintense</td>
</tr>
<tr>
<td>T1-Weighted</td>
<td>Fluid is hypointense (dark) and fat is hyperintense (bright)</td>
<td>Body soft tissues</td>
<td>Often considered an anatomic scan since they provide a reference for functional imaging</td>
</tr>
<tr>
<td>T2-Weighted</td>
<td>Fluid is hyperintense (bright) and fat is hypointense (dark)</td>
<td>Body soft tissues</td>
<td>Often considered a pathologic scan since they will highlight edematous areas associated with certain pathologies</td>
</tr>
</tbody>
</table>

**Positron Emission Tomography Scans (PET)**

- Non-invasive technique that involves exposure to ionizing radiation (~7 mSv)
- Nuclear medicine imaging technique that produces images of functional processes in the body
- Current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- Positron-producing radioisotope, such as 18-fluorodeoxyglucose (18-FDG) is chemically incorporated into a metabolically active molecule (glucose), injected into patient, which travels to target organ, accumulates in tissues of interest, and as radioactive substance begins to decay, gamma rays are produced which are detected by PET scanner
- Advantages: shows metabolism and physiology of tissues (not only anatomic), in oncology allows diagnosis, staging, restaging (lung, breast, colorectal, lymphoma, melanoma, esophageal, head and neck), has predictive and prognostic value (breast, lymphoma), can evaluate cardiac viability
- Disadvantages: cost, ionizing radiation
- Contraindications: pregnancy

<tr>
<td>X-ray/CT</td>
<td>1. Barium (oral or rectal)</td>
<td>Radiopaque substance which helps to delineate intraluminal anatomy, may demonstrate patency, lumen integrity, or large filling defects</td>
<td>Risk of nephrotoxicity</td>
<td>Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation</td>
</tr>
<tr>
<td></td>
<td>2. Iodine (IV injection)</td>
<td>Delineates intraluminal anatomy, may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ</td>
<td></td>
<td>Previous adverse reaction to contrast, renal failure, diabetes, pregnancy, multiple myeloma, severe heart failure and dehydration</td>
</tr>
<tr>
<td>MRI</td>
<td>1. Gadolinium-Chelates (IV injection)</td>
<td>Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; gadolinium has some effect on T2-relaxation time; highlights highly vascular structures (i.e. tumours)</td>
<td>Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease</td>
<td>Previous adverse reaction to contrast or if end-stage renal disease (relative contraindication)</td>
</tr>
<tr>
<td>U/S</td>
<td>1. Microbubbles (IV injection)</td>
<td>Since gas is highly echogenic, the microbubbles allow for echo-enhancement of a tissue</td>
<td></td>
<td>Contraindicated in individuals with right-to-left cardiac shunts or people with known hypersensitivity reactions</td>
</tr>
</tbody>
</table>
Chest Imaging

Chest X-Ray (CXR)

Standard Views
- posteroanterior (PA): anterior chest against film plate to minimize magnification of the heart size
  - helps localize lesions when combined with PA view
- lateral: better visualization of retrocardiac space and thoracic spine (more sensitive at picking up pleural effusions)
  - enlarged cardiac silhouette
- anteroposterior (AP): for bedridden patients (generally a lower quality film than PA)
- lateral decubitus: to assess for pleural effusion and pneumothorax in bedridden patients
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

![CXR views](image)

Figure 1. CXR views

Approach to CXR

Basics
- ID: patient name, MRN, sex, age
- date of exam
- markers: Right and/or Left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (6th anterior and 10th posterior ribs should be visible), penetration (thoracic spine should be visible) and rotation (clavicles vs. spinous process)

Analysis
- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- abdomen (see Abdominal Imaging, MI10):
  - free air under the diaphragm, air-fluid levels, distention in small and large bowels
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
  - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels, mediastinum
  - cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem bronchi, and segmental bronchi, lymph nodes
- lungs: lung parenchyma, pleura, diaphragm
  - spine sign: on lateral films, vertebral bodies should appear progressively radiolucent as one moves down the thoracic vertebral column. If they appear more radiopaque, it is an indication of pathology (i.e. consolidation in overlying left lower lobe)
  - comment on abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm

Sodium Bicarbonate plus N-acetylcysteine Prophylaxis: A Meta-analysis

*JACC Cardiovasc Interv* 2009;2:1116-1124

**Study:** A meta-analysis of 10 RCTs.

**Objective:** To compare N-acetylcysteine (NAC) + sodium bicarbonate (NaHCO$_3$) to NAC + normal saline hydration in prevention of acute kidney injury (AKI) from IV contrast.

**Patients:** Those receiving IV contrast for various indications (PCI, angiography, catheterization)

**Results:** Combination treatment of NAC with intravenous NaHCO$_3$, reduced contrast-induced AKI by 35% (relative risk: 0.65; 95% confidence interval: 0.40 to 1.05). However, the combination of N-acetylcysteine plus NaHCO$_3$, did not significantly reduce renal failure requiring dialysis.

**Conclusion:** Combination prophylaxis should be considered for all high-risk patients (emergency cases or patients with chronic kidney disease).
**Anatomy**

**Localizing Lesions**
- silhouette sign: loss of normal interfaces due to lung pathology (consolidation, atelectasis, mass), which can be used to localize disease in specific lung segments (see Table 3)
  - note that pleural or mediastinal disease can also produce the silhouette sign

<table>

Computed Tomography (CT) Chest

Approach to CT Chest
- soft tissue window
  - thyroid, chest wall, pleura
  - heart: chambers, coronary artery calcifications, pericardium
  - vessels: aorta, pulmonary artery, smaller vasculature
  - lymph nodes: mediastinal, axillary
- bone window
  - look at vertebral, sternum, manubrium, ribs for fractures, lytic lesions, sclerosis
- lung window
  - central-trachea: patency, secretions
  - bronchial trees: anatomic variants, mucus plugs, airway collapse
  - lung parenchyma: fissures, nodules, fibrosis/interstitial changes
  - pleural space: effusions

Lung Abnormalities

Atelectasis
- pathogenesis: collapse of alveoli due to restricted breathing, blockage of bronchi, external compression or poor surfactant
- findings:
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis:
  - obstructive (most common): air distal to obstruction is reabsorbed causing alveolar collapse
    - endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury) or mucus plug (cystic fibrosis)
  - compressive:
    - tumour, bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
    - hyaline membrane disease, prematurity
  - passive (relaxation): a result of air or fluid in the pleural space
    - pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (CT thorax) to rule out a bronchogenic carcinoma

Consolidation
- pathogenesis: fluid (water, blood), inflammatory exudates, protein, or tumour in alveoli
- findings:
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign

Figure 4. CT thorax windows

DDx of Airspace Disease
- Pus (e.g. infections such as pneumonia, non-infectious inflammatory process)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchioalveolar carcinoma, lymphoma)
- Protein (e.g. alveolar proteinosis)

Figure 5. Atelectasis: RML collapse
**Pulmonary Nodule**
- **findings**:
  - fluid: pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, bronchiolitis obliterans organizing pneumonia (BOOP), allergic bronchopulmonary aspergillosis (ABPA), aspiration, sarcoidosis
  - protein: pulmonary alveolar proteinosis
  - tumour: bronchoalveolar carcinoma, lymphoma
- **management**: varies depending on the pattern of consolidation, which can suggest different etiologies. Management should also be done in the context of clinical picture

**Interstitial Disease**
- **pathogenesis**: pathological process involving the interlobular connective tissue (i.e. “scaffolding of the lung”)
- **findings**:
  - linear: fine lines caused by thickened connective tissue septae
  - Kerley B: short horizontal lines extending from lateral lung margin
  - Kerley C: diffuse linear pattern throughout lung
  - seen in pulmonary edema, lymphangitic carcinomatosis and atypical interstitial pneumonias
  - nodular: 1-5 mm well-defined nodules distributed evenly throughout lung
  - seen in malignancy, pneumoconiosis and granulomatous disease (sarcoidosis, miliary TB)
  - reticular (honeycomb): parenchyma replaced by thin-walled cysts suggesting extensive destruction of pulmonary tissue and fibrosis (see Figures 7 and 8)
  - seen in interstitial pulmonary fibrosis (IPF), asbestosis and CVD
  - NOTE: watch for pneumothorax as a complication
  - reticulonodular: combination of reticular and nodular patterns
  - may also see signs of airspace disease (atelectasis and consolidation)
- **differential diagnosis**:
  - occupational/environmental exposure
  - inorganic: asbestosis, coal miner’s pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
  - organic: hypersensitivity pneumonitis, bird fancier’s lung, farmer’s lung (moldy hay), and other organic dust
  - autoimmune: CVD (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IBD, celiac disease, vasculitis
  - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), heroin, cocaine, methadone
  - infections: non-tuberculous mycobacteria, certain fungal infections
  - idiopathic: hypersensitivity pneumonitis, IPF, BOOP
- **for Causes of Interstitial Lung Disease Classified by Distribution**, see Respirology, R12
- **management**: high resolution CT thorax and biopsy

**Pulmonary Nodule** (see Table 5)
- **findings**: round opacity ± silhouette sign
- **note**: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
- **differential diagnosis**:
  - extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
  - solitary nodule:
    - tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
    - inflammation: histioplasmosis, tuberculosis, coccidiodomycosis
  - vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
  - multiple nodules: metastases, abscess, granulomatous lung disease [TB, fungal, sarcoid, rheumatoid nodules, silicosis, granulomatosis with polyangiitis (GPA)]
- **management**: clinical information and CT appearance determine level of suspicion of malignancy
  - if high probability of malignancy, invasive testing (fine needle aspiration, transbronchial/ transthoracic biopsy) is indicated
  - if low probability of malignancy, repeat CXR or CT in 1-3 mo and then every 6 mo for 2 yr; if no change, then >99% chance benign

**DDx for Cavitating Lung Nodule**
- **WEIRD HOLES**
  - GPA (Wegener’s)
  - Embolic (pulmonary, septic)
  - Infection (anaerobes, pneumocystis, TB)
  - Rheumatoid (neurobiotic nodules)
  - Developmental cysts (sequestration)
  - Histiocytosis
  - Oncological
  - Lymphangioleiomyomatosis
  - Environmental, occupational
  - Sarcoïdosis

**DDx of Interstitial Lung Disease**
- **FASSTEN** (upper lung disease)
  - Farmer’s lung (hypersensitivity pneumonitis)
  - Ankylosing spondylitis
  - Sarcoidosis
  - Silicosis
  - TB
  - Eosinophilic granuloma (Langerhans cell histiocytosis)
  - Neurofibromatosis
- **BAD RASH** (lower lung disease)
  - Bronchiolitis obliterans with organizing pneumonia (BOOP)
  - Asbestos
  - Drugs (nitrofurantoin, hydroxyzine, INH, amiodarone, many chemo drugs)
  - Rheumatological disease
  - Aspiration
  - Scleroderma
  - Hamman Rich (interstitial pulmonary fibrosis) and idiopathic pulmonary fibrosis

**Figure 6. Consolidation: bacterial pneumonia**

**Figure 7. Interstitial disease: fine reticular pattern**

Pulmonary Edema
- **Pathogenesis:** fluid accumulation in the airspaces of the lungs
- **Findings:**
  - Vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
  - Fluid initially collects in interstitium:
    - Loss of definition of pulmonary vasculature
    - Peribronchial cuffing
    - Kerley B lines
    - Reticulonodular pattern
    - Thickening of interlobar fissures
  - As pulmonary edema progresses, fluid begins to collect in alveoli causing diffuse air space disease often in a “bat wing” or “butterfly” pattern in perihilar regions with tendency to spare the outermost lung fields
- **Differential diagnosis:** cardiogenic (CHF), renal failure, volume overload, non-cardiogenic (ARDS)

Pulmonary Embolism
- **Pathogenesis:** arterial blockage in the lungs
- **Findings:** Westermark sign (localized pulmonary oligemia), Hampton’s hump (triangular peripheral infarct), enlarged RV and RA, atelectasis, pleural effusion, and rarely pulmonary edema
- **Management:** V/Q scan, CT angiography (look for filling defect)

Pleural Abnormalities

Pleural Effusion
- **Pathogenesis:** gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
- **Findings:**
  - Upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
  - More obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  - More difficult to detect on supine film; look for the “deep (costophrenic) sulcus” sign, “double diaphragm” sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  - Mediastinal shift may occur if air is under tension (i.e. tension pneumothorax)

Pneumothorax
- **Pathogenesis:** gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
- **Findings:**
  - Upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
  - More obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  - More difficult to detect on supine film; look for the “deep (costophrenic) sulcus” sign, “double diaphragm” sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  - Mediastinal shift may occur if air is under tension (i.e. tension pneumothorax)
• differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, CVP line insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
• management: needle decompression or chest tube insertion, repeat CXR to ensure resolution

Asbestos
• asbestos exposure may cause various pleural abnormalities including benign plaques (most common) that may calcify, diffuse pleural fibrosis, effusion, and malignant mesothelioma

**Mediastinal Abnormalities**

**Mediastinal Mass**
• the mediastinum is divided into three compartments; this provides the approach to the differential diagnosis of a mediastinal mass
• anterior (anterior border formed by anterior trachea and posterior border by the heart and great vessels)
  - 4 Ts: see sidebar
  - cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
• middle (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
  - esophageal carcinoma, esophageal duplication cyst
  - metastatic disease
  - lymphadenopathy (all causes)
  - hiatus hernia
  - bronchogenic cyst
• posterior (posterior to the middle line described above)
  - neurogenic tumour (e.g. neurofibroma, schwannoma)
  - multiple myeloma
  - pheochromocytoma
  - neurenteric cyst
  - thoracic duct cyst
  - lateral meningocele
  - Bochdalek hernia
  - extramedullary hematopoiesis
• in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, and hematoma

**Enlarged Cardiac Silhouette**
• heart borders
  - on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  - on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
• cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
  - using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
  - differential of ratio >0.5
    - cardiomegaly (myocardial dilatation or hypertrophy)
    - pericardial effusion
    - poor inspiratory effort/low lung volumes
    - pectus excavatum
  - ratio <0.5 does not exclude enlargement (e.g. cardiomegaly + concomitant hyperinflation)
• pericardial effusion
• globular heart with loss of indentations on left mediastinal border
• right atrial enlargement
  - increase in curvature of right heart border and enlargement of SVC
• left atrial enlargement
  - straightening of left heart border
  - increased opacity of lower right side of cardiovascular shadow (double heart border)
  - elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and “double” heart border >7 cm, splayed carina (late sign)
• right ventricular enlargement
  - elevation of cardiac apex from diaphragm
  - anterior enlargement leading to loss of retrosternal air space on lateral
  - increased contact of RV against sternum
• left ventricular enlargement
  - displacement of cardiac apex inferiorly and posteriorly – “boot-shaped” heart
Tubes, Lines, and Catheters

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

Central Venous Catheter
- used for fluid and medication administration, vascular access for hemodialysis, and central venous pressure (CVP) monitoring
- tip must be located distal to (above) right atrium to prevent inducing arrhythmias or perforating wall of atrium
  - if monitoring CVP, catheter tip must be proximal to venous valves
- tip of well positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle and inferiorly by top of RA
- course should parallel course of SVC – if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

Endotracheal Tube
- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 4 cm above tracheal carina – avoids bronchus intubation and vocal cord irritation
- maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture – ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

Nasogastric Tube (NG Tube)
- tip and sideport of NG tube should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), intracranial perforation (trauma patients), pneumothorax

Swan-Ganz Catheter
- to monitor pulmonary capillary wedge pressure and to measure cardiac output for suspected left ventricular dysfunction
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

Chest Tube
- in dorsal and caudal portion of pleural space to evacuate fluid usually
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: lung perforation (mediastinal opacities)

Abdominal Imaging

Abdominal X-Ray (AXR)

- indications:
  - acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction (SBO), large bowel obstruction (LBO)
  - chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
  - not useful in: GI bleeds, chronic anemia, vague GI symptoms
- AXR 3 most common views: left lateral decubitus (LLD), supine, erect upright
Anatomy

- abdomen divided into 2 cavities:
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

Approach to Abdominal X-Ray (AXR)

- mnemonic: “Free ABDO”
- Free = free fluid
  - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
  - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
  - ascites and blood (hemoperitoneum) are the same density on the radiograph and therefore cannot be differentiated
- A = air
  - volvulus – twisting of the bowel upon itself; from most to least common:
    - sigmoid: “coffee bean” sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal large bowel dilation
    - cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
    - gastric: rare
    - small bowel: “corkscrew sign” (rarely diagnosed on plain films, seen best on CT)
- toxic megacolon
  - manifestation of fulminant colitis
  - extreme dilatation of colon (>6.5 cm) with mucosal changes including foci of edema, ulceration and pseudopolyps, loss of normal haustral pattern
- B = bowel wall thickening
  - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall (“thumb-printing”), or a picket-fence appearance of the valvulae conniventes (“stacked coin” appearance)
  - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
- D = densities
  - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
  - abnormal calcifications: approach by location
    - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
    - RLQ: ureteral stone, appendicolith, gallstone ileus
    - LUQ: renal stone, adrenal calcification, tail of pancreas
    - LLQ: ureteral stone
    - central: aorta/aortic aneurysm, pancreas, lymph nodes
    - pelvis: phleboliths (calcified veins), uterine fibroids, bladder stones
- O = organs
  - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
  - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

Abdominal CT
- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast:
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
  - portal venous phase: indicated for majority of cases
  - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
  - oral contrast: barium or water soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
  - rectal contrast: given for investigation of colonic lesions
- caution: contrast allergy (may premedicate with steroids and antihistamine)
- contraindication: impaired renal function, based on eGFR
**Approach to Abdominal Computed Tomography (CT)**

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ/structure individually, from top to bottom evaluating size and shape of each area of increased or decreased density
- evaluate the following
  - soft tissue window
    - liver, gallbladder, spleen and pancreas
    - adrenals, kidneys, ureters and bladder
    - stomach, duodenum, small bowel mesentery and colon/appendix
    - retroperitoneum: aorta, vena cava and mesenteric vessels; look for adenopathy in vicinity of vessels
    - peritoneal cavity for fluid or masses
    - abdominal wall and adjacent soft tissue
  - lung window
    - visible lung (bases)
  - bone window
    - vertebræ, spinal cord, and bony pelvis

**CT and Bowel Obstruction**

- cause of bowel obstruction rarely found on plain films – CT is best choice for imaging
- the “3,6,9” rule is a very useful guide to determining when the bowel is dilated. The maximum diameter of the bowel is 3 cm for small bowel, 6 cm for large bowel and 9 cm for cecum. This can also be useful in distinguishing between small and large bowel and when assessing for ‘impending’ cecal perforation (post-untreated Ogilvie’s syndrome)

**CT Colonography (virtual colonoscopy)**

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon in order to look for masses
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, staging of obstructing colonic lesions

**Contrast Studies**

Specific Visceral Organ Imaging

Liver
- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MR: also excellent in evaluation of primary liver tumours, liver metastases, and other parenchymal conditions. It is particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- findings:
  - altered liver size, contour, density
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - portal hypertension: increased portal vein diameter, collateral veins, splenomegaly (≥12 cm), portal vein thrombosis, recanalization of the umbilical vein
  - varices (caput medusa, esophageal varices, porto-systemic shunts, dilated splenic vein)
  - splenomegaly and ascites
- U/S: cirrhosis appears nodular and hypechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
- CT: fatty infiltration appears hypodense
- investigation of liver masses
- require contrast to visualize certain hepatic masses

</tbody>
</table>

Spleen
- U/S, CT, and/or nuclear medicine scan
- CT for splenic trauma (hemorrhage)

Biliary Tree
- U/S
  - bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT
  - dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- ERCP, MRCP, PTC: further evaluation of obstruction and possible intervention

Figure 15. ERCP: biliary tree

Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease
Arch Intern Med 1999;159:2573-2581
Purpose: To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including ultrasonography, oral cholecystography, radionucleotide scanning with Technetium, MRI, CT.
Study Characteristics: Meta-analysis of 30 studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease.
Participants: No limits.
Main Outcomes: Sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 mo clinical follow-up for cholelithiasis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.
Results: For evaluating cholelithiasis, U/S had the best unadjusted sensitivity (0.97; 95% CI, 0.95 to 0.99) and specificity (0.96, 95% CI, 0.93 to 0.98), and adjusted (for verification bias) sensitivity (0.84, 95% CI, 0.76 to 0.92) and specificity (0.90; 95% CI, 0.90 to 1.00). For evaluating acute cholecystitis, radionucleotide scanning has the best sensitivity (0.97; 95% CI, 0.96 to 0.98) and specificity (0.90; 95% CI, 0.86 to 0.95).
Conclusions: U/S is the test of choice for diagnosing cholelithiasis and radionucleotide scanning is the superior test for diagnosing acute cholecystitis.

Liver Mass DDx
- 5 hs
  - HCC
  - Hydatid cyst
  - Hemangioma
  - Hepatic adenoma
  - Hyperplasia (focal nodular)
Pancreas
- tumours
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
  - MRCP: imaging of ductal system using MRI cholangiography
  - ERCP: endoscope to inject dye into the biliary tree and X-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval); acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures
- pancreatitis and/or its complications: pseudocyst, abscess, necrosis, splenic artery aneurysm (see “itis” Imaging below)

“itis” Imaging

Acute Cholecystitis
- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or, in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see General Surgery, GS46)
- best imaging modality: U/S (best sensitivity and specificity), nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: thick wall, pericholecystic fluid, gallstones, dilated gallbladder, positive sonographic Murphy’s sign
- management: cholecystectomy

Acute Appendicitis
- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see General Surgery, GS28)
- best imaging modality: U/S or CT
- findings:
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible
  - U/S may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: appendectomy

Acute Diverticulitis
- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro or macroscopic perforation (see General Surgery, GS31)
- best imaging modality: CT is modality of choice, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel
- findings:
  - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - sometimes difficult to distinguish from perforated cancer (therefore send abscess fluid for cytology and follow up with colonoscopy)
  - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: appendectomy
draining...
Chronic Pancreatitis
- pathogenesis: (see Gastroenterology, G46)
- best imaging modality: MRCP
- findings: U/S, CT scan and MRI may show calcifications, ductal dilatation, enlargement of the pancreas and fluid collections (e.g. pseudocysts) adjacent to the gland. However, magnetic resonance cholangiopancreatography (MRCP) is becoming the diagnostic test of choice since it can show calcification and pancreatic duct obstruction.

Angiography of GI Tract
- anatomy of the GI tract arterial blood supply branches
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery (SMA): jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery (IMA): left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
  - flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: non-invasive using IV contrast (no catheterization required)

Genitourinary System and Adrenal

Urological Imaging
KUB (kidneys, ureters, bladder)
- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radio-opaque renal stones (all stones but uric acid and indinavir), as well as indwelling ureteric stents or catheters
- findings: addition of intravenous contrast excreted by the kidney (intravenous urogram) allows greater visualization of the urinary tract, but has been largely replaced by CT urography

Abdominal CT
Renal Masses
- Bozniak classification for cystic renal masses
  - classes I-II are benign and can be disregarded
  - class IIF should be followed
  - classes III-IV are suspicious for malignancy, requiring additional workup

Table 13. Bozniak Classification for Cystic Renal Masses

<table>
<thead>
<tr>
<th>Classes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simple renal cysts</td>
<td></td>
</tr>
<tr>
<td>Class I</td>
<td>Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hair thin wall</td>
</tr>
<tr>
<td>Class II</td>
<td>Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (&lt;3 cm) that do not enhance with contrast</td>
</tr>
<tr>
<td>Complex renal cysts</td>
<td></td>
</tr>
<tr>
<td>Class III</td>
<td>Thick irregular walls, ± calcifications, ± septated, enhancing walls or septa with contrast</td>
</tr>
<tr>
<td>Renal cell carcinoma</td>
<td></td>
</tr>
<tr>
<td>Class IV</td>
<td>Same as class III + soft tissue enhancement with contrast (defined as &gt;10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase ± areas of necrosis</td>
</tr>
</tbody>
</table>

- plain CT
  - indications: general imaging of renal anatomy, although specific study types have supplanted plain CT for many indications, including CT urography (upper tract uroepithelial malignancies and renal calculi) and triphasic CT (renal masses)
- CT urography
  - indications: excretory phase imaging allows detailed assessment of urinary tracts, high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, useful for assessment of renal calculi
- triphasic CT
  - indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins and better characterization of suspicious renal masses, with particular utility in differentiating renal cell carcinoma from more benign masses
  - phases: unenhanced, nephrographic, and excretory

Imaging Modality Based on Presentation
- Acute testicular pain = Doppler, U/S
- Amenorrhea = U/S, MRI (brain)
- Bloating = U/S, CT
- Flank pain = U/S, CT
- Hematuria = U/S, Cystoscopy, CT
- Infertility = Hysterosalpingogram, MRI
- Lower abdominal mass = U/S, CT
- Lower abdominal pain = U/S, CT
- Renal colic = U/S, KUB, CT
- Testicular mass = U/S
- Urethral stricture = Urethrogram

Figure 18. Triphasic CT of an angiomyolipoma: showing fat density with non-contrast scan, mildly enhancing with contrast

Figure 19. Triphasic CT of a renal cell carcinoma: showing arterial enhancing right renal lesion with venous washout (shunting)
U/S
- indications: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic renal masses vs. complicated cysts); technique of choice for screening patients with suspected hydronephrosis (no intravenous contrast injection, no radiation to patient, and can be used in patients with renal failure); transrectal U/S (TRUS) useful to evaluate prostate gland and guide biopsies; doppler U/S to assess renal vasculature
- findings: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular-wall

Retrograde Pyelography
- indications: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction)
- findings: only yields information about the collecting systems (renal pelvis and associated structures)
  - no information regarding the parenchyma of the kidney

Voiding Cystourethrogram (VCUG)
- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time) to visualize bladder
- indications: children with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction or vesicoureteral reflux
- findings: contractility and evidence of vesicoureteric reflux

Retrograde Urethrogram
- a small Foley catheter placed into penile urethral opening
- indications: used mainly to study strictures or trauma to the male urethra (Figure 20)

MRI
- advantages: high spatial and tissue resolution, lack of exposure to ionizing radiation and nephrotoxic contrast agents
- indications: indicated over CT for depiction of renal masses in patients with previous nephron sparing surgery, patients requiring serial follow-ups (less radiation dosage), patients with reduced renal function, and patients with solitary kidneys

Renal Nuclear Scan

<table>
<thead>
<tr>
<th>Type of Test</th>

<td>Assess renal anatomy: investigation of pyelonephritis and cortical scars</td>
<td>$^{99m}$Tc-DMSA, $^{99m}$Tc-glucicollidate</td>
</tr>
</tbody>
</table>

Gynecological Imaging

U/S
- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air containing loops of bowel
  - indication: good initial investigation for suspected pelvic pathology
- transvaginal approach provides enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves at reduced distances
  - indication: improved assessment of ovaries, first trimester development, and ectopic pregnancies

Hysterosalpingogram
- indications: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)
- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent

CT/MRI
- indications: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynecological malignancies

Pregnancy should always be ruled out by β-HCG before CT of a female pelvis (or any organ system) is performed.
Sonohysterogram
- saline infusion sonohysterogram involves instilling fluid into the uterine cavity transcervically to provide enhanced endometrial visualization during transvaginal ultrasound examination.
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on transvaginal sonography (i.e. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

<table>
<thead>
<tr>
<th>Finding</th>
<th>Typical</th>
<th>Atypical Features</th>

### Neuroradiology

**Modalities**
- CT is the modality of choice for most neuropathology; even under circumstances when MRI is preferred, CT is frequently the initial study because of its speed, availability and lower cost
- CT is preferred for
  - acute head trauma: CT is best for visualizing “bone and blood”; MRI is used in this setting only when CT fails to detect an abnormality in the presence of strong clinical suspicion
  - acute stroke: MRI ideal, CT most frequently used
  - suspected subarachnoid or intracranial hemorrhage
  - meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
  - tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumours, respectively

**DDx for Ring Enhancing Lesion on CT with Contrast**
- MAGICAL DR
  - Metastases
  - Abscess
  - Glioblastoma (high grade astrocytoma)
  - Infarct
  - Contusion
  - AIDs
  - Lymphoma
  - Demyelination
  - Resolving hematoma

[*the 3 most common Dx’s*]
Skull Films
- rarely performed as CT is the modality of choice
- indications: include screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, post-operative changes and confirmation of hardware placement, skeletal surveys
- generally not indicated for non-penetrating head trauma

CT
- excellent study for evaluation of bony abnormalities
- often done first without and then with intravenous contrast to show vascular structures or anomalies
- vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or white/show enhancement) with contrast injection
  - when in doubt, look for circle of Willis or confluence of sinuses to determine presence of contrast enhancement
- posterior fossa can be obscured by extensive bony artifact
- rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space occupying lesion, hydrocephalus, and cerebral edema
- multiplanar imaging can be performed with newer generation of multidetector CT scanners

Myelography
- introduction of water-soluble, low-osmotic-contrast media into subarachnoid space using lumbar puncture followed by x-ray or CT scan
- indications: excellent study for disc herniations, traumatic nerve root avulsions, patients with contraindication to MRI

MRI
- indications: shows brain and spinal soft tissue anatomy in fine detail, clearly distinguishes white from grey matter (especially T1-weighted series), multiplanar reconstruction helpful in pre-op assessment

Cerebral Angiography/CT Angiography/MR Angiography
- indications: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissection
- conventional digital subtraction angiography (DSA) remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation has risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MR angiography (MRA) methods (phase contrast, time of flight, gadolinium-enhanced) and CT angiography (CTA) are much less invasive without actual risk to intracranial or neck vessels
- MRA and CTA are often used first as ‘screening tests’ for the assessment of subarachnoid hemorrhage, vasospasm, aneurysms

Table 17. Two Types of Hydrocephalus

<table>
<thead>
<tr>
<th>Type</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Communicating/extra-ventricular</td>
<td>Obstruction distal to the ventricles e.g. at the level of the arachnoid granulations; imaging shows all ventricles dilated</td>
</tr>
<tr>
<td>Non-communicating</td>
<td>Obstruction within the ventricular system e.g. mass obstructing the aqueduct or foramen of Monro; imaging shows dilatation of ventricles proximal to the lesion</td>
</tr>
</tbody>
</table>

Nuclear Medicine
- SPECT using $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) imaging assesses cerebral blood flow by diffusing rapidly across the blood brain barrier and becoming trapped within cells
- $^{18}$FDG PET imaging assesses cerebral metabolic activity
Approach to CT Head

- think anatomically, work from superficial to deep
- scan: confirm that the imaging is of the correct patient, whether contrast was used, if the patient is aligned properly, if there is artifact present
- skin/soft tissue: examine the soft-tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also investigate: ear, orbital contents (globe, fat, muscles), parotid, muscles of mastication (masseter, temporalis, pterygoids), visualized pharynx
- bone and airspace (use the bone window): check calvarium, visualized mandible, visualized C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumour, or fracture
- dura and subdural space: look for crescent-shaped hyperdensity in the subdural space as evidence of subdural hematoma; look for a lentiform hyperdensity in epidural space as evidence of epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: look for symmetry of the parenchyma for evidence of midline shift; look for poor contrast between grey and white matter as evidence of possible infarction, tumour, edema, infection, or contusion; look for hyperdensities in the parenchyma suggestive of enhancing lesions, intracerebral hemorrhage, or calcification; central grey matter nuclei should be visible, including globus pallidus, putamen, and internal capsule, otherwise suspect infarct, tumour, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; look for hyperdensities in the ventricles indicative of ventricular/subdural hemorrhage; look at ventricular size for evidence of hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood
- dura/subdural hemosiderin: check for hyperdensity in the subdural space as evidence of subdural hematoma
- C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; bone and airspace (use the bone window): check calvarium, visualized mandible, visualized C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumour, or fracture

Selected Pathology

- see Neurosurgery, NS4-23 for intracranial mass lesions
- see Neurosurgery, NS30-35 and Plastic Surgery, PL28 for head trauma
- see Emergency Medicine, ER7 for vertebral trauma
- see Neurosurgery, NS24-29 and Orthopedics, OR21 for degenerative spinal abnormalities

Cerebrovascular Disease (see Neurology, N43-46 and Neurosurgery, NS18-23)

- pathogenesis of stroke: see Neurology, N43
- best imaging modality ischemic strokes usually cause infarcts which can be detected by both CT and MR
- findings of infarction:
  - early changes
    - CT
      - usually normal within 6 h of infarction
      - edema (loss of grey-white matter differentiation – “insular ribbon” sign, effacement of sulci, mass effect)
      - within 24 h, development of low-density, wedge-shaped area of infarction extending to periphery (correlating to vascular territory distal to affected artery)
      - refer to Functional Neuroanatomy software online (www.torontonotes.ca)
      - in case of ischemic stroke, may see hyperattenuating (bright) artery (hyperdense MCA sign) representing intravascular thrombus or embolus
      - in case of hemorrhagic stroke or transformation (common in basal ganglia and cortex), may see bright acute blood surrounded by edema
    - MRI
      - edema with high signal on T2-weighted images and FLAIR image (loss of grey-white matter differentiation, effacement of sulci, mass effect)
      - diffusion-weighted image (DWI) shows acute high signal changes demonstrating restricted movement of water indicative of cytotoxic edema. DWI usually indicates stroke damage before CT
      - apparent diffusion coefficient (ADC) image shows low signal intensity in acute ischemia (nadir 3-5 d, returns to baseline 1-4 wk)
  - subacute changes on CT and MRI
    - edema and mass effect more prominent
    - gyral enhancement with contrast indicative of blood-brain barrier breakdown
  - chronic changes on CT and MRI
    - encephalomalacia (parenchymal volume loss) with dilatation of adjacent ventricles

Diffusion-weighted Imaging (DWI) and Apparent Diffusion Coefficient (ADC) imaging

- diffusion-weighted imaging (DWI) shows acute high signal changes demonstrating restricted movement of water indicative of cytotoxic edema. DWI usually indicates stroke damage before CT
- apparent diffusion coefficient (ADC) image shows low signal intensity in acute ischemia (nadir 3-5 d, returns to baseline 1-4 wk)

Neural Imaging

- Symptom of stroke
  - Non-contrast CT
    - Hemorrhage absent
  - To detect infarct, MR scan with diffusion-weighted sequence OR a CTA

Early Signs of Brain Infarction at CT: Observer Reliability and Outcome after Thrombolytic Treatment – Systematic Review

Radiology 2005;235:444-453

Study: Systematic review of 15 studies between 1980-2001 that investigated inter-observer agreement of early CT signs of acute ischemic stroke, and prognostic value of early CT signs in patient outcome. There was a median of 30 CTs and 6 raters per study.

Patients: 3468 adult patients who underwent CT within 6 h of stroke.

Main Outcome: Degree of inter-observer agreement between stroke signs on CT, and risk of death or dependency (using validated stroke scales) based on CT signs used after 1-3 mo.

Results: Prevalence of all early infarction signs was 61%, and interobserver agreement was 0.14-0.78 (k statistic) for any early infarct sign.

Average sensitivity of detecting early ischemic stroke was 66% (range 20%-87%) and average specificity was 87% (range 56%-100%). Experience improved detection, but knowledge of patient history did not. An increased risk of poor outcome (death or dependency) was associated with any early infarction sign, with an odds ratio of 3.11 (95%CI, 2.71-4.48).

Conclusion: Further work is required to determine which signs are most reliably detected and whether any early infarction sign should influence decisions concerning thrombolysis.

Figure 29. CT images of early infarct: (A) absence of left insular ribbon (B) hyperdense artery
• carotid artery disease
  ▪ best imaging modality: Duplex Doppler U/S
  ▪ other modalities: MR angiography or CT angiography if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)

Multiple Sclerosis (MS) (refer to Neurology, N46)
• best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
• findings:
  ▪ characteristic lesion on MRI is cerebral or spinal plaque
  ▪ plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum), centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
  ▪ “Dawson's fingers” refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  ▪ plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
  ▪ conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and magnetic resonance spectroscopy) can be of use
  ▪ perivascular and interstitial edema may be prominent
• acute vs. chronic
  ▪ acute lesions: larger, ill-defined margins and become smaller with sharper margins with resolution of edema and inflammation present at time of acute plaque formation
  ▪ gadolinium enhancing lesions on T1-weighted MRI: accumulation of gadolinium in plaques is associated with new or newly active plaques and with pathologically confirmed acute inflammation in MS; gadolinium enhancement is transient and can persist up to 8 wk in acute plaques (persistence of enhancement should caution against diagnosis of MS)
  ▪ enhancement patterns: concentric ring-enhancing lesions with central contrast pallor arise in previously damaged areas or areas of accelerated local inflammation; ring-enhancing lesions weakly predict the development of persisting hypointense lesions on T1 MRI and are thought to be related to accelerated disease activity and extensive tissue damage, marking inflammation associated with aggressive disease
  ▪ most MS lesions are isointense to white matter on T1-weighted MRI, some are hypointense or “black holes” (especially in the supratentorial region). Nearly half of black holes revert to normal in a few months, presumably due to remyelination and resolution of edema. Persistent black holes may be markers of severe demyelination and axonal loss
  ▪ spinal cord lesions typical of MS:
    ▪ little or no cord swelling
    ▪ unequivocal hyperintensity on T2-weighted sequences
    ▪ size at least 3 mm but less than 2 vertebral segments in length
    ▪ occupy only part of the cord in cross-section
    ▪ focal (i.e. clearly delineated and circumscribed on T2-weighted sequences)

CNS Infections
• leptomeningitis
  ▪ pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood brain barrier (choroid plexus or circumventricular organs)
  ▪ pathogens include: S. pneumoniae, H. influenza, N. meningitidis, L. monocytogenes
  ▪ best imaging modality: best visualized with MRI (T2-weighted/FLAIR) over CT
  ▪ findings:
    ▪ meningeal enhancement (following the gyri/sulci, and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
    ▪ a normal MRI does not rule out leptomeningitis

• herpes simplex encephalitis (see Infectious Diseases, ID20)
  ▪ pathogenesis: inflammation of the brain parenchyma secondary to HSV infection, asymmetrically affects the limbic regions of the brain – temporal lobes, orbitofrontal region, insula, and cingulate gyrus
  ▪ best imaging modality: best imaged with MRI (T1- and T2-weighted imaging)
  ▪ findings:
    ▪ acute (within 4-5 d): high intensity lesions on T2 MRI in temporal and inferior frontal lobes, asymmetric
    ▪ strongly suggestive of HSV encephalitis
    ▪ DDx: infarct, tumour, status epilepticus, limbic encephalitis
    ▪ CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
    ▪ long term may show parenchymal loss to affected areas
cerebritis/cerebral abscess
- Pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the middle cerebral artery
- Pathogens include: S. aureus (often in IVDU, nosocomial), GN bacteria, Streptococcus, Bacteroides
- Best imaging modality: MRI including diffusion (DWI) imaging series – an abscess will be DWI positive; CT is still used as a viable alternative but overall MRI > CT
- Findings according to one of four stages of abscess formation:
  - Early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
  - Late cerebritis (4-9 d): ring enhancement may be present
  - Early capsule (10-13 d): ring enhancement
  - Late capsule (14 d or greater): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperdensity on T2

Musculoskeletal System (MSK)

Modalities

Plain Film/X-Ray
- Usually initial study used in evaluation of bone and joint disorders
- Indications: fractures and dislocations, arthritis, assessment of malalignment, assessment of orthopedic hardware, initial assessment of bone tumors
- Minimum of two films orthogonal to each other (usually AP and lateral) to rule out a fracture
- Image proximal and distal joints (particularly important with paired bones, e.g. radius/ulna)
- Not very effective in evaluating soft tissue injury
- Advantages: fast, inexpensive, readily available, reproducible

CT
- Evaluation of fine bony detail
- Indications: assessment of complex, comminuted, intra-articular or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- Evaluation of soft tissue calcification/ossification
- Advantages: fast, reproducible, excellent bone evaluation, and spatial resolution
- Disadvantages: radiation dose, relatively poor soft tissue characterization in comparison with U/S and MRI

MRI
- Indications: evaluation of internal derangement of joints (ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses
- Advantages: excellent soft tissue contrast, multiplanar imaging, no radiation
- Disadvantages: long imaging times, expensive, claustrophobia, contraindications (e.g. pacemakers, orbital metallic bodies), artifact around metal hardware

Ultrasound
- Indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, ultrasound guided biopsy and injections
- Doppler determines vascularity of structures
- Advantages: good soft tissue evaluation, easy contralateral comparison, dynamic imaging
- Disadvantages: operator dependent, poor for bone evaluation

Nuclear Medicine (Bone Scintigraphy)
- Determine the location and extent of bony lesions
- 99mTc-methylene diphosphonate (MDP) localize to areas of increased bone turnover or calcification – growth plate in children, tumours, infections, fractures, metabolic bone disease (e.g. Paget’s), sites of reactive bone formation, and periostitis
- Very sensitive, not specific (trauma, infection, inflammation look similar)

Approach to interpretation of bone X-Rays
- Identification: name, MRN, age of patient, type of study, region of investigation
- Soft tissues: swelling, calcification/ossification
- Joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- Bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions (Figure 34)
Trauma

Fracture/Dislocation
- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see Orthopedics, OR5

Arthritis

Radiographic Hallmarks of OA
- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

Radiographic Hallmarks of RA
- joint space narrowing – typically uniform
- soft tissue swelling
- erosions
- periarticular osteopenia

Bone Tumour

Approach
- metastatic tumours to bone are much more common than primary bone tumours, particularly if age >40 yr
- diagnosis usually requires a biopsy if primary not located
- few benign tumours/lesions have potential for malignant transformation
- MRI is good for tissue delineation and preoperative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
- plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

Considerations and Tumour Characteristics
- age – most common tumours by age group
  - <1 yr of age: metastatic neuroblastoma
  - 1-20 yr of age: Ewing's tumour in tubular bones
  - 10-30 yr of age: osteosarcoma and Ewing's tumour in flat bones
  - >40 yr of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
  - epiphysis: giant cell tumour, chondroblastoma, geode, eosinophilic granuloma, infection
  - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chondromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
  - diaphysis: fibrous dysplasia, aneurysmal bone cyst, brown tumours, eosinophilic granuloma, Ewing's sarcoma
- expansile
  - aneurysmal bone cyst, giant cell tumour, enchondromas, brown tumours, metastases (especially renal and thyroid), plasmacytoma
- matrix mineralization
  - chondroid (popcorn calcification) or osseous
- margin/zone of transition: area between lesion and normal bone
- cortex: intact, disturbed
- periosteal reaction
- soft tissue mass
- see Figure 34 and Table 18

Types of Fractures
- Transverse
- Oblique
- Spiral

Types of Displacements
- Translation
- Angulation
- Rotation

Figure 33. X-ray of first carpometacarpal joint: normal image (left side) and osteoarthritis (right side) with joint space narrowing and subchondral sclerosis

Benign Lesions which may have Aggressive Features
- Osteomyelitis
- Osteoblastoma
- Aneurysmal bone cyst
- Langerhans cell histiocytosis
- Myositis ossificans

Periosteal Reaction
- "Onion skinning" = Ewing's sarcoma
- "Sunburst", "hair on end" = osteosarcoma
- "Codman's triangle" = osteosarcoma, Ewing's sarcoma, subperiosteal abscess

Lytic = decreased density
Sclerotic = increased density

Margination of lesions
- Punch out
- Thin rim of sclerosis
- Thick rim of sclerosis

Patterns of cortical disturbance
- Expansile
- Endosteal scalloping
- Invisible margin
- Saucerization

Patterns of medullary destruction
- Permeative
- Moth-eaten
- Solid undulating

Periosteal new bone formation
- Onion-skin layered
- Codman's Triangle
- Hair-on-end spiculated
- Sunburst divergent
- Solid undulating

Figure 34. Radiographic appearance of bone remodelling and destruction processes
### Metabolic Bone Disease

#### Osteoporosis
- Reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- Dual energy x-ray absorptiometry (DEXA): gold standard for measuring bone mineral density
  - T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - Osteopenia: \(-2.5 < \text{T-score} < -1\)
    - Osteoporosis: \(\text{T-score} \leq -2.5\)
  - Z-score: the number of standard deviations from the age-matched mean
  - Risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy

#### Infection

**Osteomyelitis**
- MRI is the imaging modality of choice for demonstrating bone, bone marrow, and soft tissue abnormalities
- \(^{99}\text{Tc}\), followed by \(^{111}\text{In}\) labeled white cell scan or gallium radioisotope scan
- Plain film
  - Visible 8-10 d after process has begun
  - Osteomyelitic changes on plain film
    - Soft tissue swelling
    - Local periosteal reaction
    - Pockets of air (from anaerobes) may be seen in the tissues, may also suggest necrotizing fasciitis
    - Mottled and nonhomogeneous with a classic “moth-eaten” appearance
    - Cortical destruction

**Bone Abscess**
- Overlying cortex has periosteal new bone formation
- Sharply outlined radiolucent area with variable thickness in zone of transition
- Variable thickness periosteal sclerosis
- Sequestrum: a piece of dead bone within a Brodie's abscess
- A sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone

#### Metastatic Bone Tumours
- All malignancies have potential to metastasize to bone
- Metastases are 20-30x more common than primary bone tumours
- Metastasis can cause a lytic or a sclerotic reaction when seeding to bone
- When a primary malignancy is first detected, a bone scan is often part of the initial work-up
- May present with pathological fractures or pain
- Biopsy or determination of primary is the only way to confirm the diagnosis
- Most common metastatic bone tumours: breast, prostate, lung, see Orthopedics, OR45

#### Metabolic Bone Disease

**Osteoporosis**
- Reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- Dual energy x-ray absorptiometry (DEXA): gold standard for measuring bone mineral density
  - T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - Osteopenia: \(-2.5 < \text{T-score} < -1\)
    - Osteoporosis: \(\text{T-score} \leq -2.5\)
  - Z-score: the number of standard deviations from the age-matched mean
  - Risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy

**Diagnostic sensitivity of DEXA highest when BMD measured at lumbar spine and proximal femur.**
• appearance on plain film
  ▪ osteopenia: reduced bone density on plain films
  ▪ may also be seen with osteomalacia, hyperparathyroidism, and disuse
  ▪ compression of vertebral bodies
  ▪ biconcave vertebral bodies ("codfish" vertebrae)
  ▪ long bones have appearance of thinned cortex and increased medullary cavity
  ▪ look for complications of osteoporosis
    ▪ e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami
• see **Endocrinology, E42**

**Osteomalacia/Rickets**
• reduction in bone mineral density, usually due to vitamin D deficiency, resulting in softening and bowing of long bones
• similar to osteoporosis, initial radiological appearance of osteopenia (coarse and poorly defined bone texture)
• “fuzzy”, ill-defined trabeculae
• Looser’s zones (pseudofracture)
  ▪ characteristic radiologic feature
  ▪ fissures or clefts at right angles to long bones and extending through cortex
• DDx: osteomalacia, chronic renal disease, fibrous dysplasia, hyperthyroidism, Paget’s, osteodystrophy, X-linked hypophosphatemia

**Hyperparathyroidism**
• most common cause is renal failure (secondary hyperparathyroidism)
• chondrocalcinosis
  ▪ calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and periarticular soft tissue)
  ▪ resorption of bone typically in hands (subperiosteal and at tufts), SI joints (subchondral), skull (“salt and pepper” appearance), osteoclastoma (brown tumours)
  ▪ “rugger jersey spine”: band-like osteosclerosis at superior/inferior margins of vertebral bodies
• see **Endocrinology, E38**

**Paget’s Disease**
• abnormal remodeling involving single or multiple bones – especially skull, spine, pelvis
• 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
• features
  ▪ coarsening of the trabeculae with bone expansion
  ▪ bone softening/bowing
  ▪ bone scan will reveal high activity, especially at bone ends
  ▪ thickened cortex
• see **Endocrinology, E46**
Nuclear Medicine

Brain

- $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) imaging to assess cerebral blood flow, taken up in cortical and subcortical grey matter; used for dementia, traumatic brain injury and to a lesser extent vasculitis, neuropsychiatric disorders and stroke
- PET imaging assesses metabolic activity by using $^{18}$FDG
- CSF imaging, intrathecal administration of $^{111}$In-DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from other causes of hydrocephalus
- ventricular shunt evaluation for obstruction (most commonly ventricular peritoneal) with $^{99m}$Tc or $^{111}$In-DTPA

Thyroid

Radioactive Iodine Uptake (see Endocrinology, E22)

- index of thyroid function (trapping and organification of iodine)
- radioactive $^{131}$I or $^{123}$I given PO to fasting patient
- measure percentage of administered iodine taken up by thyroid
- increased RAU: toxic multinodular goiter, toxic adenoma, Graves’ disease
- decreased RAU: subacute thyroiditis, late Hashimoto’s disease, hormone suppression
- falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed)

Thyroid Imaging (Scintiscan)

- $^{99m}$Tc pertechnetate IV or radioactive iodine ($^{123}$I)
- provides functional anatomic detail
- hot (hyperfunctioning) lesions
  - adenoma, toxic multinodular goiter
  - usually benign, cancer very unlikely (less than 1%)
- cold (hypofunctioning) lesions
  - cancer must be considered until biopsy negative even though only 6-10% are cancerous
- iso/intense lesions
  - cancer must be considered as an iso/intense lesion may represent cold nodules superimposed on normal tissue
  - if cyst suspected, correlate with U/S
- serum thyroglobulin to detect recurrent thyroid cancer post-treatment

Radioiodine Ablation

- $^{123}$I for Graves’ disease, multinodular goiter, thyroid cancer

Respiratory

V/Q Scan

- examine areas of lung in which ventilation and perfusion do not match
- ventilation scan
  - patient breathes radioactive gas ($^{99m}$Tc-DTPA, $^{133}$Xe, Technegas) through a closed system, filling alveoli proportionally to ventilation
  - ventilation scan defects indicate: airway obstruction, chronic lung disease, bronchospasm, tumour mass obstruction
- perfusion scan
  - radiotracer injected IV ($^{99m}$Tc-MAA) trapped in pulmonary capillaries (1 in 1500 arterioles occluded) according to blood flow
  - gives a map of pulmonary circulation
  - relatively contraindicated in severe pulmonary HTN and right-to-left shunt
  - with PE
    - areas of lung are well ventilated but not perfused (unmatched defect)
    - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
    - reported as high probability, intermediate, low very low, or normal
    - V/Q scans for PE have been largely replaced by CT scan with contrast (see Respirology, R18)
  - not valid for assessment of PE when patients have intrinsic lung diseases and ventilatory problems
Cardiac

Myocardial Perfusion Scanning
- for investigation of angina, atypical chest pain, coronary artery disease, and follow-up post-bypass
- thallium-201 (a radioactive analogue of potassium), \(^{99m}\text{Tc}\) sestamibi (MIBI), or \(^{99m}\text{Tc}\) tetrofosmin
- injected at peak exercise (physical stress) or after persantine challenge (vasodilator) and again later at rest
- persistent defect (at rest and stress) suggests infarction; reversible defect (only during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- see Cardiology and Cardiovascular Surgery, C10 for more details

Radionuclide Ventriculography
- \(^{99m}\text{Tc}\) tagged to red blood cells
- first pass through right ventricle → pulmonary circulation → left ventricle; provides information about RV function
- cardiac MUGA scan (MUltiple GAted acquisition scan) sums multiple cardiac cycles
  - evaluation of LV function
  - images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
  - MUGA scan can be used to study the function of the heart at a particular stage of contraction
- provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion

Abdomen and Genitourinary System

HIDA (Hepatobiliary IminoDiacetic Acid) Scan
- IV injection of \(^{99m}\text{Tc}\)-disofenin (DISIDA) or \(^{99m}\text{Tc}\)-mebrofenin (BRIDA) which is bound to protein, taken up, and excreted by hepatocytes into biliary system
- can be performed in non-fasting state but prefer NPO after midnight
- gallbladder visualized when cystic duct is patent, usually seen by 30 min to 1 h
- if gallbladder is not visualized, suspect obstructed cystic duct (acute or chronic cholecystitis)
- acute cholecystitis: no visualization of gallbladder at 4 h or after administration of morphine at 30 min
- chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- differential diagnosis of obstructed cystic duct: acute cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 h or more than 24 h
- filling of gallbladder rules out cholecystitis (<1% probability)
- assess bile leaks post-operatively

RBC Scan
- IV injection of radiotracer with sequential images of the abdomen (\(^{99m}\text{Tc}\ RBCs)
- GI bleed
  - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image
  - if bleeding acutely at >0.5 mL/min, use angiography (more specific)
- RBC scan is more sensitive for lower GI bleed
- liver lesion evaluation
  - hemangioma has characteristic appearance: cold early, fills in later

Renal Scan
- see Genitourinary System, MI16

Scrotal Scintigraphy
- scrotal scintigraphy has now been replaced by Doppler U/S
Bone

Bone Scan
- isotopes
  - ⁹⁹ᵐTc-diphosphonate
    - triphasic bone scan: flow → blood pool → delayed bone images
    - uptake can distinguish bone vs. soft tissue infection and septic arthritis vs. osteomyelitis vs. peripheral cellulitis
    - acute osteomyelitis: increased activity in flow, blood pool, and delayed bone images; usually does not cross joint
    - septic arthritis and cellulitis: increased activity in blood pool and normal or slightly increased activity in delayed images; may cross joint
  - ¹¹¹In WBC: tracks the active migration of the WBC, more specific for infection
  - ⁶⁷Ga citrate: may see uptake in some tumours, also more specific for infection
- radioactive tracer binds to hydroxyapatite of bone matrix
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications:
  - bone pain of unknown origin
  - AVN
  - suspected malignancy
  - staging malignancy (cancer of breast, prostate, kidney or lung)
  - follow up after treatment
  - detection and follow up of primary bone disease
  - assessment of skeletal trauma
  - detection of soft tissue calcification
  - renal failure
- differential diagnosis of positive bone scan:
  - bone metastases from breast, prostate, lung, thyroid
  - primary bone tumour
  - arthritis
  - fracture
  - infection
  - anemia
  - Paget's disease
- multiple myeloma: typically normal or cold (false negative); need a skeletal survey
- "superscan": increased bone uptake and poor renal uptake due to diffuse metastases or metabolic causes (renal osteodystrophy)

Interventional Radiology

Vascular Procedures

Angiography
- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- catheter can be placed into a large vessel (e.g. aorta, vena cava) for a "flush" or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (EVAR, thrombolysis, stenting and angioplasties)
- complications: puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
- significant complications occur in <5% of patients
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CT angiography and MR angiography)
- see Neuroradiology, MI18

Percutaneous Transluminal Angioplasty (PTA) and Stents
- introduction and inflation of a balloon into a stenosed vessel to restore distal blood supply
- common alternative to surgical bypass grafting with five year patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary and carotid artery stenoses are amenable to treatment

Thrombolytic Therapy for Pulmonary Embolism
Cochrane DB Syst Rev 2009;3:CD004437
Study: Systematic review of randomized controlled trials comparing thrombolytic therapy with placebo, heparin, or surgical intervention.
Patients: 679 patients with acute PE
Intervention: Thrombolytics vs. heparin or placebo.
Outcome: Death rate, recurrence of PE, major and minor hemorrhagic events.
Results: Non-significant difference between thrombolytics and heparin or placebo in all measured outcomes. RT-PA and heparin together reduced need for treatment for in-hospital events. Thrombolitics improved hemodynamic outcome, lung VQ scans, pulmonary angio assessment and echocardiograms greater than heparin. Need for further double-blinded RCTs.
Conclusion: We cannot conclude whether thrombolytic therapy is better than heparin for pulmonary embolism based on limited evidence found.
• vascular stents may help improve long term results by keeping the vessel wall patent after PTA
• stents are also used for angioplasty failure or complications
• stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
• complications: similar to angiography, but also includes vessel rupture

**Thrombolytic Therapy**
• may be systemic (IV) or catheter directed
• infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
• can restore blood flow in a vessel obstructed with a thrombus or embolus
• indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thrombosis (DVT or PE)
• complications: bleeding, stroke, distal embolus, reperfusion injury with myoglobinuria and renal failure if advanced ischemia present

**Embolization**
• injection of occluding material into vessels
• permanent agents: amplatzer plugs, coils, glue and onyx
• temporary: gel foam, autologous blood clots
• indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of AVM, pre-operative treatment of vascular tumours (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
• complications:
  • post embolization syndrome (pain, fever, leukocytosis)
  • unintentional embolization of a non-target organ with resultant ischemia

**Inferior Vena Cava Filter**
• insertion of metallic “umbrellas” to mechanically trap emboli and prevent PE
• may be temporary (retrievable) or permanent
• inserted via femoral vein, jugular vein, or antecubital vein
• usually placed infrarenally to avoid renal vein thrombosis
• indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation

**Central Venous Access**
• variety of devices available
• peripherally inserted central catheter (PICC), external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath*)
• indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
• complications: venous thrombosis and central venous stenosis, infection including sepsis, pneumothorax

**Nonvascular Interventions**

**Percutaneous Biopsy**
• replaces open surgical procedure
• many sites are amenable to biopsy using U/S, fluoroscopy or CT guidance
• complications:
  • false negative biopsies due to sampling error or tissue necrosis
  • pneumothorax in 30% of lung biopsies, chest tube required in approximately 5%
  • pancreatic biopsies are associated with risk of inducing acute pancreatitis
  • transjugular liver biopsies can be performed to minimize bleeding complications in patients with uncorrectable coagulopathies or ascites

**Abscess Drainage**
• placement of a drainage catheter into an infected fluid collection
• administer broad spectrum IV antibiotics prior to procedure
• routes: percutaneous (most common), transgluteal, transvaginal, transrectal
• complications:
  • hemorrhage
  • injury to intervening structures (e.g. bowel)
  • bacteremia, sepsis

Advanced ischemia patients should receive surgery rather than thrombolysis.

Chemoembolization delivers chemotherapy directly into the tumour through its feeding blood supply and traps the drug in place by embolization.

**Indications for Central Venous Access**
- FAT CAB
- Fluids
- Antibiotics
- TPN
- Chemotherapy
- Administration of blood
- Blood sampling

**Figure 36. Retrievable IVC filter**

**Figure 37. Femoral arteriogram:**
distal occlusion of superficial femoral artery

ERCP is the primary modality for distal common bile duct obstructions.
Percutaneous Biliary Drainage (PBD)/Cholecystostomy
- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications:
  - cholecystostomy: acute cholecystitis
  - percutaneous biliary drainage: biliary obstruction secondary to stone or tumour, cholangitis
- complications:
  - acute: sepsis, hemorrhage
  - long-term: tumour overgrowth and stent occlusion

Percutaneous Nephrostomy
- placement of catheter into renal collecting system
- indications: hydronephrosis (urinary obstruction as a result of a stone or tumour), pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteria and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

Gastrostomy/Gastrojejunostomy
- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications:
  - feeding: inability to eat (most commonly CNS lesion, e.g. stroke) or esophageal obstruction
  - decompression: gastric outlet obstruction
- complications: gastroesophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury

Radiofrequency (RF) Ablation
- U/S or CT guided probe is inserted into tumour, RF energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumours (HCC and metastases), renal tumours
- complications: destruction of neighbouring tissues and structures, bleeding

Breast Imaging

Modalities

Mammography
Description
- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see General Surgery, GS54)

Indications
- screening
  - begin screening from age 50 q1-2 yr
  - if over the age of 70, continue screening mammography if in good general health
  - not routinely recommended if under the age of 50 unless strong family history
  - if positive family Hx, begin screening 5-10 yr younger than the first degree relative who developed breast cancer
- diagnostic
  - signs and symptoms suggestive of breast cancer include a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, and spontaneous serous or sanguinous nipple discharge from a single duct
  - women with abnormal screening mammograms
  - follow-up of women with previous breast cancer
  - suspected complications of breast implants

Breast MRI

Description
- breast MRI should be used only after mammography and ultrasound investigation
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- use as a screening modality has been limited to high risk patients

Indications
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy
- post-surgical resection of breast cancer
- known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer
- untested first-degree relative of a carrier of such a gene mutation
- family history consistent with a hereditary breast cancer syndrome and estimated personal lifetime cancer risk >25%
- high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
- radiation therapy to chest (before age 30)
- NOTE: MRI should not be used to screen the general population or to differentiate between benign and malignant lesions

Ultrasound

Definition
- ultrasound can determine if a mass is cystic or solid and is commonly used during biopsy

Indications
- identification and characterization of palpable abnormalities
- evaluation of ambiguous mammographic findings in the determination of cystic versus solid characteristics
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- guidance for interventional procedures
- breast sonography is the initial imaging technique to evaluate palpable masses in women under 30 and in lactating and pregnant women

Breast Interventional Procedures

Description
- breast interventional procedures include fine needle aspirate biopsy, core needle biopsy, abscess drainage, and cyst aspiration (see General Surgery, GS56)

Indications
- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) or confirm diagnosis of a probable benign mass (BI-RADS® Category 3)
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical ultrasound-guided localization of a lesion
Breast Findings

Breast Masses

- **definition:** a space occupying lesion seen in two different projections; if seen in only a single projection it should be called a "density" until its three-dimensionality is confirmed

| Table 21. Mammographic Features of Benign and Malignant Breast Masses |
|---|---|---|
| **Shape** | Benign | Malignant |
| | Oval, round, lobular | Irregular |
| **Margin** | Circumscribed, well-defined | Indistinct, microlobulated, speculated |
| **Density** | Radiolucent (oil cyst, lipoma, fibrolipoma, galdactocele, hamartoma) | Radiodense |
| **Calcifications (± mass)** | Popcorn (hyalinizing fibroadenoma), lucent centred (oil cyst/fat necrosis), layering (milk of calcium), vascular, round, scattered | Pleomorphic (vary in size and shape), amorphous (indistinct), fine linear, coarse heterogenous, regional, segmental, clustered |

Other Findings

- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and centre; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetric density: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
  - if focal compression shows mass-like character, or if the area can be palpated, biopsy must be considered

The Nephron

- basic structural and functional unit of the kidney, approximately 1 million per kidney
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

The Glomerulus

- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- consists of following cell types:
  - Mesangial cells: structural cells that support the vascular tree. They are also contractile and produce vasoactive substances to help control blood flow
  - Capillary endothelial cells: one of the cells of the glomerular filtration barrier and help form the plasma filtration apparatus due to their sinusoidal nature and glyocalyx. Contribute to the production of the glomerular basement membrane (GBM)
  - Visceral epithelium (podocytes): one of the cells of the glomerular filtration barrier and help form the plasma filtration apparatus due to their interdigitated foot process that form slit diaphragms. Contribute to the production of the glomerular basement membrane (GBM)

4. Parietal epithelium

- lines the interior of Bowman's capsule and contains a podocyte progenitor population
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman's space (Figure 1)
- particles are selectively filtered by size (<60 kDa) and change (negative charge repelled)
The Renal Tubules

- reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
- each segment of the nephron selectively transports various solutes and water and is targeted by specific diuretics

![Renal Hemodynamic Parameters](image)

RBF = 20% of CO — 1 L/min
RPF = RBF*(1-Hct)
GFR = ~120 mL/min in healthy adult
(98% of this volume is reabsorbed)
FF = GFR/RPF
(normally 20%)

![Figure 1. The glomerulus](image)

**Figure 1. The glomerulus**

**The Renal Tubules**

- reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
- each segment of the nephron selectively transports various solutes and water and is targeted by specific diuretics

![Figure 2. Tubular segments of the nephron](image)

**Figure 2. Tubular segments of the nephron**
Renal Hemodynamics

- Glomerular Filtration Rate (GFR)
  - the rate of fluid transfer between glomerular capillaries and Bowman’s space
  - 180 L/d, of which 99% is reabsorbed, giving a daily urine output of 1.0-1.5 L
  - normal urine output is >0.5 ml/kg/h in adults
  - GFR is highest in early adulthood, decreasing thereafter
- renal autoregulation maintains constant GFR over mean arterial pressures of 70-180 mmHg
- 2 mechanisms of autoregulation:
  - myogenic mechanism: release of vasoactive factors in response to changes in perfusion pressure (e.g. ↑ perfusion pressure → afferent arteriolar constriction → ↓ GFR)
  - tubuloglomerular feedback: changes in [Na+] delivery to macula densa lead to afferent arteriolar tone (e.g. increased delivery causes afferent constriction)
- Filtration Fraction (FF)
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%
  - angiotensin II (AII) constricts renal efferent arterioles which increases FF thereby maintaining GFR
- renin is released from juxtaglomerular apparatus in response to decreased RPF

Assessment of Renal Function
Measurement of Renal Function

- glomerular filtration rate (GFR) = rate of filtration of plasma by the glomeruli
- most renal functions decline in parallel with a decrease in GFR
- inulin clearance is the gold standard for measuring GFR, but very rarely used clinically
- clinically, GFR is estimated using serum creatinine concentrations [Cr]
- creatinine (Cr) is a metabolite of creatine (intermediate in muscle energy metabolism)
- Cr is freely filtered at the glomerulus with no tubular reabsorption
- tubular secretion varies based on level of renal function (10% to >50%)
- rate of production determined by muscle mass
- Cr filtered = Cr excreted (at steady state)

Ways to Estimate GFR Using Serum Creatinine Concentration
1. Calculate creatinine clearance (CrCl)
   - calculation provides reasonable estimate of GFR
   - measure plasma [Cr], 24-h urine volume and urine [Cr]
     - GFR/d = (urine [Cr] x urine volume/d)/(plasma [Cr])
     - must use same units for urine [Cr] and plasma [Cr]
2. Cockcroft-Gault formula
   - serum Cr used along with age, gender and weight (kg) to estimate GFR (see sidebar)
   - normal range is >90 mL/min (>1.5 mL/s)
3. MDRD (Modification of Diet in Renal Disease) formula
   - most common way in which GFR is estimated (MDRD 7 equation)
   - complex formula incorporating age, gender, serum Cr, African descent, but does not include weight
   - GFR is reported as mL/min/1.73 m² body surface area

4. CKD-EPI equation
   - the best current equation
   - calculated using serum Cr, age, sex and race

Limitations of Using Serum Cr Measurements
1. must be in steady state
   - constant GFR and rate of production of Cr from muscles
   - sudden injury may reduce GFR substantially, but it takes time for Cr to accumulate and then re-establish steady state
   - clinical correlation: in acute kidney injury, the rise in creatinine is often delayed
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range
   - with progressive renal failure, remaining nephrons compensate with hyperfiltration
   - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
   - lower production with smaller muscle mass (i.e. female, elderly, low weight)
   - e.g. consider plasma [Cr] of 100 µmol/L (1.13 mg/dL) in both of these patients
     - 20 yr-old man who weighs 100 kg, GFR = 144 mL/min
     - 80 yr-old woman who weighs 50 kg, GFR = 30.6 mL/min
   - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum creatinine due to the age-associated decline in muscle mass
4. tubular secretion of creatinine increases as GFR decreases
   - serum creatinine and CrCl overestimate low GFR
   - certain drugs (cimetidine, trimethoprim) can interfere with Cr secretion
5. errors in Cr measurement
   - very high bilirubin level causes [Cr] to be falsely low
   - acetooacetic acid (a ketone body) and certain drugs (cefoxitin) can cause falsely high [Cr]

Measurement of Urea Concentration
- urea is the major end product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) cause urea level to rise
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in sodium-avid states such as ECF volume depletion
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and µmol/L for Cr), and 14:1 in MKS units (urea expressed as BUN in mg/dL and Cr in mg/dL)

Urinalysis
- use dipstick in freshly voided urine specimen to assess the following:

1. Specific Gravity
   - ratio of the mass of equal volumes of urine/H₂O
   - range is 1.001 to 1.030
   - values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
   - value usually 1.010 in end stage renal disease (isosthenuria)

2. pH
   - urine pH is normally between 4.5-7.0; if persistently alkaline, consider:
     - renal tubular acidosis
     - UTI with urease-producing bacteria (e.g. Proteus)

3. Glucose
   - freely filtered at glomerulus and reabsorbed in proximal tubule
   - causes of glycosuria include
     1. hyperglycemia >9-11 mmol/L (>160-200 mg/dL) leads to filtration that exceeds tubular resorption capacity
     2. increased GFR (e.g. pregnancy)
     3. proximal tubule dysfunction (e.g. Fanconi’s syndrome)

4. Protein
   - dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
   - microalbuminuria (defined as ≥2.0 mg/mmol creatinine in males and ≥2.8 mg/mmol creatinine in females) is not detected by standard dipstick (see Diabetes and the Kidney, NP28)
   - sulfosalicylic acid detects all protein in urine by precipitation
   - gold standard: 24-h timed urine collection for total protein

Clinical Settings in which Urea Level is Affected Independent of Renal Function
Disproportionate Increase in Urea
- Volume depletion (prerenal azotemia)
- GI hemorrhage
- High protein diet
- Sepsis
- Catabolic state with tissue breakdown
- Corticosteroid or cytotoxic agents

Disproportionate Decrease in Urea
- Low protein diet
- Liver disease

Estimating Urine Osmolality
Last 2 digits of the specific gravity x 30 = urine osmolality approximately
  e.g. specific gravity of 1.020 = 600 mOsm

24 h Urine Collection
- Discard first morning specimen
- Collect all subsequent urine for the next 24 h
- Refrigerate between voids
- Collect second morning specimen

Clarity: Cloudiness may indicate infection
Colour: usually pale yellow or amber, but may be colourless (diabetes insipidus, excess water intake), bright yellow (due to riboflavin ingestion or vitamin tablets), or dark yellow (concentrated urine in intravascular volume depletion)

Assessment of Renal Function  
Toronto Notes 2014
5. Leukocyte Esterase
- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation (e.g. AIN)

6. Nitrites
- nitrates in urine are converted by bacteria to nitrites
- high specificity, low sensitivity for UTI

7. Ketones
- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

8. Hemoglobin
- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis) and true hematuria (RBCs seen on microscopy)

### Urine Microscopy
- centrifuge urine specimen for 3-5 min, discard supernatant, resuspend sediment and plate on slide
- shaking tube vigorously may disrupt casts

3. CRYSTALS
- uric acid: consider acid urine, hyperuricosuria
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning
- sulfur: sulfa-containing antibiotics

Urine Electrolytes
- commonly measure: Na⁺, K⁺, Cl⁻, osmolality and pH
- no ‘normal’ values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient’s current state, e.g.:
  1. ECF volume depletion: expect low urine [Na⁺] (kidneys should be retaining Na⁺)
     - urine [Na⁺] >40 mmol/L suggests a renal problem or the action of a diuretic
     - urine [Na⁺] <20 mmol/L suggests the patient is pre-renal
  2. daily urinary potassium excretion rate should be decreased (<20 mmol/d) in hypokalemia
     - if higher than 20 mmol/d, suggests renal contribution to hypokalemia
- osmolality is useful to estimate the kidney’s concentrating ability
- FENa refers to the fractional excretion of Na⁺
  \[ \text{FE}_{\text{Na}} = \frac{\text{Urine} \ [\text{Na}^+] \times \text{Plasma} \ [\text{Cr}] }{\text{Plasma} \ [\text{Na}^+] \times \text{Urine} \ [\text{Cr}]} \]
  \[ \text{FE}_{\text{Na}} < 1\% \text{ suggests the pathology is pre-renal} \]

Examples of Common Urine Electrolyte Abnormalities
- high urine [Na⁺] (>40 mmol/L) in the setting of acute renal failure: indicates renal disease
- high urine [Na⁺] (>40 mmol/L) in the setting of hyponatremia: generally from causes such as diuretics, tubular disease (e.g. Bartter’s syndrome), SIADH
- additionally, urine pH is useful to grossly assess renal acidification
  - “low” pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA)

Electrolyte Disorders
Sodium Homeostasis
- hyponatremia and hypernatremia are disorders of water balance
  - hyponatremia usually suggests too much water in the extracellular fluid relative to Na⁺
  - hypernatremia usually suggests too little water in the extracellular fluid relative to Na⁺
- solutes (such as Na⁺, K⁺, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
  - water moves out of cells in response to increased ECF osmolality
  - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na⁺ content rather than concentration
  - Na⁺ deficiency leads to ECF volume contraction
  - Na⁺ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially in the brain) shrinking (hypermotremia) or swelling (hyponatremia)

*If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia
Hyponatremia

- hyponatremia: serum $[Na^+] < 136$ mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality

![Diagram of Approach to Hyponatremia]

### Signs and Symptoms
- depend on degree of hyponatremia and more importantly, velocity of progression from onset
- acute hyponatremia ($< 24-48$ h) more likely to be symptomatic
- chronic hyponatremia ($> 24-48$ h) less likely to be symptomatic due to adaptation
  - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
  - adaptation is responsible for the risks associated with overly rapid correction
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased level of consciousness (LOC)

### Complications
- seizures, coma, respiratory arrest, permanent brain damage, brainstem herniation, death
- risk of brain cell shrinkage with rapid correction of hyponatremia
  - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis: cranial nerve palsies, quadriplegia, decreased LOC)

### Risk Factors for Osmotic Demyelination
- rise in serum $[Na^+]$ with correction $> 8$ mmol/L/d if chronic hyponatremia
- associated hypokalemia and/or malnutrition (i.e. low muscle mass)
- if patient with hyponatremia and hypovolemia is given large volume of isotonic fluid (ADH is stimulated by hypovolemia; when hypovolemia is corrected, the ADH level falls suddenly causing sudden brisk water diuresis, and therefore rapid rise in serum $Na^+$ level)
- patient with psychogenic polydipsia, deprived of water

### Investigations
- ECF volume status assessment
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine $Na^+$ (urine $Na^+$ $< 10-20$ mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 6)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. small cell lung Ca)
- consider CT head if suspect CNS cause
Treatment of Hyponatremia

- general measures for all patients
  - water restriction to <1 L/d (unless hypovolemic give normal saline)
  - treat underlying cause
  - monitor serum Na+ frequently to ensure correction is not occurring too rapidly
  - monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia

Table 5. Treatment of Acute and Chronic Hypoosmolar Hyponatremia

<table>
<thead>
<tr>
<th>Onset</th>
<th>Symptomatic</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acute (&lt;48 h)</td>
<td>Yes</td>
<td>Rapid correction (Hypertonic 3% saline)</td>
</tr>
<tr>
<td></td>
<td>No</td>
<td>Rapid correction only if marked drop in Na+</td>
</tr>
<tr>
<td>Chronic (&gt;48 h)</td>
<td>Yes</td>
<td>Slow correction (Hypertonic 3% saline)</td>
</tr>
<tr>
<td></td>
<td>No</td>
<td>Water restriction, NS, NaCl tablet</td>
</tr>
</tbody>
</table>

A. Definitely Acute (known to have developed over <24-48 h)

- commonly occurs in hospital (dilute IV fluid, post-operative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
  - correct rapidly with 3% NaCl 1-2 cc/kg/h up to serum [Na+] = 125-130 mmol/L
  - may need furosemide to address volume overload
- if asymptomatic, treatment depends on severity
  - if marked fall in plasma [Na+], treat as symptomatic

B. Chronic or Unknown

1. if severe symptoms (seizures or decreased LOC)
   - must partially correct acutely
   - aim for increase of Na+ by 1-2 mmol/L/h for 4-6 h
   - limit total rise to 8 mmol/L in 24 h
   - IV 3% NaCl at 1-2 cc/kg/h
   - may need furosemide
2. if asymptomatic
   - water restrict to <1 L/d fluid intake
   - consider IV 0.9% normal saline (NS) + furosemide (reduces urine osmolality, augments excretion of H₂O)
   - consider NaCl tablet or Oxocubes® as a source of Na+
3. refractory
   - furosemide and IV NS
   - demeclocyline 300-600 mg PO bid (antagonizes effect of ADH on collecting duct; avoid if cirrhosis or congestive heart failure as nephrotoxic in these settings)
   - extra osmoles – give oral urea (increases loss of water without Na+, 30-60 g/d)
   - slow rate of IV 3% NaCl (e.g. 10 cc/h = 120 mmol/d of sodium which will increase serum [Na+] by about 3 mmol/L/d)
4. always pay attention to patient's ECF volume status – if already volume-expanded, unlikely to give NaCl; if already volume-depleted, almost never appropriate to give furosemide

C. Options if overly rapid correction occurs

- give water (IV D5W)
- give ADH to stop water diuresis (DDAVP 1-2 µg IV)

Impact of IV Solution on Plasma Na+

- formula to estimate the change in serum Na+ caused by retention of 1 L of any infusate
  \[
  \text{TBW} = (\text{for men}) 0.6 \times \text{wt(kg)}; (\text{for women}) 0.5 \times \text{wt(kg)}
  \]
  \[
  \text{change in serum [Na+] = } \frac{\text{infusate [Na+] - serum [Na+]}}{\text{TBW} + 1 \text{ L}}
  \]
  \[
  \text{formula assumes there are no losses of water or electrolytes}
  \]

SYNDROME OF INAPPROPRIATE ANTI DIURETIC HORMONE SECRETION (SIADH)

1. urine that is inappropriately concentrated for the serum osmolality
2. high urine sodium (>20-40 mmol/L)
3. high FEₙₙₙ

Beware of Rapid Correction of Hyponatremia

- Inadvertent rapid correction of hyponatremia can easily occur
- e.g. patient with hyponatremia due to SIADH from nausea
- Anti-emetic given for relief of hyponatremia-induced nausea
- ADH quickly turned off in the absence of nausea, the kidneys rapidly excrete the excess free water, and the serum [Na+] rises rapidly
- Patient at risk of osmotic demyelination
- High output dilute urine (>100 cc/h, <100 mOsm/L) in the setting of hyponatremia is usually the first sign of dangerously rapid correction of serum sodium

Correction of Na+ in hyponatremia should not exceed 8 mmol/L/24 h unless definitely known to be <24-48 h duration. Frequent monitoring of serum Na+ and urine output is essential.

Concentration of Na+ in Common Infusates

- Na+ in 0.45% NaCl = 77 mmol/L
- Na+ in 0.9% NaCl = 154 mmol/L
- Na+ in 3% NaCl = 513 mmol/L
- Na+ in 5% NaCl = 855 mmol/L
- Na+ in Ringer's lactate = 130 mmol/L
- Na+ in D5W = 0

</tbody>
</table>

Hyponatremia

- serum [Na⁺] < 135 mmol/L
- too little water relative to total body Na⁺; always a hyposmolar state
- usually due to net water loss, rarely due to hypertonic Na⁺ gain
- results from problems with water intake (access, thirst) and/or site of increased water loss (renal or extrarenal)
- less common than hyponatremia because patients are protected against hyponatremia by thirst and release of ADH

Signs and Symptoms
- with acute hyponatremia no time for adaptation, therefore more likely to be symptomatic
- adaptive response: cells import and generate new osmotically active particles to normalize size
- due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

Complications
- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema due to ongoing brain hyposmolarity

Table 7. Treatment Hypovolemic and Hypervolemic Hyponatremia

<table>
<thead>
<tr>
<th>Volume Status</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypovolemic</td>
<td>Give free water OR by NG tube</td>

</tr>
<tr>
<td>Hypervolemic</td>
<td>Diuresis or dialysis (D5W once fluid deficit)</td>
</tr>
</tbody>
</table>

Treatment of Hypovolemic Hyponatremia
- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum Na⁺ frequently to ensure correction is not occurring too rapidly
  - if evidence of hemodynamic instability, must first correct volume depletion with NS bolus
  - loss of water is often accompanied by loss of Na⁺ but a proportionately larger water loss
  - in patients with presumed normal total body Na⁺ content, use formula to calculate H₂O deficit
  (see sidebar)
  - replace free water deficit
  - encourage patient to drink pure water, as oral route is preferred for fluid administration
  - if unable to replace PO or NG, correct H₂O deficit with hypotonic IV solution
  - use formula (see Hyponatremia, NP9) to estimate expected change in serum Na⁺ with 1L infusate
  - aim to lower [Na⁺] by no more than 12 mmol/L in 24 h (0.5 mmol/L/h)
  - must also provide maintenance fluids and replace ongoing losses
  - rule of thumb: give 2 cc/kg/h of free water to correct serum [Na⁺] by about 0.5 mmol/L/h or 12 mmol/L/d

Correction of serum [Na⁺] in hyponatremia should not exceed 12 mmol/L/24 h.

Table 7. Treatment Hypovolemic and Hypervolemic Hyponatremia

<table>
<thead>
<tr>
<th>Volume Status</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypovolemic</td>
<td>Give free water OR by NG tube</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td>Hypervolemic</td>
<td>Diuresis or dialysis (D5W once fluid deficit)</td>
</tr>
</tbody>
</table>

Treatment of Hypervolemic Hyponatremia
- general measures as above
- hypervolemic hyponatremia: remove excess total body Na⁺ with diuresis or dialysis (if renal failure present), then replace water deficit using D5W

Correction of serum [Na⁺] in hyponatremia should not exceed 12 mmol/L/24 h.

1 L D5W approximately equals 1 L of free water
1 L 0.45% NS approximately equals 500 mL of free water
DIABETES INSIPIDUS (DI)
• collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
• central defect in release of ADH (central DI) or renal response to ADH (nephrogenic DI)

Etiology
• central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
• nephrogenic DI: lithium (most common), hypokalemia, hypercalcemia, and congenital

Diagnosis
• urine osmolality inappropriately low in patient with hypernatremia ($U_{\text{osm}} < 300 \text{ mOsm/kg}$)
• serum vasopressin concentration may be absent or low (central), or elevated (nephrogenic)
• dehydration test: $\text{H}_2\text{O}$ deprivation until loss of 3% of body weight or until urine osmolarity rises above plasma osmolarity; if fails to concentrate urine, most likely DI
• administer DDAVP (exogenous ADH) (10 µg intranasally or 2 µg SC or IV):
  • central DI: diagnosed if there is rise in urine osmolality, fall in urine volume
  • nephrogenic DI: exogenous ADH fails to concentrate urine as kidneys do not respond
  • treat with water (IV D5W or PO water), thiazides may help as well (reduced ECF volume stimulates proximal tubular reabsorption of sodium and water, leading to less delivery of glomerular filtrate to ADH sensitive parts of renal tubule, and therefore lower urine volume results)

Potassium Homeostasis
• approximately 98% of total body $K^+$ stores are intracellular
• normal serum $K^+$ ranges from 3.5-5.0 mEq/L
• in response to $K^+$ load, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia
• insulin, catecholamines, and acid-base status influence $K^+$ movement into cells
• aldosterone has a minor effect
• potassium excretion is regulated at the distal nephron
  • $K^+$ excretion = urine flow rate $\times$ urine $[K^+]$

Factors which Increase Renal $K^+$ Loss
• hyperkalemia
• increased distal tubular urine flow rate and Na$^+$ delivery (thiazides and loop diuretics)
• increased aldosterone activates epithelial sodium channel (eNaC) in cortical collecting duct, causing Na$^+$ reabsorption and $K^+$ excretion
• metabolic alkalosis
• hypomagnesemia
• increased non-reabsorbable anions in tubule lumen: $\text{HCO}_3^-$, penicillin, salicylate

Hypokalemia
• serum $[K^+] < 3.5 \text{ mEq/L}$

Signs and Symptoms
• usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
• nausea, vomiting, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
• if severe: arrhythmias, muscle necrosis, and rarely paralysis with eventual respiratory impairment
• arrhythmias occur at variable levels of $K^+$; more likely if digoxin use, hypomagnesemia, or CAD
• ECG changes are more predictive of clinical picture than serum $[K^+]$
  • U waves most important (low amplitude wave following a T wave)
  • flattened or inverted T waves
  • depressed ST segment
  • prolongation of Q-T interval
  • with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity

Figure 5. ECG changes in hypokalemia
Approach to Hypokalemia
1. emergency measures: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of K⁺ as cause of hypokalemia
3. assess contribution of dietary K⁺ intake
4. spot urine K:Cr, should be less than 1 in setting of hypokalemia
   - if <1 consider GI loss
   - if >1 consider renal loss
5. consider 24-h K⁺ excretion
6. if renal K⁺ loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum [Mg²⁺]

Hyperkalemia
- serum [K⁺] > 5.0 mEq/L

Signs and Symptoms
- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniagenesis and metabolic acidosis
- ECG changes and cardiotoxicity (do not correlate well with serum $[K^+]$)
  - peaked and narrow T waves
  - decreased amplitude and eventual loss of P waves
  - prolonged PR interval
  - widening of QRS and eventual merging with T wave (sine-wave pattern)
  - AV block
  - ventricular fibrillation, asystole

Figure 7. ECG changes in hyperkalemia

</table>

Approach to Hyperkalemia
1. emergency measures: obtain ECG, if life threatening begin treatment immediately
2. rule out factitious hyperkalemia; repeat blood test
3. hold exogenous $K^+$ (PO and IV), and any $K^+$ retaining medications
4. assess potential causes of transcellular shift
5. estimate GFR (calculate CrCl using Cockcroft-Gault)

Treatment
- acute therapy is warranted if ECG changes are present, or if patient is symptomatic
- tailor therapy to severity of increase in $[K^+]$ and ECG changes
  - $[K^+] < 6.5$ and normal ECG
    - treat underlying cause, stop $K^+$ intake, increase the loss of $K^+$ via urine and/or GI tract (see below)
  - $[K^+]$ between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  - $[K^+] > 7.0$ and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

1. Protect the Heart
- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes cardiac toxicity of hyperkalemia, protects cardiac conduction system, no effect on serum $[K^+]$
- onset within minutes, lasts 30-60 min (N.B. May require repeat doses during treatment course of hyperkalemia)
2. Shift K⁺ into Cells
- regular insulin (Insulin R) 10-20 units IV, with 1-2 amp D50W (give D50W before insulin)
  - onset of action 15-30 min, lasts 1-2 h
  - monitor capillary blood glucose q1h because of risk of hypoglycemia
  - can repeat every 4-6 h
  - caution giving D50W before insulin if hyperkalemia is severe as it can cause a serious arrhythmia
- NaHCO₃ 1-3 ampules (given as 3 ampules of 7.5% or 8.4% NaHCO₃ in 1L D5W)
  - onset of action 15-30 min, transient effect, drives K⁺ into cells in exchange for H⁺
  - more effective if patient has metabolic acidosis
- β₂-agonist (Ventolin®) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  - onset of action 30-90 min, stimulates Na⁺/K⁺ ATPase
  - caution if patient has heart disease as tachycardia may result from this high dose of β₂-agonist

3. Enhance K⁺ Removal from Body
- via urine (preferred approach)
  - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  - fludrocortisone (synthetic mineralocorticoid) if suspect aldosterone deficiency
- via gastrointestinal tract
  - cation-exchange resins: calcium resonium or sodium polystyrene sulfonate (Kayexalate®)
    (increasingly falling out of favor due to risk of colonic necrosis; works by binding Na⁺ in exchange for K⁺, and controversial how much K⁺ is actually removed – main benefit may be the diarrhea it causes) plus lactulose PO to avoid constipation (must ensure that patient has a bowel movement after resin is administered)
  - Kayexalate® enemas with tap water (and definitely not with sorbitol as rectal sorbitol can cause colonic necrosis)
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

---

**Acid-Base Disorders**

- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic and CNS function
- see Respirology R5 for more information on respiratory acidosis/alkalosis
- normal concentration of HCO₃⁻ = 24 mEq/L (range: 22-30)
- normal pCO₂ = 40 mmHg (range: 36-44)
- each acid base disorder has an appropriate compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder
  - e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis

---

**Figure 8. Approach to acid-base disorders**
Approach

1. Identify the primary disturbance (Figure 8)
   - respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

2. Evaluate compensation. If compensation is not appropriate, a second acid-base disorder is likely present
   - compensation occurs in the same direction as the primary disturbance
     - metabolic acidosis: for every 1 mmol/L decrease in HCO₃⁻, pCO₂ should decrease by 1 mmHg
     - metabolic alkalosis: for every 10 mmol/L increase in HCO₃⁻, pCO₂ should increases by 5-7 mmHg
     - respiratory acidosis: for every 10 mmHg increase in pCO₂, HCO₃⁻ should increase by 1 (acute) or 3 (chronic) mmol/L
     - respiratory alkalosis: for every 10 mmHg decrease in pCO₂, HCO₃⁻ should decrease by 2 (acute) or 5 (chronic) mmol/L

3. Calculate Plasma Anion Gap (AG)
   - AG = [Na⁺] – ([HCO₃⁻] + [Cl⁻])
   - baseline = 12, range 10-14
   - AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 (e.g. if plasma [albumin]= 20 g/L, expect AG = 6)

4. If AG elevated, compare increase in AG with decrease in HCO₃⁻
   - if increase in AG < decrease in HCO₃⁻, there is a coexisting non-AG metabolic acidosis
   - if increase in AG > decrease HCO₃⁻, there is a coexisting metabolic alkalosis

5. Calculate Osmolar Gap
   - osmolar gap = measured osmolality – calculated osmolality
     - calculated osmolality = (2 x [Na⁺]) + [urea] + [glucose] (all units are in mmol/L)
     - normal osmolar gap <10
     - if AG >10, consider: methanol poisoning, ethylene glycol poisoning, OR another cause of acidosis plus ethanol ingestion

Metabolic Acidosis

Etiology and Pathophysiology

1. Increased Metabolic Acidosis (4 types)
   1. L-lactic acid
      - Type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
      - Type B: non-hypoxic – multiple causes. The most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease. Other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain antiretrovirals, large tumours, mitochondrial myopathies
      - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
        - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria that produce D-lactic acid, a carbohydrate load, diminished colonic motility and impaired D-lactate metabolism
   2. Ketoacidosis
      - diabetic
      - starvation
      - alcoholic (decreased carbohydrate intake and vomiting)
   3. Toxins
      - methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
      - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
      - salicylate (e.g. ASA) overdose, causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacid (salicylate activates fat breakdown)
   4. Advanced renal failure (i.e. serum Cr increased at least 5x above baseline – a very low GFR causes anion retention, and renal disease leads to impaired bicarbonate production)
2. Normal AG Metabolic Acidosis (Hyperchloremic Acidosis)

- diarrhea (HCO3⁻ loss from GI tract)
- RTA (renal tubular acidosis)
  - type I RTA (distal): inability to secrete H⁺ in collecting duct, leading to impaired excretion of ammonium into urine
  - type II RTA (proximal): impaired HCO3⁻ reabsorption
  - type IV RTA: defective ammoniagenesis due to decreased aldosterone, hyporesponsiveness or hyperkalemia

- to help distinguish renal causes from non-renal causes, use Urine Anion Gap = (Na⁺ + K⁺) – Cl⁻

  - if <0, suggests adequate NH4⁺ in urine (likely nonrenal cause: diarrhea)
  - if >0, suggests problem is lack of NH4⁺ in urine (e.g. distal RTA)

Treatment of Metabolic Acidosis

- treat underlying cause
  - insulin for DKA
  - ethanol + dialysis for methanol or ethylene glycol poisoning
  - alkaline diuresis ± dialysis if ASA overdose
- correct coexisting disorders of K⁺ (see Hyperkalemia, NP12)
- consider treatment with exogenous alkali (e.g. NaHCO3) if:
  - severe reduction in [HCO3⁻] e.g. <8 mmol/L, especially with very low pH (<7)
  - no metabolizable anion (e.g. salicylate, formate, oxalate, sulphate, since these cannot be further metabolized)

- note: lactate and ketoacid anions can be metabolized to HCO3⁻
- risks of sodium bicarbonate therapy
  - hypokalemia: causes K⁺ to shift into cells (correct K⁺ deficit first)
  - ECF volume overload: Na⁺ load given with NaHCO3 can exacerbate pulmonary edema
  - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to HCO3⁻ and persisting hyperventilation

Metabolic Alkalosis

Pathophysiology

- requires initiating event and maintenance factors
- precipitating factors
  - GI (vomiting, NG tube) or renal loss of H⁺
  - exogenous alkali (oral or parenteral administration), milk alkali syndrome
  - diuretics (contraction alkalosis): decreased excretion of HCO3⁻, decreased ECF volume, therefore increased [HCO3⁻]
  - post-hypercapnia: renal compensation for respiratory acidosis is HCO3⁻ retention, rapid correction of respiratory disorder results in transient excess of HCO3⁻
- maintenance factors
  - volume depletion: increased proximal reabsorption of NaHCO3 and increased aldosterone
  - hyperaldosteronism (1º or 2º; distal Na⁺ reabsorption in exchange for K⁺ and H⁺ excretion leads to HCO3⁻ generation; aldosterone also promotes hypokalemia
  - hypokalemia: transtubular K⁺/H⁺ exchange, stimulus for ammoniagenesis and HCO3⁻ generation

Figure 9. Approach to metabolic alkalosis
Evaluate Compensation (identify co-existing respiratory acid-base disorders)
- hypoventilation (an upper limit to compensation exists – breathing cannot be stopped; see Figure 9)

Treatment
- treat underlying cause
- correct underlying disease, replenish K⁺ and Mg²⁺ deficits, and possibly K⁺-sparing diuretic
- saline sensitive metabolic alkalosis (most common)
  - treatment: volume repletion
  - ± carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of HCO₃⁻ in urine
- saline resistant metabolic alkalosis
  - ECF volume normal or high
  - usually aldosterone or glucocorticoid excess
  - remove source of aldosterone or glucocorticoid ± spironolactone

Vascular Diseases of the Kidney

Large Vessel Disease

Table 10. Summary of Vascular Diseases

</tbody>
</table>

1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)
- important, potentially reversible cause of renal failure

Etiology
- abdominal trauma, surgery, embolism, vasculitis, extra-renal compression, hypercoagulable state, aortic dissection
- kidney transplant more vulnerable

Signs and Symptoms (depend on presence of collateral circulation)
- fever, nausea, vomiting, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4 times upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset hypertension (activation of RAAS) or sudden worsening of long-standing hypertension
- renal dysfunction, i.e. elevated Cr (if bilateral, or solitary functioning kidney)

Investigations
- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or magnetic resonance angiography, duplex Doppler studies (operator dependent)

Treatment
- prompt localization of occlusion and restoration of blood flow
- anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

2. ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)
- chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
- significant cause of ESRD: 15% in patients over 50 yr old (higher prevalence if significant vascular disease)
- usually associated with large vessel disease elsewhere
- causes of renal artery stenosis:
  - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
  - electrolytes, osmolality (gently rehydrate when needed, i.e. CHF)
  - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr) (gently rehydrate when needed, i.e. CHF)
- when there is decreased renal blood flow (RBF), GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the filtration fraction (GFR/RBF)
most common cause of secondary hypertension ("renovascular hypertension"), 1-2% of all hypertensive patients

- etiology
  - decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
  - increased angiotensin raises blood pressure in two ways
    1. causes generalized arteriolar constriction
    2. release of aldosterone increases Na⁺ and water retention
  - elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN

Risk Factors
- >50 yr old
- smoking
- other atherosclerotic disease (dyslipidemia, diabetes, diffuse atherosclerosis)

Signs and Symptoms
- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

Investigations
- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (i.e. captopril renal scan)
- renal arteriography (gold standard)

Treatment
- surgical: percutaneous angioplasty ± stent, surgical revascularization, occasionally surgical bypass
- medical: BP lowering medications (ACEI is drug of choice if unilateral renal artery disease but contraindicated if bilateral renal artery disease)
- little or no benefit if therapy is late i.e. kidney is already shrunken (however, therapy can be considered to save the opposite kidney if normal)

3. RENAL VEIN THROMBOSIS

Etiology
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical presentation determined by rapidity of occlusion and formation of collateral circulation

Signs and Symptoms
- acute: nausea/vomiting, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria and/or tubule dysfunction

Investigations
- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

Treatment
- thrombolytic therapy ± percutaneous thrombectomy for acute RVT
- anticoagulation with heparin then warfarin (1 yr or indefinitely, depending on risk factors)

Small Vessel Disease

1. HYPERTENSIVE NEPHROSCLEROSIS
- see Hypertension, NP30

2. ATHEROEMBOLIC RENAL DISEASE
- progressive renal insufficiency due to embolic obstruction of small and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease

investigations:
- eosinophilia, eosinophiluria and hypocomplementia
- renal biopsy: needle-shaped cholesterol clefs (due to tissue-processing artifacts) with surrounding tissue reaction in small/medium-sized vessels

- treatment:
  - no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- prognosis: poor overall, at least a third will develop ESRD

3. THROMBOTIC MICROANGIOPATHY
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- treatment:
  - depends on cause
  - supportive therapy
  - TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)

- avoid platelet transfusions and ASA

4. CALCINEURIN INHIBITOR NEPHROPATHY
- cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplant (e.g. heart)
- acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
- pre-renal azotemia
- treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
- chronic: result of obliterative arteriolopathy causing interstitial nephritis and CRF ( striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

Glomerular Disease

Histological Terms of Glomerular Changes

Extent of Changes
- terms used to describe histologically the number of glomeruli affected in a given condition:
  - diffuse: majority of glomeruli abnormal (>50%)
  - focal: some glomeruli affected
- terms used to describe histologically the extent to which individual glomeruli are affected in a given condition:
  - global: entire glomerulus abnormal
  - segmental: only part of the glomerulus abnormal

Types of Changes
- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane
- crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman's space

Clinical Presentation of Glomerular Disease

Important Points to Remember
- glomerular disease has diverse clinical presentations including hematuria, proteinuria, hypertension, edema and decreased GFR
- each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses):
  - acute nephritis
  - rapidly progressive glomerulonephritis
  - nephrotic
  - asymptomatic urinary abnormalities

Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation (ELITE-Symphony Trial) NEJM 2007;357:2562-2575

Study: Multicentre, randomized controlled trial with 12 mo follow-up.

Patients: 1645 patients scheduled to receive a single organ kidney transplant.

Intervention: Mycophenolate mofetil, corticosteroids and either: 1) standard dose cyclosporine; 2) low dose cyclosporine with daclizumab induction; 3) low dose tacrolimus with daclizumab induction; 4) low dose sirolimus with daclizumab induction.

Primary Outcome: Estimated Cockcroft-Gault GFR 12 mo after transplantation.

Results: the Tacrolimus arm showed significantly higher eGFR at 12 mo compared to all other arms (65.4 mL/min vs. 57.1, 59.4, 56.7 for arms 1, 2, 4 respectively; p<0.001). The Tacrolimus arm also showed decreased rates of acute rejection at 6 mo and 12 mo vs. all arms (p<0.001); improved allograft survival against standard dose cyclosporine and sirolimus; and decreased treatment failure against all other arms. There was no difference in overall patient survival between groups. Sirolimus has the highest incidence of lymphoedema, delayed wound healing, and serious adverse events; tacrolimus has significantly higher rates of new-onset diabetes; and cyclosporine regimes had the lowest incidence of diarrhea but highest opportunistic infection rates.

Conclusion: Immunosuppression regiments using low dose tacrolimus and daclizumab induction decrease nephrotoxicity while maintaining therapeutic immunosuppression in renal transplant patients.
glomerulopathies can be caused by a primary disease OR can occur secondary to a systemic disease
some glomerulopathy can present as more than one syndrome at different times

The Nephritic-Nephrotic Spectrum
glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic and pure nephrotic syndromes at the extremes (see Figure 10)

PROTEINURIA
hallmark of nephrotic syndromes
24-h urine protein: gold standard to assess degree of proteinuria
urea albumin-to-creatinine ratio (ACR): used to screen for diabetic nephropathy
microalbuminuria
defined as ACR ≥2.8 mg/mmol (female) or ≥2.0 mg/mmol (male)
marker of vascular endothelial function
an important prognostic marker for kidney disease in diabetes and hypertension (see Diabetes, NP28)
an elevated ACR ≥2.0 or 2.8 mg/mmol is the earliest sign of diabetic nephropathy
composition of normal total urine protein
upper limit of normal daily excretion of total protein is 150 mg/d
upper limit of normal daily excretion of albumin is 30 mg/d
the other normally excreted proteins are either filtered low molecular weight proteins (such as immunoglobulin, light chains or β-2 microglobulin) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)

PATHOLOGIC PROTEINURIA
Tubulointerstitial
Normally low molecular weight (LMW) proteins (<60 kD) pass through glomerular filtration barrier and are reabsorbed in proximal tubule
Proximal tubule dysfunction causes impaired reabsorption and increased excretion of LMW proteins
Albumin (>60 kD) is NOT affected. Thus, edema is partly secondary to salt and water retention
Glomerular
Normally, the filtration barrier is selectively permeable to SIZE (<60 kD) and CHARGE (repels negative particles). Thus, albumin is filtered to a very limited extent through a normal glomerulus
Damage to any component of the glomerular filtration barrier results in loss of albumin and other high MW proteins. Thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)
Overflow
Increased production of LMW proteins which exceeds the reabsorptive capacity of the proximal tubule
Plasma cell dyscrasias: produce light chain Ig (multiple myeloma, Waldenstrom’s macroglobulinemia, monoclonal gammopathy of undetermined significance)

<td>Possible tubular disease because of failure to reabsorb filtered proteins</td>
</tr>
</tbody>
</table>

Investigations
- urine R&M, C&S, urea, Cr
- further workup (if degree of proteinuria >0.5 g/d, casts and/or hematuria)
  - CBC, glucose, electrolytes, 24-h urine protein and Cr
  - urine and serum immunoelectrophoresis, abdominal/pelvic ultrasound
  - serology: ANA, RF, p-ANCA (MPO), c-ANCA, (PR3) Hep B, Hep C, HIV, Anti-steptolysin-O (ASOT)
- indications for nephrology referral
  - generally, if there is ‘heavy’ proteinuria, should refer to nephrologist
  - heavy proteinuria is ACR >30 mg/mmol
- definitely if there is nephrotic syndrome: marked proteinuria >3.5 g/1.73m²/d with hypoalbuminemia (<35 g/L)

HEMURATURIA
- hallmark of nephritic syndromes
- presence of blood or RBCs in urine
  - gross hematuria: pink, red, or tea-coloured urine
    - in gross hematuria, the urine should be centrifuged:
      - if the sediment is red, true hematuria.
      - if the supernatant is red, test for heme with a dipstick
        - if supernatant +ve for heme: myoglobinuria or hemoglobinuria
        - if –ve for heme: pseudohematuria. Consider medications (e.g. rifampin), food dyes (e.g. beets) or metabolites (e.g. porphyria)
  - microscopic hematuria: normal coloured urine, >2-3 RBCs/HPF on microscopy

Red Urine/Hematuria

- –ve dipstick, no RBCs
  - Pseudohematuria
  - Food (beets), dyes, medication (rifampin)
- +ve dipstick, +ve RBCs (true hematuria)
  - Hemoglobin (hemolysis)
- +ve dipstick, no RBCs (malignant)
  - Myoglobin (rhabdomyolysis)
- Hematological
  - Coagulopathy, sickle cell
- Renal
  - Nephrolithiasis, trauma, tumour, prostatitis, urethritis
  - Dysuria or flank pain common
  - Isomorphic RBCs, no casts
  - Blood at beginning (urethritis) or end (prostate, bladder) of stream
- Primary
  - Membrane-proliferative GN
  - Post-streptococcal GN
  - Rapidly-progressive GN
  - Interstitial nephritis (acute and chronic)
  - Papillary necrosis
  - IgA nephropathy
- Secondary
  - Connective tissue diseases (CTD)
    - Wegener’s, Goodpasture’s, SLE, Chung-Strauss, HSP
  - Infection
    - Pyelonephritis
  - Hereditary
    - Alport’s, polycystic kidney disease (PCKD)

Investigations for Hematuria
- Hx and Px: family history of nephrolithiasis, hearing loss (Alport’s), cerebral aneurysm (PCKD), diet, recent URTI, irritative and obstructive urinary symptoms (UTI)
- urine R&M, C&S, urea, Cr
- renal ultrasound
- 24-h urine stone workup if there is a history of stone formation or if there is a stone noted on imaging: calcium, oxalate, citrate, magnesium, uric acid, cysteine
Glomerular Syndromes

1. Acute NEPHRITIC SYNDROME
   • a subset of nephritic syndrome in which the clinical course proceeds over days

Etiology
   • etiology can be divided into low and normal complement levels (Figure 13)
   • frequently immune-mediated, with Ig and C3 deposits found in GBM
   • outcome dependent on etiology

Clinical/Lab Features
   • proteinuria (but <3.5 g/1.73 m²/d), abrupt onset hematuria (microscopic or macroscopic, azotemia (increased Cr and urea), RBC casts and/or dysmorphic RBCs in urine, oliguria, HTN (due to salt and water retention), peripheral edema/puffy eyes, smoky urine (see sidebar)

2. RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS (Rpgn)/CREASENTIC GLOMERULONEPHRITIS
   • a subset of nephritic syndrome in which the clinical course proceeds over weeks to months
   • clinical diagnosis, not histopathological
   • any cause of glomerulonephritis can present as RPGN (except minimal change disease)
   • additional etiologies seen only as RPGN: Goodpasture’s syndrome and granulomatosis with polyangiitis (previously called Wegener’s granulomatosis)

Clinical/Lab Features
   • fibrous crescents typically present on renal histopathology
   • RBC casts and/or dysmorphic RBCs in urine
   • classified by immunofluorescence staining (see Figure 13)
   • Type I: Anti-GBM mediated (15% of cases)
   • Type II: Immune Complex Mediated (24% of cases)
   • Type III: Non-Immune Mediated (60% of cases)
   • Type IV: Double Antibody Positive Disease (RPGN Type IV)
     • Has features of Type I and Type III
     • Double antibody positive

3. NEPHROTIC SYNDROME

Clinical/Lab Features
   • heavy proteinuria (>3.5 g/1.73 m²/d)
   • hypoalbuminemia
   • edema
• hyperlipidemia (elevated LDL cholesterol, lipuria (fatty casts and oval fat bodies on microscopy)
• hypercoagulable state (due to antithrombin III, Protein C and Protein S urinary losses)
• patient may report frothy urine
• glomerular pathology on renal biopsy:
  • minimal change disease (or minimal lesion disease or nil disease) – i.e. glomeruli appear normal on light microscopy
  • membranous glomerulopathy
  • focal segmental glomerulosclerosis (FSGS)
  • membranoproliferative glomerulonephritis
  • nodular glomerulosclerosis
• each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause proteinuria without obvious glomerular pathology)

Table 12. Nephrotic Syndrome

4. ASYMPTOMATIC URINARY ABNORMALITIES

Clinical/Lab Features
• proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
  • isolated proteinuria
  • can be postural
  • occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
• hematuria with or without proteinuria
  • IgA nephropathy (Berger's disease): most common type of primary glomerular disease worldwide, usually presents after viral URTI
  • hereditary nephritis (Alport's disease): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
  • thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
  • benign recurrent hematuria: hematuria associated with febrile illness, exercise or immunization; a diagnosis of exclusion after other possibilities are ruled out

Investigations for Glomerular Disease

• blood work
  • first presentation: electrolytes, Cr, urea, albumin, fasting lipids
  • determining etiology: CBC, ESR, serum immunoelectrophoresis, anti-GBM, C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT (anti-streptolysin titres), VDRL, HIV
• urinalysis: RBCs, WBCs, casts, protein
• 24-h urine for protein and CrCl
• radiology
  • CXR (infiltrates, CHF, pleural effusion)
  • renal ultrasound
• renal biopsy (percutaneous or open) if heavy proteinuria or renal insufficiency, and cause not obviously diabetic nephropathy
• urine immunoelectrophoresis
  • for Bence-Jones protein if proteinuria present

Secondary Causes of Glomerular Disease

Amyloidosis
• nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
• presents as nephrotic range proteinuria with progressive renal insufficiency
• can be primary or secondary
• secondary causes: multiple myeloma, TB, rheumatoid arthritis, malignancy
Systemic Lupus Erythematosus (SLE)
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- glomerulonephritis caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

Henoch-Schönlein Purpura (HSP)
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia and fever
- glomeruli show varying degrees of mesangial hypercellularity
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

Goodpasture’s Disease
- antibodies against type IV collagen present in lungs and GBM
- more common in 3rd and 6th decades of life, men slightly more affected than females
- present with RPGN type I and hemoptysis/dyspnea
- pulmonary hemorrhage more common in smokers and males
- treat with plasma exchange, cyclophosphamide, prednisone

ANCA Associated Vasculitis [i.e. Granulomatosis with Polyangiitis and Microscopic Polyangiitis (formerly Wegener’s Granulomatosis)]
- pr3-ANCA (c-ANCA) most commonly associated with the clinical picture of granulomatosis with polyangiitis (previously called Wegener’s granulomatosis)
- mpo-ANCA (p-ANCA) most commonly associated with the clinical picture of microscopic polyangiitis
- renal involvement very common
- focal segmental necrotizing RPGN with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treating typically involves cyclophosphamide and prednisone

Cryoglobulinemia
- cryoglobulins: monoclonal IgM and polyclonal IgG
- presents as purpura, fever, Raynaud’s phenomenon and arthralgias
- at least 50% of patients have hepatitis C
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat hepatitis C, plasmapheresis
- overall prognosis: 75% renal recovery

Shunt Nephritis
- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients

EULAR Recommendations for the Management of Systemic Lupus Erythematosus (SLE)  
Ann Rheum Dis 2008;67:195-205

Lupus Nephritis Recommendations

Monitoring: Renal biopsy, urine sediment analysis, proteinuria, and kidney function may have independent predictive ability for clinical outcome in therapy of lupus nephritis but need to be interpreted in conjunction. Changes in immunological tests (anti-dsDNA, serum C3) have only limited ability to predict the response to treatment and may be used only as supplemental information.

Treatment: In patients with proliferative lupus nephritis, glucocorticoids in combination with immunosuppressive agents are effective against progression to end-stage renal disease. Long-term efficacy has been demonstrated only for cyclophosphamide-based regimens, which are however associated with considerable adverse effects. In short- and medium-term trials, mycophenolate mofetil has demonstrated at least similar efficacy compared with pulse cyclophosphamide and a more favourable toxicity profile: failure to respond by 6 mo should evoke discussions for intensification of therapy. Flares following remission are not uncommon and require diligent follow-up.

End-stage renal disease: Dialysis and transplantation in SLE have long-term patient and graft-survival rates comparable with those observed in non-diabetic non-SLE patients, with transplantation being the method of choice.
HIV-Associated Renal Disease
1. direct nephrotoxic effect of HIV infection, antiretroviral drugs (e.g. tenofovir, indinavir) and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy (HIVAN)
   - histology: focal and segmental glomerular collapse with mesangial sclerosis, "collapsing FSGS"
   - tubular cystic dilatation and tubulo-reticular inclusions
   - clinical features: predominant in black men, heavy proteinuria, progressive renal insufficiency
   - prognosis: kidney failure within 1 yr without treatment
   - therapy: short-term, high dose steroids, ACEI, HAART

Infective Endocarditis
- manifests as mild form of acute nephritic syndrome with decreased serum complement
- S. aureus is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

Hepatitis B
- can result in membranous nephropathy, polycystic nodosa, membranoproliferative GN

Hepatitis C
- can result in membranoproliferative GN, cryoglobulinemia and membranous nephropathy

Syphilis
- can result in membranous GN

Tubulointerstitial Disease

Tubulointerstitial Nephritis (TIN)

Definition
- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

Signs and Symptoms
- manifestation of disease depends on site of tubule affected
  1. proximal tubule (e.g. multiple myeloma, heavy metals)
     - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, hypouricemia
     - proximal RTA (decreased bicarbonate absorption): Type II RTA
  2. distal tubule (e.g. amyloidosis, obstruction)
     - distal RTA (Type I RTA), usually hypokalemic
     - Na+ -wasting nephropathy
     - ± hyperkalemia leading to type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
  3. collecting duct (e.g. sickle cell anemia, analgesics, PCKD)
     - urinary concentrating defect leading to mild nephrogenic DI
     - polyuria

1. ACUTE TUBULOINTERSTITIAL NEPHRITIS (TIN)

Definition
- rapid (days to weeks) decline in renal function
- 10-20% of all acute kidney injury

Etiology
- hypersensitivity
  1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
- infections
  - bacterial pyelonephritis, Streptococcus, brucellosis, Legionella, CMV, EBV, toxoplasmosis, leptospirosis
- immune
  - SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia
  - idiopathic

Pathophysiology
- acute inflammatory cell infiltrates into renal interstitium
Signs and Symptoms
- AKI
- if hypersensitivity reaction: may see fever, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costo-vertebral angle (CVA) tenderness
- other signs and symptoms based on underlying etiology
- hypertension and edema are uncommon

Investigations
- mild, non-nephrotic range proteinuria and microscopic hematuria
- urine
  - sterile pyuria, WBC casts, mild proteinuria, hematuria
  - eosinophils if allergic interstitial nephritis
- blood
  - increased Cr and urea
  - eosinophilia if drug reaction
  - normal AG metabolic acidosis (RTA)
  - hypophosphatemia, hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive

Treatment
- treat underlying cause (e.g. stop offending medications, antibiotics if pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

Prognosis
- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely full renal recovery becomes

2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

Definition
- characterized by slowly progressive renal failure, moderate proteinuria and signs of abnormal tubule function

Etiology
- persistence or progression of acute TIN
- urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflex or UTI with obstruction
- nephrotoxins
  - exogenous
    - analgesics: NSAIDs (common), acetaminophen
    - cisplatin, lithium, cyclosporine, tacrolimus
    - heavy metals (lead, cadmium, copper), lithium, mercury, arsenic
    - radiation
    - chinese herbs
  - endogenous
    - hypercalcemia, hypokalemia, oxalate, uric acid nephropathy
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis
- immune: SLE, Sjögren’s, cryoglobulinemia, Goodpasture’s, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

Pathophysiology
- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

Signs and Symptoms
- tubular dysfunction (e.g. acidosis, electrolyte disturbances)
- progressive renal failure with azotemia and uremia
- dependent on underlying etiology

Treatment
- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders (Ca²⁺, PO₄³⁻) and anemia
Findings which Suggest Chronic Tubulointerstitial Nephritis
• normal AG metabolic acidosis
• hyperkalemia (out of proportion to degree of renal insufficiency)
• polyuria, nocturia
• partial or complete Fanconi’s syndrome
• urine: mild proteinuria, few RBCs and WBCs, no RBC casts
• ultrasound: shrunken kidneys with irregular contours

Acute Tubular Necrosis (ATN)

Definition
• abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
• GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

Etiology

Clinical Presentation
• typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
• urine: high FE\textsubscript{Na}, pigmented-granular casts

Complications
• hyperkalemia: can occur rapidly and cause serious arrhythmias
• metabolic acidosis, decreased Ca\textsuperscript{2+}, increased PO\textsubscript{4}\textsuperscript{3-}, hypoalbuminemia

Investigations
• blood: CBC, electrolytes, Cr, urea, Ca\textsuperscript{2+}, PO\textsubscript{4}\textsuperscript{3-}, blood gases
• urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for pigmented granular casts
• ECG
• abdominal ultrasound
• rule out other causes of pre-renal/post-renal azotemia and intrinsic AKI (GN, AIN, vasculitis)

Therapy
• largely supportive once underlying problem is corrected
• loop diuretics may help manage volume overload and reduce tubular metabolic requirements to allow for recovery (controversial)
• consider early dialysis in severe/rapidly progressing cases to prevent uremic syndrome

Prevention
• correct fluid balance before surgical procedures
• for patients with chronic renal disease requiring radiographic contrast:
  • give N-acetylcysteine 600-1200 mg PO bid day before and day of procedure, give intravenous isotonic fluid (either NaCl or NaHCO\textsubscript{3})
  • isotonic NaHCO\textsubscript{3} at 3 mL/kg over 1h before procedure and 1 mL/kg/h for 6 h post-procedure if not contraindicated
  • avoid giving diuretics, ACEI, cyclosporine on morning of procedure if possible
• use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency

Meta-analysis: Effectiveness of Drugs for Preventing Contrast-induced Nephropathy

Ann Intern Med 2006;144:284-294

Purpose: To determine the effectiveness of N-acetylcysteine, theophylline, fenoldopam, dopamine, iloprost, statin, furosemide, or mannitol on preventing nephropathy.

Study Selection: Only randomized, controlled trials that used these agents in patients receiving iodinated contrast.

Results: In the 41 RCTs included N-acetylcysteine (RR = 0.62 [0.44-0.88]) and Theophylline (RR = 0.49 [0.23-0.98]) reduced the risk of nephropathy more than saline alone. Furosemide increased the risk (RR = 3.27 [1.48-7.26]). Other agents did not affect risk of nephropathy.

Conclusion: N-acetylcysteine is more renoprotective than hydration alone.
Analgesic Nephropathies

1. Vasomotor Acute Kidney Injury (AKI)
   - normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
   - NSAIDs act by blocking cyclooxygenase enzyme, thereby preventing prostaglandin synthesis and causing renal ischemia
   - more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
   - clinically: develop prerenal azotemia within a few days of starting NSAID
   - treatment: discontinue NSAID, dialysis rarely needed

2. Acute Interstitial Nephritis (AIN)
   - fenoprofen (60%), ibuprofen, naproxen
   - may be associated with minimal change glomerulopathy and nephrotic range proteinuria
   - resolves eventually with discontinuation of NSAID, may require interval dialysis
   - short term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

3. Chronic Interstitial Nephritis
   - due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
   - seen in patients who also have emotional stress, psychiatric symptoms and GI disturbance
   - papillary necrosis
     - gross hematuria, flank pain, declining renal function
     - calyceal filling defect seen with IVP – “ring sign”
   - increased risk of transitional cell carcinoma of renal pelvis
   - good prognosis if discontinue analgesics

4. Acute Tubular Necrosis (ATN)
   - can be caused by acetaminophen
     - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
   - vascular endothelial damage can also occur
   - both direct toxicity and ischemia contribute to the tubular damage
   - renal function spontaneously returns to baseline within 1-4 wk
   - dialysis may be required during the acute episode of ingestion

5. Other Effects of NSAIDs
   - sodium retention (2° to reduced GFR)
   - hyperkalemia, HTN (2° to hyporeninemic hypoaldosteronism)
   - excess water retention (due to elimination of ADH – antagonistic effect of prostaglandins)

Systemic Disease with Renal Manifestation

Diabetes

- diabetic nephropathy: presence of microalbuminuria or overt nephropathy (i.e. macroalbuminuria) in patients with DM who lack indicators of other renal diseases
- most common cause of end-stage renal failure in North America
- 35-50% of patients with Type 1 DM will develop nephropathy, unknown percentage of Type 2
- at diagnosis up to 30% of patients with Type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
- microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
- once macroalbuminuria is established, renal function declines, 50% patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially Type 1 DM) and/or neuropathy (especially Type 2 DM)
- indication of possible nondiabetic cause of renal disease in patients with DM:
  - rising Cr with little/no proteinuria
  - lack of retinopathy or neuropathy (microvascular complications)
  - persistent hematuria (microscopic or macroscopic)
  - signs or symptoms of systemic disease
  - inappropriate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
  - family history of nondiabetic renal disease (e.g. PCKD, Alport’s)

DM is one of the causes of ESRD that does not result in small kidneys at presentation of ESRD. The others are amyloidosis, HIV nephropathy, PCKD and multiple myeloma.

Abnormal Urine ACR Values from 2008 Canadian Diabetes Association CPG
>2.0 mg/mmol in males
>2.8 mg/mmol in females

ACEI can cause hyperkalemia. Therefore, be sure to watch serum K⁺, especially if patient has DM and renal insufficiency.
DIABETIC RENAL COMPLICATIONS

1. Progressive Glomerulosclerosis
   - classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
   - more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

Table 13. Stages of Diabetic Progressive Glomerulosclerosis

<table>
<thead>
<tr>
<th>Stage 1</th>
<th>Stage 2</th>
<th>Stage 3</th>
<th>Stage 4</th>

<td>&lt;20% glomerular filtration surface area present</td>
</tr>
<tr>
<td></td>
<td>↑ mesangial matrix</td>
<td>Normal GFR</td>
<td>Sclerosis glomeruli</td>
</tr>
</tbody>
</table>

2. Accelerated Atherosclerosis
   - common finding
   - decreased GFR
   - may increase Angiotensin II production resulting in increased BP
   - increased risk of ATN secondary to contrast media

3. Autonomic Neuropathy
   - affects bladder leading to functional obstruction and urinary retention
   - residual urine promotes infection
   - obstructive nephropathy

4. Papillary Necrosis
   - Type 1 DM susceptible to ischemic necrosis of medullary papilla
   - sloughed papillae may obstruct ureter
   - can present as renal colic or with obstructive features ± hydronephrosis

2013 Canadian Diabetics Association Clinical Practice Guidelines on Chronic Kidney Disease in Diabetest

- screen for microalbuminuria with a random urine test for albumin to Cr ratio (ACR) and eGFR with a serum creatinine (using MRDR equation)
  - Type 1 DM: annually In post-pubertal individuals after 5 yr of diagnosis
  - Type 2 DM: at diagnosis, then annually
  - If eGFR >60 mL/min or ACR <2.0 mg/mmol: there is no CKD, re-screen in 1 yr
  - If urine ACR >20.0 mg/mmol: diagnose CKD.
  - If ACR <20.0 mg/mmol but >2.0 mg/mmol: order serum Cr for eGFR in 3 mo and 2 repeats of random urine ACRs over the next 3 mo. At 3 mo: If eGFR <60 mL/min or if >2/3 ACRs are >2.0 mg/mmol, diagnose CKD
  - if CKD diagnosed, ordered urine R-M and dipstick, if negative then diagnose CKD in Diabetes
  - with CKD in Diabetes: urine ACR and serum Cr (for eGFR) every 6 mo
  - delay screening if transient cause of albuminuria or low eGFR
  - evaluate for other causes of proteinuria, rule out nondiabetic renal disease
  - avoid unnecessary potential nephrotoxins (NSAIDs, aminoglycosides, dye studies)

Priorities in the Management of Patients with DM

1. vascular protection for all patients with diabetes
   - ACEI, antiplatelet therapy (as indicated)
   - BP control, glycemic control, lifestyle modification, lipid control

2. optimization of BP in patients who are hypertensive
   - treat according to hypertension guidelines

3. renal protection for DM patients with nephropathy (even in absence of HTN)
   - Type 1 DM: ACEI
   - Type 2 DM: CrCl >60 mL/min: ACEI or ARB – CrCl <60 mL/min: ARB
   - 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem, verapamil)
   - ACEI and ARB can be safely used together if needed for control of significant proteinuria (monitor for hyperkalemia and acute rise in Cr)
   - check serum Cr and K⁺ levels within 1 wk of initiating ACEI or ARB and at time of acute illness
   - serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
   - if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
   - consider holding ACEI, ARB and/or diuretic with acute illness and in women before becoming pregnant
   - consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive kidney function loss, unable to achieve BP targets or unable to stay on ACEI or ARB

Results: The number of outcome events was similar for telmisartan (n=1147) and ramipril (1150); HR 1.00, CI 0.92-1.09, but was increased with combination therapy (1233; HR 1.09, 1.01-1.18, p=0.037). The need for dialysis or doubling of serum Cr increased more slowly in the telmisartan group versus placebo or amlodipine. The difference in absolute mortality or secondary end point was not significant. Conclusion: Telmisartan conferred significant renoprotective benefits in patients with type 2 diabetes and nephropathy, independent of blood pressure lowering effects.
Scleroderma

- 50% of scleroderma patients have renal involvement (mild proteinuria, high Cr, HTN)
- histology: media thickened, "onion skin" hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
- 10-15% scleroderma patients have a "scleroderma renal crisis" (occurs in first few years of disease): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- renal involvement usually occurs early in the course of illness
- treatment: BP control with ACEI slows progression of renal disease

Multiple Myeloma

- see Hematology, H47
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms:
  - hypercalcemia
  - light chain cast nephropathy (LCCN, see below) or "myeloma kidney"
  - hyperuricemia
  - infection
  - secondary amyloidosis
  - monoclonal Ig deposition disease (MIDD)
  - diffuse tubular obstruction
- LCCN
  - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
  - proteinuria and renal insufficiency, can progress rapidly to kidney failure
- MIDD
  - deposits of monoclonal Ig in kidney, liver, heart and other organs
  - mostly light chains (85-90%)
  - causes nodular glomerulosclerosis (similar to diabetic nephropathy)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed unless malignancy is cured
  - solid tumours: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin's) or membranous GN (non-Hodgkin's)
  - renal cell carcinoma
  - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumours/mets: post-renal failure secondary to obstruction
  - 2a amyloidosis
  - radiotherapy (radiation nephritis)

Hypertension (HTN)

- HTN occurs in about 20% of population
- etiology classified as primary ("essential"); makes up 90% of cases) or secondary
- primary: hypertension due to other factors that cause renal disease (hypertensive nephrosclerosis) or worsen pre-existing renal disease
- secondary: diseases of renal parenchyma or renal vasculature that cause hypertension
### Hypertensive Nephrosclerosis

### Renovascular Hypertension

- see *Vascular Diseases of the Kidney, NP17*

### Renal Parenchymal Hypertension

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include
  - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  - ineffective sodium excretion with fluid overload

**Investigations**

- as well as investigations for renovascular HTN, additional tests may include
  - 24-h urinary estimations of Cr clearance and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy

**Treatment**

- most chronic renal disease is irreversible, but treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na+ restriction (88 mmol/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K+ and Cr) if there is significant proteinuria (>300 mg/d)

### Cystic Diseases of the Kidney

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population over 50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive) and acquired cystic kidney disease (in chronic hemodialysis patients)

### Adult Polycystic Kidney Disease

- autosomal dominant; at least 2 genes: PKD1 (chr 16p) and PKD2 (chr 4q)
- PKD1 (1:400), PKD2 (1:1000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant polycystin gene but accumulate a series of second 'somatic hits' precipitating the condition
- PKD1 encodes a protein that is responsible for cell-cell and cell-matrix interaction and sensing fluid flow by associating with cilia
- PKD2 encodes a protein that is a Ca2+ permeable nonselective cation channel that associates with cilia and is thought to control intracellular Ca2+ in response to flow
- defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth
- extrarenal manifestations: most common; multiple asymptomatic hepatic cysts (33%), cerebral aneurysm (10%), diverticulosis and mitral valve prolapse (25%)?
- polycystic liver disease rarely causes liver failure
- less common: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta
Signs and Symptoms
- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain
- hematuria (microscopic frequently initial sign, gross)
- nocturia (urinary concentrating defect)
- rarely extra-renal presentation (e.g. ruptured berry aneurysm, diverticulitis)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- ± palpable kidneys

Common Complications
- urinary tract and cyst infections, HTN, CRF, nephrolithiasis (5-15%), flank and chronic back pain

Clinical Course
- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10 times normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

Investigations
- radiographic diagnosis: best accomplished by renal U/S (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdo with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- gene linkage analysis for PKD1 for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)

Treatment
- goal: to preserve renal function by prevention and treatment of complications
- educate patient and family about disease, its manifestations and inheritance pattern
- genetic counselling: transmission rate 50% from affected parent
- prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
- TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
- adequate hydration to prevent stone formation
- avoid contact sports due to greater risk of injury to enlarged kidneys
- screen for cerebral aneurysms if family history of aneurysmal hemorrhages
- monitor blood pressure and treat hypertension with ACEI
- dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
- may require nephrectomy to create room for renal transplant

Medullary Sponge Kidney
- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney
- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP, characteristic radial pattern (“bouquet of flowers”), “swiss cheese” appearance on morphology
- treat UTIs and stone formation as indicated
- does not result in renal failure

Autosomal Recessive Polycystic Kidney Disease
- 1:20,000 incidence
- prenatal diagnosis by enlarged kidneys
- perinatal death from respiratory failure
- patients who survive perinatal period develop CHF, HTN, chronic kidney disease
- treated with kidney and/or liver transplant
**Acute Kidney Injury (AKI)**

**Definition**
- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as Acute Renal Failure (ARF)

**Clinical Features**
- azotemia (increased BUN, Cr)
- abnormal urine volume (anuria, oliguria, polyuria)

---

**Approach to AKI**

**Investigations**
- blood: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca\(^{2+}\), PO\(_4\)^{3-}
- urine volume, C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- Foley catheterization (rule out bladder outlet obstruction)
- fluid challenge (i.e. fluid bolus to rule out most prerenal causes)
- imaging: abdo U/S (assess kidney size, hydronephrosis, post-renal obstruction)
- indications for renal biopsy
  - diagnosis is not certain
  - prerenal azotemia or ATN is unlikely
  - oliguria persists >4 wk

**Treatment**
1. preliminary measures
   - pre-renal
     - correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, i.e. CHF)
   - renal
     - address reversible renal causes: d/c nephrotoxic drugs, treat infection, and optimize electrolytes
   - post-renal
     - consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
     - treat with Foley catheter, indwelling bladder catheter, nephrostomy, stenting
2. treat complications
   - fluid overload
   - NaCl restriction
   - high dose loop diuretics
   - hyperkalemia (refer to Approach to Hyperkalemia, NP13)

---

**Clues to Pre-Renal Etiology**
- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes
- Increased (urea) >> Increased (Cr)
- Urine Na\(^+\) <10-20 mmol/L
- Urine osmolality >500 mOsm/kg
- Fractional excretion of Na\(^+\) <1%

**Clues to Renal Etiology**
- Appropriate clinical context
- Urinalysis positive for casts: Pigmented granular – ATN, WBC – AIN, RBC – GN

**Clues to Post-Renal Etiology**
- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis

**Drugs Implicated in Pre-Renal Azotemia**
- Anti-hypertensives
- Diuretics
- NSAIDs
- ACEI/ARBs
**Chronic Kidney Disease (CKD)**

**Definition**
- progressive and irreversible loss of kidney function
- abnormal markers (Cr, urea)
  - GFR <60 mL/min for >3 mo or
  - kidney pathology seen on biopsy or
  - decreased renal size on U/S (kidneys <9 cm)
- clinical features of chronic kidney disease
  - volume overload and hypertension
  - electrolyte and acid-base balance disorders (e.g. metabolic acidosis)
  - uremia

**Table 15. Stages of Chronic Kidney Disease (KDIGO, 2013)**

**Prognosis**
- high morbidity and mortality in patients with sustained AKI and multi-organ failure

**Management of Chronic Kidney Disease**

- **diet**
  - protein restriction with adequate caloric intake limits endogenous protein catabolism
  - K⁺ restriction (40 mmol/d)
  - Na⁺ and water restriction
  - PO₄³⁻ restriction (1 g/d)
  - avoid extra-dietary Mg²⁺ (i.e. antacids)
- **medical**
  - treatment of secondary hyperparathyroidism
  - calcium supplements (e.g. TUMS®) treats hypocalcemia when given between meals and binds phosphate when given with meals
  - consider calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic
  - sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
  - vitamin D analogues are being introduced in the near future
  - cinacalcet for hyperparathyroidism (sensitizes parathyroid to Ca²⁺, decreasing PTH)
  - sodium bicarbonate for metabolic acidosis
  - erythropoietin injections (Hct <30%) for anemia; target Hct 33-36%
  - ACEI for hypertension (target 130/80 or less), loop diuretics when GFR <25 mL/min
  - statins for dyslipidemia
- adjust dosages for renally excreted medications (avoid nephrotoxic medications)
- dialysis (hemodialysis, peritoneal dialysis)
- renal transplantation

**Incidence of Etiologies of Chronic Kidney Disease (CKD)**

- Diabetes: 42.9%
- Hypertension: 26.4%
- Glomerulonephritis: 9.9%
- Other/Unknown: 7.7%
- Interstitial nephritis/Pyelonephritis: 4.0%
- Cystic/Hereditary/Congenital: 3.1%
- Secondary GN/Vasculitis: 2.4%

**Management of Complications of CKD**

- **NEPHRON**
  - N = Low-nitrogen diet
  - E = Electrolytes: monitor K⁺
  - P = pH: metabolic acidosis
  - H = Hypertension
  - R = RBCs: manage anemia with erythropoietin
  - O = Osteodystrophy: give calcium between meals (to increase Ca²⁺) and calcium with meals (to bind and decrease PO₄³⁻)
  - N = Nephrotoxins: avoid nephrotoxic drugs (ASA, gentamicin) and adjust doses of renally excreted medications

**Renin Angiotensin System Blockade and Cardiovascular Outcomes in Patients with Chronic Kidney Disease and Proteinuria: A Meta-analysis**

- Am Heart J 2008;155:791-805
- Purpose: To evaluate the role of renin angiotensin system (RAS) blockade in improving cardiovascular CV outcomes in patients with chronic kidney disease (CKD).
- Study Selection: Randomized controlled trials that analyzed CV outcomes in patients with CKD/proteinuria treated with RAS blockade (ACEI/ARB) compared to placebo and control (β-blockers, calcium-channel blockers and other antihypertensive-based therapy) therapy in the study.
- Results: Twenty-five trials (N = 45758) were included. Compared to placebo, RAS blockade reduced the risk of heart failure in patients with diabetic nephropathy. In patients with non-diabetic CKD, RAS blockade decreased CV outcome compared to control therapy.
- Conclusions: RAS blockade reduced CV outcomes in diabetic nephropathy as well as non-diabetic CKD.
Prevention of Progression
• as above
• control of hypertension, diabetes, cardiovascular risk factors (e.g. smoking cessation)
• avoid nephrotoxins
• address reversible causes of AKI

Renal Failure

Presentation of Renal Failure

1. Volume Overload
• due to increase in total body Na⁺ content
• signs: weight gain, HTN, pulmonary or peripheral edema

2. Electrolyte Abnormalities
• high
  • K⁺ (decreased renal excretion, increased tissue breakdown)
  • PO₄³⁻ (decreased renal excretion, increased tissue breakdown)
  • Ca²⁺ (rare; happens during recovery phase after rhabdomyolysis-induced acute kidney injury or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
  • uric acid
• low
  • Na⁺ (failure to excrete excessive water intake)
  • Ca²⁺ (decreased Vit D activation, hyperphosphatemia, hypoalbuminemia)
  • HCO₃⁻ (especially with sepsis or severe heart failure)

3. Uremic Syndrome
• manifestations result from retention of urea and other metabolites as well as hormone deficiencies

Signs and Symptoms of Renal Failure

Figure 18. Signs and symptoms of renal failure
Complications
- CNS: decreased LOC, stupor, seizure
- CVS: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- GI: peptic ulcer disease, gastrroduodenitis, AVM
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
- endocrine:
  - decreased testosterone, estrogen, progesterone
  - increased FSH, LH
- metabolic:
  - renal osteodystrophy: secondary increased PTH due to decreased Ca\(^{2+}\), high PO\(_4\)\(^{3-}\) and low active vitamin D
  - osteitis fibrosa cystica
  - hypertriglyceridemia, accelerated atherogenesis
  - decreased insulin requirements, increased insulin resistance
- dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular Ca\(^{2+}\) deposition)

Renal Replacement Therapy

Dialysis

Indications for Dialysis in Chronic Renal Failure

*Unresponsive to medications

- **h*emodialysis**: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  - available as intermittent (e.g. three times per week), continuous (CVVHD) or sustained low efficiency (SLED)
  - can be delivered at home or in-centre, nocturnal
  - vascular access can be achieved through a central line, an artificial graft or an arterio-venous fistula
  - patients with chronic kidney disease should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >350 µmol/L (>4.0 mg/dL), or within 1 yr of an anticipated need
- **peritoneal dialysis**: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  - available as continuous ambulatory (CAPD; four exchanges per day) or cyclic (CCPD; machine carries out exchanges overnight)
  - refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

How to Write Dialysis Orders
(MUST BE INDIVIDUALIZED)
- Filter Type (e.g. F800)
- Length (e.g. 4h 3 times/wk or 2h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- Na\(^+\) 140 (can be adjusted by starting at 155 and “ramping” down to minimize cramping)
- K\(^+\) [based on serum (K\(^+\))]
  - Serum K\(^+\) Dialysate
    - 4-6 1.5
    - 3.5-4 2.5
    - <3.5 3.5
  - Ca\(^{2+}\) 1.25
  - HCO\(_3\) 40
  - Heparin (none, tight (500 U/h) or full (1000 U/h))
  - IV fluid to support BP (e.g. N/S)

### Renal Transplantation

- Preferred modality of RRT, best way to reverse uremic signs and symptoms
- Provides maximum replacement of GFR
- Only therapy shown to improve survival in patients with ESRD
- Native kidneys usually left in situ
- 2 types: deceased donor, living donor (related or unrelated)
- Kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- 1 yr renal allograft survival rates ≥90%

**Complications**

- Leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
- #1 cause of mortality in transplanted patients is cardiovascular disease
- Immunosuppressant drug therapy: side effects include infections, malignancy (skin, Kaposi’s sarcoma, post-transplant lymphoproliferative disorder)
- Acute rejection: graft site tenderness, rise in Cr, oliguria, ± fever, although symptoms are uncommon
- De novo glomerulonephritis (usually membranous)
- New-onset diabetes mellitus (often due to prednisone use)
- Cyclosporine or tacrolimus nephropathy (refer to Small Vessel Disease, NP18)
- Chronic allograft nephropathy
  - Early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
  - Immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset diabetes)
- Transplant glomerulopathy from antibody injury causes nephrotic proteinuria
- CMV (cytomegalovirus) infection and other opportunistic infections usually occur between 1 and 6 mo post-transplant
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss

**When to Initiate Dialysis**

CrCl <20 mL/min
- Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula

CrCl <15 mL/min
- Weigh risk and benefits for initiating dialysis

CrCl <10 mL/min
- Dialysis should be initiated

**NOTE**
- Cockcroft-Gault equation (or Modification of Diet in Renal Disease equation) should be used to measure kidney function
- Monitor for uremic complications
- Significant benefits in quality of life can occur if dialysis started before CrCl <15 mL/min
- It is unclear whether patients who start dialysis early have increased survival
- A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

**Commonly Used Immunosuppressive Drugs**

- Calcineurin inhibitors
- Calcitriol
- Antiproliferative medications
  - Mycophenolate Mofetil
  - Azathioprine
- Other agents
  - Sirolimus
  - Prednisone
- Anti-lymphocyte antibodies
  - Thymoglobulin
  - Basiliximab

**Survival Among Nocturnal Home Hemodialysis Patients Compared to Kidney Transplant Recipients**

**Recipients**

- Retrospective, matched cohort with 4-5 yr average follow up.
- Population: 117 nocturnal home dialysis (NHD) patients (mean age 46, 68% white) were matched to 533 deceased donor transplant (DTX) patients and 533 live donor (LTX) transplant patients (1:3:3 ratio).
- Intervention: Nocturnal home dialysis versus live or deceased donor transplant.
- Outcome: Primary outcome was all cause mortality
- Results: No significant difference in survival or hazard ratio between NHD and DTX. Significant survival benefit for patients undergoing LTX versus NHD. Significant mortality hazard ratio reduction with LTX (0.51) with no difference in hazard ratio for DTX versus NHD reference.
- Conclusion: NHD has comparable mortality to DTX, but is inferior to LTX.

The Neurological Exam

General Exam and Mental Status

- **vitals**: pulse (especially rhythm), BP, temperature
- **H&N**: meningismus, head injury/bruises, (signs of basal skull fracture: Battle’s sign, raccoon eyes, hemotympanum, rhinorrhea), tongue biting
- **CVS**: carotid bruits, heart murmurs
- **mental status**: orientation (person, place, time), LOC (GCS)
  - GCS/15 = Motor/6, Verbal/5 (T = intubated), Eyes/4
- **cognition**:
  - Folstein MMSE – /30 (≤ 24 indicative of dementia)
  - MoCA – /30 (≥ 26 is considered normal)
- **clock drawing**

Cranial Nerves Exam

- **olfactory (CNI)**: odour sensation (test each nostril separately)
- **optic (CNII)**
  a. visual acuity: test each eye individually using best corrected vision
  b. visual fields
  c. pupil: direct and consensual pupillary reaction (afferent limb), accommodation, swinging flashlight test (see Relative Afferent Pupillary Defect, Ophthalmology, OP33)
  d. fundoscopy: optic disc edema, optic disc pallor, venous pulsations, hemorrhages
- **extra ocular movements (EOM)**
  a. **oculomotor (CNIII)**: levator palpebrae superioris, medial rectus, superior rectus, inferior rectus, inferior oblique, efferent limb of pupillary light response
  b. **trochlear (CNIV)**: superior oblique
  c. **abducens (CNVI)**: lateral rectus
- **trigeminal (CNV)**
  a. sensory: V1 (above supraorbital ridge), V2 (buccal area), V3 (mandible), corneal reflex (afferent)
  b. motor: temporalis, masseter, pterygoids, jaw jerk reflex
- **facial (CNVII)**
  a. sensorimotor: muscles of facial expression, hyperacusis (stapedius), corneal reflex (afferent)
  b. visceral sensory: taste of anterior 2/3 of tongue
  c. visceral motor: salivary and lacrimal glands
- **vestibulocochlear (CNVIII)**
  a. vestibular: nystagmus, caloric reflexes
  b. cochlear: Rinne, Weber
- **glossopharyngeal (CNIX) and vagus (CNX)**: palatal elevation, gag reflex, vocal cord function, swallowing, taste of posterior third of tongue
- **accessory (CNXI)**: trapezius and sternocleidomastoid strength
- **hypoglossal (CNXI)**: tongue muscle bulk, fasciculations, strength

Motor Exam

- **bulk**: atrophy, asymmetry
- **abnormal movements**: tremors, chorea, dystonia, dyskinesia, hemiballismus, myoclonus, athetosis, tics, fasciculations
- **abnormal posturing**: decerebrate, decorticate
- **tone**: hypotonia (flaccid), hypertonia (spasticity, rigidity, paratonia), cogwheeling
- **strength**
- **reflexes**: deep tendon reflexes, abdominal reflexes, primitive reflexes, Babinski, Hoffman, clonus

**Upper Motor Neuron Tests**

- **Babinski Reflex**: "Up-going" big toe ± fanning of toes indicates an UMN lesion.
- **Hoffman Reflex**: Flexion of IP joint of the thumb when tapping the nail of the index or ring finger may indicate an UMN lesion if asymmetrical.
- **Pronator Drift**: Patients are unable to maintain arm extension and supination in an UMN lesion.

Table 3. Approach to Strength Testing of Radiculopathies versus Peripheral Neuropathies

How to use this table: For each nerve root, learn two (or more) peripheral nerves (and their associated muscles/movements). In radiculopathies, all associated peripheral nerves (and their movements) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its movement) will be impaired, sparing the other nerve. Especially useful peripheral nerve “pairs” are bolded for emphasis.

Sensory Exam

- **primary sensation**
  - spinothalamic tract: pain and temperature
  - dorsal column: proprioception and vibration
- **cortical sensation**
  - graphesthesia, stereognosis, extinction, 2-point discrimination
Coordination Exam and Gait

• coordination exam
  • finger-to-nose, heel-to-shin, rapid alternating movements, “scanning” speech
• stance and gait
  • gait: antalgic, hemiplegic, ataxic, apraxic, festination, foot drop, broad-based
tandem gait (heel-to-toe walking)
  • Romberg test
  • pull test for retropulsion

Basic Anatomy Review

Figure 1. Brainstem (axial view)

Figure 2. Brainstem (posterior view)

A slow or uncoordinated rapid alternating movement can also be a sign of subtle weakness or Parkinsonism.

Romberg Test
Stable with eyes open and closed = normal.
Stable with eyes open, falls with eyes closed = +ve Romberg, suggesting loss of joint position sense.
Internal capsule

Upper motor neurons in motor cortex

Within 1-2 spinal levels of their entry, axons of first order neurons synapse onto second order neurons, whose axons then decussate before ascending as the spinothalamic tract.

**Figure 3.** Discriminative touch pathway (dorsal column) from body

**Figure 4.** Spinothalamic tract from body

**Figure 5.** Discriminative touch pathway (dorsal column) from face

**Figure 6.** Spinothalamic tract pathway from face

**Figure 7.** Corticospinal motor pathway
Figure 8. Sympathetic and parasympathetic pathway

Figure 9. Dermatome map

Myotomes
C5 – Shoulder abduction/elbow flexion
C6 – Wrist extensors
C7 – Elbow extension
C8 – Squeeze hand
T1 – Abduct fingers
T2-9 – Intercostal (abdominal reflexes)
T9-10 – Upper abdominals
T11-12 – Lower abdominals
L2 – Flex hip
L3 – Hip adduction
L4 – Knee extension and ankle dorsiflexion
L5 – Ankle dorsiflexion and big toe extension
S1 – Plantarflexion
Lumbar Puncture

Indications
• diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, Guillain-Barré, vasculitis), subarachnoid hemorrhage (if CT negative), CNS neoplasm (neoplastic meningitis)
• therapeutic: to administer anesthesia, chemotherapy, contrast media; to decrease intracranial pressure (pseudotumour cerebri, normal pressure hydrocephalus)

Contraindications
• mass lesion causing increased intracranial pressure (ICP) – could lead to cerebral herniation
  ▪ require CT first
• infection over lumbar puncture (LP) site/suspected epidural abscess
• low platelets (<50,000) or treatment with anticoagulation (high INR or aPTT)
• uncooperative patient

Complications
• tonsillar herniation
• post-LP headache (5-40%): worse when upright, better supine; generally onset within 24 h
  ▪ prevention: smaller gauge (i.e. 22) needle, reinsert stylet prior to needle removal, blunt-ended needle
  ▪ symptomatic treatment: caffeine and sodium benzoate injection
  ▪ corrective treatment: blood patch (autologous)
• spinal epidural hematoma
• infection

What to send LP for
• tube #1: cell count and differential: RBCs, WBCs and differential
  ▪ xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF)
• tube #2: chemistry: glucose (compare to serum glucose) and protein
• tube #3: microbiology: Gram stain and C&S
  ▪ specific tests depending on clinical situation/suspicion
  ▪ viral: PCR for herpes simplex virus (HSV) and other viruses
  ▪ bacterial: polysaccharide antigens of H. influenzae, N. meningitidis, S. pneumoniae
  ▪ fungal: Cryptococcal antigen, India ink stain (cryptococcus), culture
  ▪ TB: acid-fast stain, TB culture, TB PCR
• tube #4: cytology: for evidence of malignant cells
• tube #5: cell count: compare RBC count to that of tube #1
  ▪ note: tube 4 or 5 can be sent for repeat cell count

| Table 4. Lumbar Puncture Interpretation (Normal vs. Various Infectious Causes) |
|---------------------------------|-----------------|-----------------|-----------------|
| Condition                       | Colour          | Protein         | Glucose         | Cells            |
| NORMAL                          | Clear           | <0.45 g/L       | 60% of serum glc or >3.0 mmol/L | 0-5 WBC, 0 RBC, 0 PMNs |
| INFECTIOUS                      |                 |                 |                 |                  |
| Viral infection                 | Clear or opalescent | Normal or slightly increased <0.45-1 g/L | Normal | <1000x10⁵/L Lymphocytes mostly, some PMNs |
| Bacterial infection            | Opalescent yellow, may clot | >1 g/L | Decreased (<25% serum glc or <2.0 mmol/L) | >1000x10⁵/L PMNs |
| Granulomatous infection        | Clear or opalescent | Increased but usually <5 g/L | Decreased (usually <2.0-4.0 mmol/L) | <1000x10⁵/L Lymphocytes |

Approach to Common Presentations

Weakness

Approach
• mode of onset: abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (hereditary, degenerative, endocrinologic, neoplastic)
• course: worse at onset (vascular), progressive (neoplastic, degenerative, infective), episodic (vascular, inflammatory), activity dependent (NMJ, muscular)
• pattern: objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
• associated symptoms: sensory symptoms, cortical symptoms, spinal symptoms (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
• history: family history, developmental history, medications, risk factors, recent/preceding exposures
• investigations for LMN: NCS/EMG
• investigations for UMN: imaging (brain and/or spinal cord)
Differential Diagnosis
• objective muscle weakness
  ▪ generalized:
    • myopathy (muscular dystrophy, polymyositis, vasculitis, collagen vascular, HIV, CMV, influenza, steroids, statins, alcohol, hypothroidism, Cushings syndrome, electrolyte disorders)
    • NMJ (MG, botulism, LEMS, organophosphate poisoning)
  ▪ localized:
    • UMN (leukodystrophy, vasculitis, abscess, brain tumour, vitamin B₁₂ deficiency, MS, stroke)
    • anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic, lead toxicity)
    • peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
• no objective muscle weakness
  ▪ chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  ▪ depression, deconditioning
• if loss of passive motion, consider intra-articular, peri-articular or extra-articular causes

Numbness/Altered Sensation

Approach
• positive sensory symptoms: parasthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
• negative sensory symptoms: hypoesthesia/anaesthesia = numbness, diminution or absence of feeling
• determine distribution of sensory loss: nerve root vs. peripheral nerve
• investigations: NCS, vitamin B₁₂ levels, imaging based on associated findings

Differential Diagnosis
• cerebral: stroke, demyelination, tumour
  ▪ associated symptoms: hemiplegia, aphasia, apraxia
• brainstem: stroke, demyelination, tumour
  ▪ associated symptoms: diplopia, vertigo, dysarthria, dysphagia
• spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B₁₂ deficiency, disc lesion
  ▪ associated symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern)
• neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, B₁₂ deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid

Cranial Nerve Deficits

CN I: Olfactory Nerve

Clinical Features
• absence of sense of smell associated with a loss of taste

Differential Diagnosis
• nasal: physical obstruction
  ▪ heavy smoking, chronic rhinitis, sinusitis, neoplasms, sepal deformity, choanal atresia, vestibular stenosis, foreign body
• olfactory neuroepithelial: destruction of receptors or their axon filaments
  ▪ influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy)
• central: lesion of olfactory pathway
  ▪ Kallmann’s syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeal inflammation, meningioma, aneurysm, PD, stroke, MS
• endocrine/metabolic
  ▪ DM, adrenal hypo/hyperfunction, pseudohypoparathyroidism, hypothroidism, renal/liver failure, vitamin deficiency

CN II: Optic Nerve

• see Neuro-Ophthalmology, N11
CN III: Oculomotor Nerve

Clinical Features
- ptosis, resting eye position is “down and out” (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation and depression

Differential Diagnosis
- PCOM aneurysm: early mydriasis, then CN III palsy
- cavernous sinus (internal carotid aneurysm, meningioma, sinus thrombosis): associated with deficits in other CNs near the cavernous sinus (see Figure 11)
- ischemia of CNIII (DM, temporal arteritis, HTN, atherosclerosis): pupil sparing CN III palsy
- midbrain lesion: complete unilateral CNIII palsy with bilateral weakness of the superior rectus and ptosis with contralateral pyramidal signs ± mydriasis
- orbital lesion: associated with optic neuropathy, chemosis, proptosis
- other (inflammatory, infection, neoplasia, uncal herniation, trauma)

**Figure 11. Cavernous sinus (coronal view)**

CN IV: Trochlear Nerve

Clinical Features
- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

Differential Diagnosis
- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumour, granuloma)

CN V: Trigeminal Nerve

Clinical Features
- ipsilateral facial numbness, weakness of muscles of mastication (V3 only) with pterygoid deviation towards the side of the lesion

Differential Diagnosis
- brainstem (ischemia, tumour, syringobulbia, demyelination)
- peripheral (tumour, aneurysm, chronic meningitis, metastatic infiltration of nerve)
- trigeminal ganglion (acoustic neuroma, meningioma, fracture of middle fossa)
- cavernous sinus (carotid aneurysm, meningioma, sinus thrombosis)
- trauma
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

CN VI: Abducens Nerve

Clinical Features
- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze

Differential Diagnosis
- pons (infarction, hemorrhage, demyelination, tumour): associated with facial weakness and contralateral pyramidal signs
- tentorial orifice (compression, meningioma, trauma): false localizing sign of increased ICP
- cavernous sinus (carotid aneurysm, meningioma, sinus thrombosis)
- ischemia of CN VI (DM, temporal arteritis, HTN, atherosclerosis)
- congenital (Duane’s syndrome)
CN VII: Facial Nerve

Clinical Features
- LMN lesion: ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- UMN lesion: contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)
- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

Differential Diagnosis
- idiopathic = Bell's Palsy, 80-90% of cases (see Otolaryngology, OT22)
  - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- other: temporal bone fracture, EBV, Ramsay-Hunt (HSV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, lyme meningitis, HIV

CN VIII: Vestibulocochlear Nerve

- see Otolaryngology, OT12

CN IX: Glossopharyngeal Nerve

Clinical Features
- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue
- absent gag reflex and dysphagia

Disorders
- glossopharyngeal neuralgia: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
  - treated with carbamazepine or surgical ablation of CN IX

CN X: Vagus Nerve

Clinical Features
- oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
- neuromuscular causes of dysphagia:
  - CNS: stroke, cerebral palsy, tumour, trauma, PD, AD, MS
  - CN: DM, laryngeal nerve palsy, polio, ALS
  - myopathic/NMJ: dermatomyositis, polymyositis, MG, sarcoidosis
- other causes of dysphagia: see Gastroenterology, G8
- dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance
CN XI: Accessory Nerve

Clinical Features
• LMN lesion: paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
• UMN lesion: paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

CN XII: Hypoglossal Nerve

Clinical Features
• LMN lesion: tongue deviation towards lesion; ipsilateral tongue atrophy and fasciculations (if chronic)
• UMN lesion: tongue deviation away from lesion; absence of atrophy and fasciculations

NEURO-OPHTHALMOLOGY

Abnormalities of Vision
• see Ophthalmology, OP3

Acute Visual Loss
• see Ophthalmology, OP3

Optic Neuritis
• see Optic Disc Edema below, Multiple Sclerosis, N46

Anterior Ischemic Optic Neuropathy
• see also Optic Disc Edema, below
• non-arteritic (NAION): due to atherosclerosis
• arteritic (AION): due to giant cell arteritis (see Rheumatology, RH20)

Amaurosis Fugax
• see Ophthalmology, OP37 and Stroke, N43

Central Retinal Vein Occlusion (CRVO)
• see Ophthalmology, OP24

CN XI is vulnerable to damage during neck surgery.

Ipsilateral tongue paralysis with contralateral hemiparesis/sensory symptoms is pathognomonic for a medial medullary infarction.

If you suspect the diagnosis of giant cell arteritis do not wait for biopsy results. Begin treatment immediately!

NAION can be caused by use of Sildenafil (Viagra®) in rare cases.

</tr>
</tbody>
</table>

Abnormalities of Eye Movements

Disorders of Gaze

Pathophysiology
- horizontal gaze: FEF → contralateral PPRF (midbrain/pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

Clinical Features
- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
  - can be overcome with doll’s eye maneuver
- unilateral lesion in the PPRF → eyes deviate away from the lesion
  - cannot be overcome with doll’s eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

Etiology
- common: infarcts (frontal or brainstem), MS, tumours

A lesion in a cerebral hemisphere causes eyes to “look away” from the hemiplegia, and to look towards the lesion.

A lesion in the brainstem causes the eyes to “look toward” the side of the hemiplegia, and to look away from the lesion.
**Internuclear Ophthalmoplegia (INO)**

**Pathophysiology**
- results from a lesion in MLF which disrupts coordination between CN VI nucleus in pons and the contralateral CN III nucleus in midbrain → disrupts conjugate horizontal gaze

**Clinical Features**
- horizontal diplopia on lateral gaze, oscillopsia
- on gaze away from the side of the lesion (see Figure 14)
  - ipsilateral adduction defect
  - contralateral abduction nystagmus
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

**Etiology**
- common: MS, brain stem infarct

**Investigations**
- MRI

---

**Diplopia**

**Etiology – Monocular**
- mostly due to relatively benign optical problems (refractive error, cataract) or functional

**Etiology – Binocular** (due to ocular misalignment)
- muscle
  - Graves’ ophthalmopathy
  - EOM restriction/entrapment
- neuromuscular junction
  - MG (see Myasthenia Gravis, N32)
  - cranial nerve palsy (see Cranial Nerve Deficits, N8)
  - INO (see Internuclear Ophthalmoplegia, above)
- other
  - orbital trauma (orbital floor fracture), tumour, infection, inflammation
  - Miller-Fisher variant of GBS
  - Wernicke’s encephalopathy
  - leptomeningial disease

**Approach to Diplopia**
- monocular vs. binocular
- horizontal vs. vertical vs. oblique diplopia
- direction of gaze that exacerbates diplopia
- corrective head movements

**Workup**
- may observe isolated 4th or 6th nerve palsy for a few weeks, but workup if persistent or other symptoms develop
- indications for neuroimaging:
  - bilateral or multiple nerve involvement
  - severe sudden onset headache (rule out aneurysm)

**Nystagmus**

- **definition**: rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
- direction of nystagmus is labelled by the **rapid** component of the eye movement
- can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological
### Abnormalities of Pupils

- see Ophthalmology, OP30

### Seizure Disorders and Epilepsy

#### Seizure

**Definitions**
- seizure: transient neurological dysfunction caused by excessive activity of cortical neurons, resulting in paroxysmal alteration of behaviour and/or EEG changes
- epilepsy: chronic condition characterized by two or more unprovoked seizures

#### Classification

![Classification of seizures](image)

**NOTE:** seizures can also be classified using age of onset [childhood/adolescence, adulthood/late (i.e. > age 30)], setting (sleep, upon awakening), EEG (focal, generalized)

#### Signs and Symptoms

- generalized seizures (decreased LOC)
  - tonic-clonic [grand mal, generalized tonic-clonic (GTC)]:
    - prodrome of unease or irritability hours to days before the episode
    - tonic ictal phase: muscle rigidity
    - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
    - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours
  - absence (petit mal): usually only seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
  - tonic: muscle rigidity in flexion or extension
  - clonic: repetitive rhythmic jerking movements
  - myoclonic: sporadic contractions localized to muscle groups of one or more extremities
  - atonic: loss of muscle tone leading to drop attack

#### Medical Emergency!

**Status epilepticus** can cause irreversible brain damage without treatment.

**Stroke** is the most common cause of late-onset (>50 yr of age) seizures, accounting for 50-60% of cases.

**Seizures and Dementia**

Neurodegenerative diseases can underlie seizures. Conversely, seizures can be a cause of dementia.
• partial seizures
  ▪ simple or complex can secondarily generalize, or simple → complex → generalized seizures
  ▪ simple (preserved LOC)
    • motor: postural, phonoitory, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    • sensory: unusual sensations affecting vision, hearing, smell, taste or touch
    • autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
    • psychiatric: symptoms rarely occur without impairment of consciousness and are more commonly complex partial
  ▪ complex (altered LOC)
    • patient may appear to be awake but with impairment of awareness
    • classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing and other stereotypic movements
    • other forms: dysphasic, dysmnesic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness

*Pseudoseizures do not rule out seizures (not uncommon to present with both)

Investigations
• CBC, electrolytes, fasting blood glucose, Ca²⁺, Mg²⁺, ESR, Cr, liver enzymes, CK, prolactin
• also consider toxicology screen, EtOH level, AED level (if applicable)
• CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
• LP (if fever or meningismus)
• EEG
Treatment
- avoid precipitating factors
- indications for medical therapy (anticonvulsants): 2 or more unprovoked seizures, known organic brain disease, EEG with epileptiform activity, first episode of status epilepticus, abnormal neurologic examination or findings on neuroimaging
- psychosocial issues: stigma of seizures, education of patient and family, status of driver’s license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- consider surgical treatment if focal and refractory

Status Epilepticus
- definition: unremitting seizure of greater than 5 min; or successive seizures without return to a baseline state
- complications: anoxia, cerebral ischemia and cerebral edema, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- initial measures: ABCs, vitals, monitors, fingerprick glucose (STAT), ECG, nasal O2, IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
- bloodwork: electrolytes, Ca²⁺, Mg²⁺, PO₄³⁻, glucose, CBC, toxicology screen, EtOH level, AED levels
- focused history: onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history
- physical exam (once seizures controlled): LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (r/o injuries)

Figure 17. Status epilepticus treatment algorithm

Antiepileptic Drugs (AED)
- generalized-onset and partial-onset seizures: felbamate, lamotrigine, levetiracetam, refrinamide, topiramate, valproate, zonisamide
- partial seizures (simple partial, complex partial and secondarily generalized seizures): carbamazepine, gabapentin, lacosamide, oxcarbazepine, phenobarbital, phenytoin, pregabalain, primidone, tiagabine, vigabatrin (note: these drugs may exacerbate generalized seizures)
- absence seizures: ethosuximide

Dementia

• see Psychiatry, PS20

Definition
• an acquired, generalized and (usually) progressive impairment of cognitive function (i.e. memory, recall, orientation, language, abstraction) associated with impairment in activities of daily living (i.e. planning, shopping, food preparation, difficulties with finances)
• effect on content, but not level of consciousness
• see Psychiatry, PS20 for DSM-IV diagnostic criteria
• see Geriatric Medicine, GM5
• differentiated from Mild Cognitive Impairment (MCI) by the extent to which the impairment affects ADLs
  • MCI represents an intermediate stage between dementia and normal aging
  • by definition, IADLs are not affected in MCI

Epidemiology
• 15% of those >65 yr of age have dementia
• <5% reversible

Etiology
• see Table 10 for common causes of dementia
• see Table 11 for acquired causes of dementia
• reversible causes: alcohol (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metals toxicity, hepatic or renal failure, Wilson's disease, B12 deficiency, ↑/↓ glucose, ↑/↓ cortisol, thyroid dysfunction, normal pressure hydrocephalus, depression (pseudodementia), intracranial tumour, subdural hematoma
• must rule out delirium

Delirium is a medical emergency carrying significant risk of morbidity and mortality. It is characterized by acute onset, disorientation, fluctuating level of consciousness, poor attention, and marked psychomotor changes.

Visual hallucinations more commonly indicate organic disease.
**History**

- "geriatric giants"
  - confusion/incontinence/falls/polypharmacy
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects)
  - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS
- alcohol, smoking
- OTCs, herbal remedies, medications (sedative hypnotics, antipsychotics, antidepressants, anticholinergics), compliance, accessibility
- history of vascular disease or head trauma
- collateral history

**Physical Examination**

- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings, cerebrovascular disease
- general physical exam depending on risk factors and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

**Investigations**

- depends on suspected etiologies (see Tables 10 and 11)
  - CBC (note MCV for evidence of alcohol use and B12 deficiency), glucose, TSH, B12, RBC folate
  - electrolytes, LFTs, renal function, lipids, serum calcium
  - CT head, MRI as indicated, SPECT – optional
  - as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
  - failure to cope, fitness to drive, caregiver education and stress, power of attorney, legal will, advanced medical directives

Alzheimer’s Disease (AD)

• see Psychiatry, PS20

Definition
• progressive cognitive decline interfering with social and occupational functioning characterized by the following
  1. anterograde amnesia: impaired ability to learn new information
  2. one of the following cognitive disturbances
     a. aphasia: language disturbance
     b. apraxia: impaired ability to carry out motor activities despite intact motor function
     c. agnosia: failure to recognize or identify objects despite intact sensory function
     d. disturbance in executive function: impaired planning, organizing, sequencing, abstracting

Pathophysiology
• genetic factors
  - minority (<7%) of AD cases are familial (autosomal dominant)
  - 3 major genes for autosomal dominant AD have been identified:
    - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
  - the E4 polymorphism of apolipoprotein E is a susceptibility genotype (E2 is protective)
• pathology (although not necessarily specific for AD)
  - gross pathology
    - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
  - microscopic pathology
    - senile plaques (extracellular deposits of amyloid in the grey matter of the brain)
    - loss of synapses
    - neurofibrillary tangles (intracytoplasmic paired helical filaments with β-amyloid and hyperphosphorylated Tau protein)
    - loss of cholinergic neurons in nucleus basalis of Meynert that project to the frontal cortex
  - biochemical pathology
    - 50-90% reduction in action of choline acetyltransferase

Epidemiology
• 1/12 of population 65-75 yr of age
• 1/3 of population >85 yr of age
• accounts for 60-80% of all dementias

Risk Factors
• age, family history, smoking, head injury, low education level, Down’s syndrome

Signs and Symptoms
• cognitive impairment
  - memory impairment for newly acquired information (early)
  - deficits in language, abstract reasoning and executive function
• psychiatric manifestations
  - major depressive disorder (5-8%)
  - psychosis (20%)
  - apathy
• motor manifestations (late)
  - parkinsonism (if present consider DLB)

Investigations
• perform investigations to rule out other causes of dementia as necessary
• EEG: usually normal, may observe generalized slowing (nonspecific)
• MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
• SPECT: hypoperfusion in temporal and parietal lobes

Cholinesterase Inhibitors for Dementia with Lewy bodies (DLB), Parkinson’s Disease Dementia (PDD) and Cognitive Impairment in Parkinson’s Disease (CIND-PD)
Cochrane DB Syst Rev 2012;3:CD006504
Study: Meta-analysis of RCTs assessing efficacy of treatment with cholinesterase inhibitors in DLB, PDD, and CIND-PD.
Results: The six trials (n=1238) included demonstrated therapeutic benefit of cholinesterase inhibitor for global assessment, cognitive function, behavioural disturbance, and activities of daily living. Cholinesterase Inhibitor was associated with increased adverse events (OR 1.64) and drop out (OR 1.94). Adverse events were more common with rivastigmine but not with donepezil. Fewer deaths occurred in the treatment group (OR 0.28).
Conclusion: Current evidence supports use of cholinesterase Inhibitors for patients with PDD but its role in DLB and CIND-PD is still unclear.

4 As and one D of AD
Anterograde amnesia
Aphasia
Apraxia
Agnosia
Disability in executive function
(Anterograde amnesia plus at least one of the other features is required for AD diagnosis)

Down’s syndrome predisposes to early onset of Alzheimer’s (i.e. age of ~40) due to three copies of the amyloid gene (APP)
**Treatment**

- acetylcholinesterase inhibitors have been shown to slow decline in cognitive function
  - donepezil, rivastigmine, galantamine
  - relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers or risk factors for ulcers and GI bleeding
- galantamine is contraindicated in patients with hepatic/renal impairment
- memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
- symptomatic management
  1. pharmacologic
     - low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
     - trazodone for sleep disturbance
     - antidepressants (SSRIs)
  2. non-pharmacologic
     - redirection
     - explore inciting factors for behaviour and modify behavior of patient or caregiver
     - family support and day care facilities

**Prognosis**

- progressive with mean duration of disease 10 yr

---

### Dementia with Lewy Bodies (DLB)

**Definition**

- progressive cognitive decline interfering with social or occupational function; memory loss usually not an early feature
- one (possible DLB) or two (probable DLB) of the following:
  - fluctuating cognition with pronounced variation in attention and alertness
  - recurrent visual hallucinations
  - parkinsonism (not to be confused with Parkinson’s disease dementia)
  - suggestive or supportive features include REM sleep disorder, sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms), repeated falls (late disease)

**Etiology and Pathogenesis**

- Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
- mixed DLB and AD pathology is common

**Epidemiology**

- 15-25% of all dementias

**Treatment**

- acetylcholinesterase inhibitors (e.g. donepezil)

**Prognosis**

- typical survival 3-6 yr

---

### Frontotemporal Dementia (FTD)

**Definition**

- FTD is a progressive dementia; third most common cause of cortical dementia
- behavioural variant of FTD (more common) presents with social conduct disorder predominantly
- language variants:
  1. progressive nonfluent aphasia: non-fluent, laboured articulation/speech, anoma, preserved single word comprehension, word-finding deficit, impaired repetition
  2. semantic dementia: fluent, normal rate, anoma, impaired single word comprehension, intact repetition, use words of generalization (“thing”) or superordinate categories (“animal” for “dog”)

**Etiology and Pathogenesis**

- unknown, likely genetic/familial component
- two main histological types:
  1. frontal lobe degeneration with microvacuolar change
  2. Pick type with astrocytic gliosis ± ballooned cells and inclusion bodies

**Epidemiology**

- 10% of all dementias
Signs and Symptoms
- diagnosis of behavioural variant of FTD:
  - core features:
    1. insidious onset and gradual progression
    2. early decline in social interpersonal conduct
    3. early impairment in regulation of personal conduct
    4. early emotional blunting
    5. early loss of insight
  - supportive features:
    1. behavioural (decline in personal hygiene, mental rigidity, distractibility, hyperorality, perseverative or utilization behaviour)
    2. speech and language (perseverative or stereotyped speech, echolalia, mutism)
    3. physical signs (primitive reflexes, incontinence, akinesia, rigidity, tremor, low and labile blood pressure)
- severe frontal lobe impairment in absence of severe amnesia, aphasia, perceptual disorder
- imaging: predominant frontal and/or anterior temporal atrophy
- EEG usually normal

Creutzfeldt-Jakob Disease (CJD)
- rare degenerative fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)
- investigations: CSF analysis, MRI brain (cortical and/or subcortical FLAIR changes), EEG (periodic complexes)
- definitive diagnosis is by brain biopsy
- no treatments currently exist

Normal Pressure Hydrocephalus
- see Neurosurgery, NS8

Aphasia
Definition
- an acquired disturbance of language characterized by errors in speech production, writing, comprehension, or reading

Neuroanatomy of Aphasia
- Broca’s area (posterior inferior frontal lobe) involved in speech production (expressive)
- Wernicke’s area (posterior superior temporal lobe) involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke’s area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke’s and Broca’s areas

Assessment of Language
- assessment of context
  - handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
  - spontaneous speech (fluency, paraphasias, repetition, naming, comprehension – auditory and reading, writing, neologisms)

*Transcortical aphasias are typically associated with cerebral anoxia (e.g. post-MI, CO poisoning, hypotension)
Apraxia

Definition
• inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension or inattention

Clinicopathological Correlations

Table 13. Apraxia

<table>
<thead>
<tr>

Mild Traumatic Brain Injury

Definition
• mild TBI = concussion
• trauma induced transient alteration in mental status that may involve loss of consciousness
• hallmarks of concussion: confusion and amnesia, which may occur within minutes
• loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15 and post-traumatic amnesia must be less than 24 h

Epidemiology
• 75% of TBIs are estimated to be mild; remainder are moderate or severe (see Neurosurgery, NS30 and Emergency Medicine, ER7)
• highest rates in children 0-4 yr, adolescents 15-19 yr and elderly >65 yr

Clinical Features
• impairments following mild TBI:
  ▪ somatic: headache, sleep disturbance, nausea, vomiting, blurred vision
  ▪ cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  ▪ emotion and behaviour: impulsivity, irritability, depression
• severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
• associated conditions: brain contusion, diffuse axonal injury, C-spine injury
Investigations
• neuro exam to identify focal neurologic deficits
• neurocognitive assessment:
  ▪ simple orientation questions are inadequate to detect cognitive changes
  ▪ initial assessment of severity is determined by:
    • Glasgow Coma Scale: mild: 13-15, moderate: 9-12, severe: 3-8
    • sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
• neuroimaging:
  ▪ x-ray of skull: not indicated for routine evaluation of MTBI
  ▪ CT head as indicated by Canadian CT Head Rules (see Emergency Medicine, ER10)
  ▪ MRI not indicated in initial evaluation – indicated in presence of continued or worsening symptoms despite normal CT

Treatment
• observation for first 24 h after mild TBI in all patients because of risk of intracranial complications
• emergency department for assessment if any loss of consciousness or persistent symptoms
• hospitalization if: with normal CT (GCS <15, seizures, bleeding diathesis), abnormal CT scan
• early rehabilitation to maximize outcomes
  ▪ OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
• pharmacological management of headaches, pain, depression
• cognitive behavioural therapy, relaxation therapy
• follow Return to Play guidelines (www.thinkfirst.ca)

Prognosis
• most recover from mild TBI with minimal treatment, but some experience long-term consequences
• athletes with a previous concussion are at increased risk of subsequent concussion and cumulative brain injury
• repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
• sequelae include
  ▪ postconcussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
  ▪ post-traumatic headaches: begin within seven days of injury
  ▪ post-traumatic epilepsy: twofold increase in risk of epilepsy in 5 yr post TBI, prophylactic anticonvulsants not effective
  ▪ post-traumatic vertigo

<tr>
<td>Bradykinesia</td>
<td>Slow and/or small amplitude movements</td>
</tr>
<tr>
<td>Chorea</td>
<td>Brief, abrupt, irregular movements; can appear purposeful in milder forms</td>
</tr>
<tr>
<td>Dyskinesia</td>
<td>Any sudden involuntary movement, but the term is often used to describe the stereotypical movements that come with long term neuroleptic or dopaminergic use</td>
</tr>
<tr>
<td>Dystonia</td>
<td>Co-contraction of agonist and antagonists causing sustained twisting movements</td>
</tr>
<tr>
<td>Freezing</td>
<td>Episodes of halted motor action, especially during walking</td>
</tr>
<tr>
<td>Hemiballismus</td>
<td>Unilateral violent flinging movement</td>
</tr>
<tr>
<td>Myokimia</td>
<td>Brief muscle group contraction that is either focal, segmental, or generalized</td>
</tr>
<tr>
<td>Myoclonus</td>
<td>Spontaneous, fine, fascicular contraction of muscle</td>
</tr>
<tr>
<td>Tics</td>
<td>Stereotyped repetitive actions due to inner urge; can be suppressed</td>
</tr>
<tr>
<td>Tremor</td>
<td>Rhythmic alternating muscle contraction and relaxation</td>
</tr>
</tbody>
</table>

Function of the Basal Ganglia

- The cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, which then activate two pathways: direct and indirect
  - Direct: cortex → striatum → GPi/SNr → thalamus → motor cortex
    - Activation of this pathway removes the inhibitory effect of the GPi on the thalamus, letting the thalamus activate the cortex and ultimately allowing movement
  - Indirect: cortex → striatum → GPe → STN → GPi/SNr → thalamus → motor cortex
    - Activation of this pathway causes inhibition of the thalamus and ultimately prevents movement

Figure 20. Neural connections of the basal ganglia

In some cases, dystonias may only occur during voluntary movement and sometimes only during specific activities such as writing, chewing, or speaking.

Hemiballismus is a prominent unilateral chorea that is most often due to a vascular lesion of the contralateral subthalamic nucleus.

Some myoclonus is stimulus sensitive and can be induced by noise, movement, light, visual threat or pinprick.
**Movement Disorders**

**Differential Diagnoses**

1. **Tremor:**
   - **postural:** physiologic, anxiety, sedative/alcohol withdrawal, drug toxicity, heavy metal poisoning, carbon monoxide poisoning, thyrotoxicosis, benign essential tremor, cerebellar, Wilson's disease
   - **benign essential tremor** is a common autosomal dominant trait that presents as a bilateral postural tremor of the vertical axis, especially in the upper extremities
   - **intention:** brainstem lesion, cerebellar lesion, alcohol, anticonvulsants, sedatives, Wilson's disease
   - **resting:** Parkinsonism, Wilson's disease, mercury poisoning

   ![Image of basal ganglia](https://via.placeholder.com/150)

2. **Chorea:** Huntington\'s disease, neuroacanthocytosis, SLE, APLA syndrome, Wilson\'s disease, cerebrovascular disease, tardive dyskinesia, senile chorea, Sydenham\'s chorea, pregnancy chorea

3. **Dystonia**
   - **primary dystonia:** familial, sporadic (torticollis, blepharospasm, writer\'s cramp)
   - **dystonia-plus syndromes:** dopa-responsive dystonia, myoclonus-dystonia
   - **secondary dystonia:** thalamotomy, stroke, CNS tumour, demyelination, PNS injury, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
   - **heterodegenerative dystonias:** Parkinsonian disorders, Wilson\'s disease, Huntington\'s disease

4. **Myoclonus**
   - **physiologic myoclonus:** hiccups, nocturnal myoclonus
   - **essential myoclonus**
   - **epileptic myoclonus**
   - **symptomatic myoclonus:**
     - degenerative disorders (Wilson\'s disease, Huntington disease, Alzheimers)
     - infectious disorders (CJD, viral encephalitis, AIDS-dementia complex)
     - metabolic disorders (drug intoxication/withdrawal, hypoglycemia, hyponatremia, HONK, hepatic encephalopathy, uremia, hypoxia)
     - focal brain damage (head injury, stroke, mass)

   ![Palatal myoclonus](https://via.placeholder.com/150)

   Palatal myoclonus can result from lesion to the dentatorubroolivary pathway, and is associated with an audible clicking.

   ![In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson\'s disease), and CT/MRI (cerebellar disease) as indicated by type of tremor.](https://via.placeholder.com/150)

   In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson\'s disease), and CT/MRI (cerebellar disease) as indicated by type of tremor.

   ![Alcohol](https://via.placeholder.com/150)

   Alcohol
   - Dampens essential tremor
   - Potentiates intention tremor
   - Does not improve resting tremor of PD

   ![> 90% of essential tremor does not need treatment.](https://via.placeholder.com/150)

   > 90% of essential tremor does not need treatment.

   ![Most common cause of chorea is drug therapy for PD.](https://via.placeholder.com/150)

   Most common cause of chorea is drug therapy for PD.
5. Tics
- **primary tic disorders**: transient tic disorder, chronic tic disorder, Gilles de la Tourette, adult onset or senile
- **secondary tic disorders**: encephalitis, CJD, Sydenham's chorea, head trauma, drugs, mental retardation syndromes
- association with OCD and ADHD

## Parkinson's Disease (PD)

### Etiology
- **sporadic**: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g., pesticides), accelerated aging, genetics
- **familial** (10%): autosomal dominant α-synuclein mutations, autosomal recessive Parkin gene or DJ-1 gene mutation (juvenile onset)
- **MPTP** (neurotoxin)

### Epidemiology
- mean age of onset is 60 yr
- family history, male, head injury, rural living, exposure to certain neuro toxins

### Pathophysiology
- loss of dopaminergic neurons in pars compacta of substantia nigra, thus reduced dopamine in striatum leading to disinhibition of the indirect pathway and decreased activation of the direct pathway causing increased inhibition of cortical motor areas
- α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neuritoxicity in substantia nigra

### Signs and Symptoms
- **positive motor**
  - resting tremor: asymmetric 4-5Hz "pill-rolling" tremor, especially in hands
  - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
- **negative motor**
  - bradykinesia: slow small amplitude movements, fatiguing of rapid alternating movements, difficulty initiating movement
- related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
- postural instability: late finding presenting as falls, festinating gait
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary retention, sexual dysfunction, later findings of orthostatic hypotension

### Treatment
- pharmacologic
  - mainstay of treatment: Sinemet® (levodopa/carbidopa). Levodopa is a dopamine precursor; carbidopa decreases peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
  - levodopa related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration ("wearing-off"), random oscillations of on-off symptoms
  - major complication of levodopa is dyskinesia
  - treatment of early PD: dopamine agonists, amantadine, MAOI
  - adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), COMT inhibitors
- surgical: thalamotomy, pallidotomy, DBS (thalamic, pallidal, subthalamic), embryonic dopaminergic stem cell transplantation
- psychiatric (see Psychiatry, PS21)

### Consider an Alternative Diagnosis if Atypical Parkinsonism
- **poor response to L-dopa**
- **abrupt onset of symptoms**
- **rapid progression**
- **early falls**
- **early autonomic dysfunction**
- **symmetric symptoms at onset**
- **early age of onset (<50)**
- **early cognitive impairment**
- **Fx of psychiatric/dementing disorders**
- **recent diagnosis of psychiatric disease**
- **history of encephalitis**
- **unusual toxin exposure**
- **extensive travel history**

### Dopamine Agonist Therapy in Early Parkinson's Disease
- **Cochrane DB Syst Rev 2009;2:CD006564**
- **Study**: Meta-analysis of trials of dopamine agonists in early Parkinson's disease.
- **Results**: Twenty-nine trials were included (n=5247). Dopamine agonists were found to have decreased motor side effects (dyskinesia OR 0.51, dystonia OR 0.64, motor fluctuations OR 0.51) compared to levodopa, but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation OR 1.69, hallucinations OR 1.90, dizziness OR 1.45).
- **Conclusion**: Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.
Other Parkinsonian Disorders

- dementia with Lewy bodies (see Behavioural Neurology, N20)
- progressive supranuclear palsy: tauopathy with limited vertical gaze (classically downgaze), early falls, axial rigidity and akinesia, dysarthria and dysphagia
- corticobasal degeneration: tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia ± “alien limbs” phenomenon
- multiple system atrophy: synucleinopathy presenting as either cerebellar predominant (previously olivo-ponto cerebellar atrophy or OPCA) or parkinsonism predominant (previously striato-nigral degeneration). Both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- vascular parkinsonism: multi-infarct presentation with lower body parkinsonism

Huntington’s Disease

Etiology and Pathogenesis
- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway and decreased activity of the indirect pathway

Epidemiology
- North American prevalence 4-8/100,000
- mean age of onset 35-44 yr; but varies with degree of anticipation from 5-70

Signs and Symptoms
- typical progression: insidious onset with clumsiness, fidgetiness and irritability, progressing over 15 yr to frank dementia, psychosis and chorea
  - dementia: progressive memory impairment and loss of intellectual capacity
  - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudopurposeful movement to mask involuntary limb jerking)
  - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
  - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence

Investigations
- MRI: enlarged ventricles, atrophy of cerebral cortex and caudate nucleus
- genetic testing
  - expansion of the cytosine-adenine-guanine (CAG) trinucleotide repeats in the HTT gene
  - CAG repeats on chromosome 4p16.3 that encodes the protein huntingtin

Treatment
- no disease altering treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: neuroleptics and benzodiazepines
- dystonia: botulinum toxin

Dystonia

Epidemiology
- second most common movement disorder, after parkinsonism

Clinical Features
- symptoms exacerbated by fatigue, stress, emotions; relieved by sleep or specific tactile/proprioceptive stimuli (‘geste antagoniste’, e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalize if younger onset or leg dystonia

Treatment
- local medical: botulinum toxin
- systemic medical: anticholinergics (benztropine), muscle relaxants (baclofen), benzodiazepines, antiparkinsonergics (reserpine, neuroleptics); dopamine for dopa-responsive dystonia
- surgical: surgical denervation of affected muscle, stereotaxic thalamotomy (unilateral dystonia), posteroverentral pallidotomy
Tic Disorders

Clinical Classification
- **motor tics**
  - *simple*: blinking, head jerking
  - *dystonic*: bruxism, grinding teeth, abdominal tension, sustained mouth opening
  - *complex*: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- **vocal tics**
  - *simple*: blowing, coughing, grunting, throat clearing
  - *complex*: coprolalia (shout obscenities), echolalia (repeat others’ phrases), palilalia (repeat own phrases)

Treatment
- dopamine blocker

Tourette’s Syndrome (aka Gilles de la Tourette’s Syndrome)

Definition according to DSM IV
1. Presence of motor and vocal tics at some point during illness, not necessarily concurrently
2. Multiple tics a day nearly everyday or intermittently throughout 1 yr with no tic-free periods greater than 3 mo
3. Onset prior to 18 yr of age
4. Not due to effect of a substance or general medical condition

Epidemiology
- prevalence among adolescents 3-5/100,000; M>F

Signs and Symptoms
- **tics**: wide variety that wax and wane in type and severity
  - can be voluntarily suppressed for some time but are preceded by unpleasant sensation that is relieved once tic is carried out
- psychiatric: compulsive behaviours (associated with OCD and ADHD), hyperactive behaviour, rages, sleep-wake disturbances, learning disabilities

Treatment
- clonidine, clonazepam

Prognosis
- begins at 5 yr of age progressively increasing until 10 yr; often improves in adolescence and 50% are tic-free by 18 yr of age

Cerebellar Disorders

Clinico-Anatomic Correlations
- **vermis**: trunk/gait ataxia
- **cerebellar lobe (i.e. lateral)**: rebound phenomenon, scanning dysarthria, dysdiadochokinesia, dysmetria, nystagmus

Symptoms and Signs of Cerebellar Dysfunction
- nystagmus: observe on extra-ocular movement testing (most common is gaze-evoked nystagmus)
- dysarthria (ataxic): abnormal modulation of speech velocity and volume – elicit scanning/telegraphic/slurred speech on spontaneous speech (see CN X Vagus Nerve, N10)
- ataxia: broad-based, uncoordinated, lurching gait
- dysmetria: irregular placement of voluntary limb or ocular movement
- dysdiadochokinesia: impairment of rapid alternating movements (e.g. pronation – supination task)
- postural instability: truncal ataxia on sitting, titubation (rhythmic rocking of trunk and head), difficulty with tandem and broad-based gait
- intention tremor: typically orthogonal to intended movement, and increases as target is approached
- hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
- pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres)
- rebound phenomenon: overcorrection after displacement of a limb
- ocular apraxia: gaze dysmetria

**Wernicke-Korsakoff Syndrome**

- see Psychiatry, PS23
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

**Cerebellar Ataxias**

**Congenital Ataxias**
- early onset nonprogressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

**Hereditary Ataxias**
- autosomal recessive: includes Friedrich’s ataxia, ataxia telangiectasia, vitamin E deficiency
  - signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
  - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- autosomal dominant: most commonly spinocerebellar ataxias (30 types, most due to CAG repeats)
  - signs: ataxia and dysarthria; ± myoclonus, chorea, polyneuropathy, pyramidal or extrapyramidal features, hyporeflexia, seizures, dementia

**Acquired Ataxias**
- neurodegeneration (e.g. multiple system atrophy)
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson’s, thiamine deficiency
- toxins: carbon monoxide, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)

**Vertigo**

- see Otolaryngology, OT12

**Gait Disturbances**

**Approach to Gait Disturbances**

1. **Characterization of the gait disturbance**
   - posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, elaborate/inconsistent movements, standing from sitting

2. **Identification of accompanying neurologic signs**
   - full neurological exam required (diagnosis often can be made by P/E alone)

3. **Identify red flags**
   - sudden onset, cerebellar ataxia, paresis (hemi, para or quadra), bowel/bladder incontinence

4. **Work up**
   - based on etiology – requires blood work, neuroimaging and urgent neurologist referral

**Table 17. Types of Gait Disturbance**

**Motor Neuron Disease**

### Amyotrophic Lateral Sclerosis (ALS) (aka Lou Gehrig’s Disease)

**Definition**
- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

**Etiology**
- idiopathic (most), genetic (5-10% familial, especially SOD1 mutation, other: C9orf72, TARDBP)

**Pathology**
- disorder of anterior horn cells of spinal cord, cranial nerve nuclei, and corticospinal tract

**Epidemiology**
- 5/100,000; incidence increases with age

**Signs and Symptoms**
- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, frontotemporal dementia (up to 10%)
- sparing of sensation, ocular muscles and, sphincters

**Investigations**
- EMG: chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (i.e. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out cord disease/compression

**Management**
- riluzole (modestly slows disease progression)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine, regular exercise and physical therapy
  - sialorrhea: TCA (i.e. amitriptyline), sublingual atropine drops, parotid/submandibular botox (rare)
  - pseudobulbar affect: dextromethorphan/quinidine, TCA, SSRI
  - non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (i.e. PEG tube), rehabilitation (PT, OT, SLP), psychosocial support

**Prognosis**
- median survival 3 yr; death due to respiratory failure

### Other Motor Neuron Diseases

- degenerative
  - progressive muscular atrophy (progressive bulbar palsy): only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centres
  - primary lateral sclerosis (progressive pseudobulbar palsy): UMN symptoms, later onset, not fatal with variable disability; 5-10% of patients in ALS centres
  - spinal muscular atrophy: pediatric disease with symmetric LMN symptoms
- infectious
  - post-polio syndrome: residual asymmetric muscle weakness, atrophy
- acquired
  - multifocal motor neuropathy: conduction block on NCS, asymmetric LMN symptoms, ± anti-GM1 Ab, treatable with IVlg

## Peripheral Neuropathies

### Diagnostic Approach to Peripheral Neuropathies

1. Differentiate: motor vs. sensory vs. autonomic vs. mixed
2. Pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. Temporal pattern: acute vs. chronic; relapsing remitting vs. constant vs. progressive
4. History: PMH, detailed FHx, exposures (e.g. insects, toxins, sex, travel), systemic symptoms
5. Detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

### Classification

- **mononeuropathy**: dermatomal deficit due to single nerve root lesion
  - due to disc herniation or root compression causing radicular pain
  - little tactile anaesthesia, as dermatomes overlap
- **polyneuropathy**: single nerve deficit
  - one type is cauda equina syndrome (lumbosacral roots)
- **plexopathy**: deficit matching distribution of a nerve plexus
  - **brachial plexopathy**
    - upper (C5–C7): LMN sx of shoulder and upper arm muscles (Erb’s palsy)
    - lower (C8-T1): LMN sx and sensory sx of forearm and hand (Klumpke's palsy)
  - **lumbosacral plexopathy** (rare, especially unilateral)
  - **Dx**: idiopathic neuritis, infarction (i.e. diabetes), compression
- **mononeuropathy**: single nerve deficit
  - **carpal tunnel syndrome** (most common): compression of median nerve at wrist
    - symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
    - signs: Tinel’s sign, Phalen’s test, thenar muscle wasting, sensory deficit
  - **EMG and NCS**: slowing at wrist (both motor and sensory)
  - **Bell’s palsy** (most common cranial neuropathy): see Otolaryngology, OT22
    - *other less common* mononeuropathies due to entrapment/compression: ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (femoral canal), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)
- **mononeuropathy multiple**: deficit affecting multiple discrete nerves (asymmetric)
  - *must rule out vasculitis or collagen vascular disease*
- **polyneuropathy**: symmetrical distal stocking-glove pattern
  - symmetrical distal sensorimotor deficit affecting longest fibres first (stocking-glove distribution), hypotonia; progression of dysesthesia early and weakness later
  - *etiologies*: DM (most common), renal disease, substances, toxins, genetics, SLE, HIV, leprosy, alcohol, B12 deficiency, uremia
- **chronic inflammatory demyelinating polyneuropathy (CIDP)**
  - chronic relapsing sensorimotor polyneuropathy with increase protein in CSF and demyelination (shown on EMG/NCS)
  - *course* is fluctuating, in contrast with the acute onset of GBS
  - *treatment*: first-line is prednisone; alternatives are plasmapheresis, IVIg, and azathioprine

* DDx of Demyelinating Neuropathy
  - GBS, CIDP, paraproteinemia, diphtheria, amiodarone, Charcot-Marie-Tooth, storage diseases, pressure palsies, predisposition, paraneoplastic.
  - Axonal neuropathies have decreased amplitude on NCS; demyelinating neuropathies have decreased velocity on NCS.
  - Otoxic drugs (e.g. aminoglycosides) should not be given to diabetics.
  - Sensory neuropathy of the feet prevent them from adequately compensating for loss of vestibular function.

- **Tinel’s Sign**: tap lightly over the median nerve at the wrist. The patient’s symptoms of carpal tunnel will be elicited in a positive test.
- **Phalen’s Test**: hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s. Test is positive if symptoms of carpal tunnel are elicited.

- **Toronto Notes 2014**
- **Role of Laboratory and Genetic Testing**
  - **Evaluation of Distal Symmetric Polyneuropathy**
    - **Rule of Laboratory and Genetic Testing**
      - **Neurology** 2009/12:185-192
      - Screening lab tests: Blood glucose, serum B12 with metabolites, serum protein immunofixation electrophoresis.
      - Genetic testing: Indicated for cryotogenic polyneuropathy exhibiting classic hereditary neuropathy phenotype. Screen for CMT1A duplication/deletion and Cx32 mutations.

*Abbreviations: CIDP – chronic inflammatory demyelinating polyradiculoneuropathy; GGT – gamma-glutamyl transferase; HMSN – hereditary motor sensory neuropathy; OGTT – oral glucose tolerance test; PAN – polyarteritis nodosa; RA – rheumatoid arthritis; SLE – systemic lupus erythromatosus; SPEP – serum protein electrophoresis; S – sensory; M – motor; A – autonomic

Guillain-Barré Syndrome (GBS)

- **Definition:** acute rapidly evolving polyneuropathy that often starts in the distal lower limbs and ascends
- **Etiology**
  - autoimmune attack and damage to peripheral nerve myelin
  - sometimes preceded by viral/bacterial infections
- **Signs and Symptoms**
  - sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
  - motor: weakness starting distally in legs, areflexia
  - autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction
- **Investigations**
  - CSF: albuminocytological dissociation (high protein, normal WBC)
  - EMG/NCS: conduction block, differential or focal (motor>sensory) slowing, decreased F-wave, sural sparing
- **Subtypes**
  1. acute inflammatory demyelinating polyneuropathy (AIDP)
  2. acute motor-sensory axonal neuropathy (AMSAN)
  3. acute motor axonal neuropathy (AMAN)
- **Treatment**
  - IVIg or plasmapheresis, ± pain management, monitor vitals and vital capacity
- **Prognosis**
  - peak of symptoms at 2-3 wk, resolution at 4-6 wk
  - 5% mortality (higher if require ICU); up to 15% have permanent deficits

Myasthenia Gravis (MG)

**Etiology and Pathophysiology**

- progressive autoimmune disorder due to anti-AChR antibodies, resulting in early saturation at the NMJ and inadequate muscle activation with increasing nerve stimulation
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia
Epidemiology
• bimodal age of onset – 20s (mostly women) and 60s (mostly men)

Signs and Symptoms
• see Table 19
• fatiguable, symmetric or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
• ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
• symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
• respiratory muscle weakness may lead to respiratory failure

Investigations
• edrophonium (Tensilon*) test
  ▪ assess for improvement over 2 min following edrophonium injection
• EMG
  ▪ repetitive stimulation → decremental response
  ▪ single fibre electromyography shows increased jitter (80-100% sensitivity)
  ▪ spirometry – forced vital capacity may be used to monitor adequacy of respiratory effort over time
• anti-acetylcholine receptor antibody assay (70-80% sensitivity)
• MUSK antibody may be used if seronegative for AChR antibody
• CT/MRI to screen for thymoma/thymic hyperplasia

Treatment
• thymectomy
  ▪ 85% of patients show improvement or remission
• symptomatic relief
  ▪ acetylcholinesterase inhibitors (e.g. pyridostigmine)
  ▪ does not affect primary pathologic process so rarely results in control of disease when used alone
• immunosuppression
  ▪ steroids are mainstay of treatment (70-80% remission rate)
  ▪ azathioprine, cyclophosphamide and mycophenolate as adjuncts or as steroid sparing therapy
  ▪ short-term immunomodulation (for crises)
  ▪ IVlg and plasmapheresis

Prognosis
• 30% eventual spontaneous remission
• with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

Lambert-Eaton Myasthenic Syndrome (LEMS)

Etiology and Pathophysiology
• autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
• 50-66% are associated with small cell carcinoma of the lung

Signs and Symptoms
• see Table 19
• weakness of skeletal muscles without sensory or coordination abnormalities
• reflexes are diminished or absent, but increase after active muscle contraction
• bulbar and oculomotor muscles affected in 25% (vs. 90% in MG)
• prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

Investigations
• edrophonium test (see Myasthenia Gravis, N32) → no response
• EMG
  ▪ rapid (>10 Hz) repetitive stimulation → incremental response
  ▪ post-exercise facilitation → an incremental response with exercise
  ▪ screen for malignancy, especially small cell lung cancer

Treatment
• tumour removal
• acetylcholine modulation
  ▪ increased acetylcholine release (3,4-diaminopyridine)
  ▪ decreased acetylcholine degradation (pyridostigmine)
• immunomodulation
  ▪ steroids, plasmapheresis, IVlg

Figure 22. Myasthenia gravis
Tensilon® is a drug that inhibits acetylcholinesterase. It improves muscle function immediately in myasthenia gravis, but not in a cholinergic crisis. This test is infrequently used. When performed, a crash cart should be nearby as respiratory difficulty and/or bradycardia may occur.

Figure 23. Lambert-Eaton myasthenic syndrome (LEMS)
Botulism

Etiology and Pathophysiology
- caused by a toxin produced by spores of *Clostridium botulinum* bacteria, which is found in soil and water throughout the world. Bacteria can enter the body through wounds or by ingesting improperly preserved foods
- infantile botulism is the most common form, and is usually from ingestion of honey or corn syrup

Signs and Symptoms
- occur 6–48 h after ingestion
- difficulty with convergence, ptosis, paralysis of extraocular muscles
- dilated, poorly reactive pupils
- other autonomic dysfunction: jaw weakness, dysarthria, dysphagia
- spreads to trunk and limbs
  - abdominal cramps with nausea and vomiting
  - symmetric weakness with paralysis and absent/decreased deep tendon reflexes
  - anticholinergic symptoms: dry mouth, constipation, urinary retention
- rarely respiratory distress, potentially advancing to respiratory failure

Investigations
- blood test for toxin
- stool culture

Treatment
- botulinum anti-toxin – good prognosis with prompt treatment
- supportive therapy as required

Myopathies

</tbody>
</table>

Myopathies are characterized by prominent symmetric proximal weakness and absent sensory changes.

Good Questions to Assess Proximal Weakness
- Legs: climbing stairs, stand from sit
- Arms: reach above head, wash hair

Common Medications that Cause Myopathy: steroids, statins, antiretrovirals, thyroxine, fibrates, cyclosporine, ipecac.

Common Drugs that Cause Myopathy: ethanol, cocaine, heroin.

</table>

MERRF = mitochondrial encephalomyopathy with ragged red fibers; MELAS = mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes

**Polymyositis/Dermatomyositis**

- see Rheumatology, RH15

**Myotonic Dystrophy**

Etiology and Pathophysiology
- unstable trinucleotide (CTG) repeat in DMK gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms
- autosomal dominant

Epidemiology
- most common adult muscular dystrophy
- prevalence 3-5/100,000

Signs and Symptoms
- appearance: ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance
- physical exam
  - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
  - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
  - cardiac: 90% have conduction defects (1st heart block; atrial arrhythmias)
  - respiratory: hypoventilation 2nd to muscle weakness
  - ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
  - other: diabetes, infertility, testicular atrophy
- EMG: subclinical myotonia – long runs with declining frequency and amplitude

Treatment and Prognosis
- no cure, progressive, death usually around 50 yr
- management of myotonia: phenytoin

**Duchenne and Becker Muscular Dystrophy**

- see Pediatrics, P44

**Pain Syndromes**

**Approach to Pain Syndromes**

Definitions
- nociceptive pain: pain arising from normal activation of peripheral nociceptors
- neuropathic pain: pain arising from direct injury to neural tissue, bypassing nociceptive pathways
- spontaneous pain: unprovoked burning, shooting, or lancinating pain
- paresthesiae: spontaneous abnormal nonpainful sensations (e.g. tingling)
- dyesthesiae: evoked pain with inappropriate quality or excessive quantity
- allodynia: a dyesthetic response to a non-noxious stimulus
- hyperalgesia: an exaggerated pain response to a noxious stimulus

- Pinprick sensation mediated by Aδ fibers
- Pain due to tissue damage is mediated by C fibers
Non-pharmacological Management
- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (CBT, family therapy, education, psychotherapy)

Medical Pain Control
- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxybenzamine), α2-adrenergic agonists (clonidine)

Surgical Pain Control
- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy or dorsal root entry lesion
- DBS or dorsal column stimulation

**Neuropathic Pain**

Definition
- pain resulting from a disturbance of the central or peripheral nervous system

Symptoms and Signs
- hyperalgesia/allodynia
- subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness (i.e. stocking/sock distribution)
- can be spontaneous or stimulus evoked
- distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

Causes of Neuropathic Pain
- sympathetic
  - complex regional pain syndrome
- central: abnormal CNS activity
  - phantom limb, post spinal cord injury, post stroke, MS
- non-sympathetic: damage to peripheral nerves
  - systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis
  - nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
  - infectious: post-herpetic, HIV
  - trauma/compression: nerve entrapment, trigeminal neuralgia, post surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy

Treatment
- identify/treat underlying cause
- pharmacotherapy
  - Stepwise approach (Canadian Pain Society, 2007): TCA, anticonvulsant, SNRI, topical lidocaine, long acting opiate (caution), tramadol
  - other: capsaicin cream, intrathecal opioid or clonidine, botulinum toxin injection, nerve block
- common non-pharmacologic therapies
  - neuropsychiatry: cognitive behavioural therapy, psychotherapy
  - rehabilitation: physiotherapy
  - complementary and alternative medicine: acupuncture, meditation, massage therapy, traditional Chinese medicine
- surgical therapies: dorsal column neurostimulator, DBS (thalamus)

**Tic Douloureux (Trigeminal Neuralgia)**

Clinical Features
- recurrent episodes of sudden onset, excruciating unilateral paroxysmal shooting “electric” pain in trigeminal root territory (V3\(\geq\)V2\(\geq\)V1)
- may have normal sensory exam
- pain lasts seconds/minutes over days/weeks; may remit for weeks/months
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up
Etiology
- **classic TN:** idiopathic
- **secondary TN:** compression by tortuous blood vessel (superior cerebellar artery), cerebellopontine angle tumour (5%), multiple sclerosis (5%)

Epidemiology
- **F > M:** usually middle-aged and elderly

Diagnosis
- clinical diagnosis
- investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
  - MRI to rule out structural lesion, MS or vascular lesion

Treatment
- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- narcotics not generally recommended
- if medical treatment fails: Gasserian ganglion percutaneous technique, gamma knife, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression

---

**Postherpetic Neuralgia (PHN)**

Clinical Features
- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
- distribution: thoracic, trigeminal, cervical > lumbar > sacral
- associated impaired sleep, decreased appetite, decreased libido

Etiology and Pathogenesis
- destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

Epidemiology
- incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
- risk factors: older age, greater acute pain, greater rash severity

Prevention
- varicella zoster vaccine in childhood reduces incidence of varicella zoster
- herpes zoster vaccine (Zostavax®) reduces incidences of shingles, PHN and other herpetic sequel (currently recommended in Canada for those >60 yr old)

Treatment
- medical: TCA (i.e. amitryptiline), anti-convulsants (i.e. pregabalin, gabapentin), analgesia (i.e. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  - early treatment of acute herpes zoster with antivirals (acyclovir; longer-acting famciclovir and valacyclovir more effective)
  - treatment of herpes zoster with corticosteroids DOES NOT decrease PHN
- surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

---

**Painful Diabetic Neuropathy**

Approach
- determine if pain is neuropathic or vascular
- more likely neuropathic if:
  - foot > calves
  - sharp/tingling pain
  - pain present at rest and improves with walking

Treatment
- **Level A:** pregabalin
- **Level B:** venlafaxine, duloxetine, amitryptyline, gabapentin, valproate, rarely opioids, capsaicin
Complex Regional Pain Syndromes (CRPS)

Clinical Features
• presence of an initiating noxious event (MI, stroke)
• continuing pain, allodynia, or hyperalgesia with pain disproportionate to inciting event
• evidence during the course of symptoms of edema, changes in skin blood flow or abnormal vasomotor activity
• absence of conditions that would otherwise account for degree of pain and dysfunction
• other features can include edema, osteoporosis, hyperhydrosis, hair loss, fascial thickening

Classification
• CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
• CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

Investigations
• trial of differential neural blockade may be helpful in diagnosis
• autonomic testing (evidence of sympathetic dysfunction)
• bone scan, plain radiography, MRI

Prevention
• early mobilization after injury/infarction

Treatment
• goal of treatment: to facilitate function
• conservative treatment: education, support groups, PT/OT, smoking cessation
• medical: topical capsaicin, TCA, NSAID, tender point injections with corticosteroid/lidocaine, gabapentin/pregabalin/lamotrigine, calcitonin or bisphosphonates, oral corticosteroids
• surgical: paravertebral sympathetic ganglion blockade
• refer to pain management clinic

Headache

Clinical Approach
• history
  ▪ pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/cough/Valsalva)
  ▪ associated symptoms: visual changes, change in mental status, nausea/vomiting, fever, meningismus, photophobia, phonophobia, TMJ popping/clicking, jaw claudication, neurological sx
  ▪ precipitating/accelerating factors (triggering factors, analgesics), medications (esp. nitrates, CCBs, NSAIDs, anticoagulants), PMH, FHx
  ▪ red flags (possible indications for CT scan/further investigation): new-onset headache (esp. if age <5 or >50), quality worse/different than previous headaches, sudden and severe (‘thunderclap’), immunocompromised, fever, focal neurological deficits, trauma
• physical
  ▪ vitals (including BP and temp), Kernig’s/Brudzinski’s, MSK examination of head and neck
  ▪ HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
  ▪ full neurologic exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
  ▪ red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

Classification
• primary
  ▪ tension, migraine, cluster, exertional, cervical OA, TMJ syndrome
• secondary
  ▪ SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN or pseudotumour cerebri), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post lumbar puncture, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

The Rational Clinical Examination: Does this Patient with Headache have a Migraine or Need Neuroimaging?

JAAMA 2006;296:1274-1283

Does this patient with headache have a migraine?

The most useful panel of questions for diagnosing migraine is summarized by the POUNDING mnemonic:

- **P** – Pulsatile quality
- **D** – Duration of 4-72 hrs
- **O** – Unilateral location
- **U** – Unbilaterial
- **N** – Nausea or vomiting
- **A** – Allodynia
- **D** – Disability

The LR for definite or possible migraine diagnosis varies with the number of features present; with ≥4, 3 and ≥2 features, the LRs are 24 (1.5-388), 3.9 (1.3-9.2) and 0.41 (0.32-0.52) respectively.

Anticonvulsants in Migraine Prophylaxis

Cochrane DB Syst Rev 2009;3:CD003228

Study: Meta-analysis of prospective, controlled trials of anticonvulsant drugs in migraine headache prophylaxis.

Results: Twenty-three studies (n=2927) were included. Anticonvulsants reduce migraine frequency by 1.3 attacks per 28 days compared to placebo and double the number of patients for whom migraine frequency is reduced by 50% (RR: 2.25, NNT: 3.9). Valproate and topiramate are better than placebo, while clonazepam, acetazolamide, lamotrigine and vigabatrin are not.

Clinical impact: Decrease in headache frequency by 1.3 attacks per 28 days compared to placebo and double the number of patients for whom migraine frequency is reduced by 50%. Anticonvulsants reduce migraine frequency by 1.3 attacks per 28 days compared to placebo and double the number of patients for whom migraine frequency is reduced by 50% (RR: 2.25, NNT: 3.9). Valproate and topiramate are better than placebo, while clonazepam, acetazolamide, lamotrigine and vigabatrin are not. Several individual clinical features were found to be predictive of significant intracranial pathology:

- **Symptom:** \( \text{OR} = 2.2 \) (2.1-2.3)
- **Cluster-type headache:** \( \text{OR} = 3.5 \) (2.6-4.4)
- **Unilateral headache:** \( \text{OR} = 3.2 \) (2.9-3.5)
- **Cluster headache:** \( \text{OR} = 3.5 \) (2.8-4.0)

Acute and Preventive Pharmacologic Treatment of Cluster Headache

Neurology 2010;75:463-473

Study: Meta-analysis of prospective, double-blind, RCTs of pharmacologic agents for prevention or treatment of CH.

Results: 27 trials were included. Sumatriptan 6 mg SC, zolmitriptan nasal spray 5-10 mg, and 100% oxygen 6-12 L/min received Level A recommendation for acute treatment. For prevention, Level B recommendations were given for intranasal cyclooxygen 100 ug daily and subcutaneous steroid injections.

Conclusion: Sumatriptan, zolmitriptan, and mid flow oxygen are effective acute treatments for CH.

IH – idiopathic intracranial hypertension

Migraine Headaches

Definition (common migraine)
- ≥5 attacks fulfilling each of the following criteria
  - 4-72 h duration
  - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  - 1 of the following: nausea/vomiting, photophobia/phonophobia

Epidemiology
- 18% females, 6% males; frequency decreases with age (especially at menopause)

Etiology and Pathophysiology
- theories of migraine etiology:
  - depolarizing wave of “cortical spreading depression” across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and also activate trigeminal nerve afferent fibres
  - possible association with vasoconstriction/dilation
  - significant genetic contribution
- triggers: stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrates (e.g. processed meats)

Signs and Symptoms
- stages of uncomplicated migraine
  i. prodrome (hours to days before headache onset)
  ii. aura
  iii. headache (see Table 21 for description of typical headache)
  iv. postdrome
- aura
  - fully reversible symptom of focal cerebral dysfunction lasting <60 min
  - examples: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
  - common migraine: no aura
  - classic migraine: with aura (headache follows reversible aura within 60 min)
  - complicated migraine: with severe/persistent sensorimotor deficits
    - examples:
      - basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered level of consciousness)
      - hemiplegic/hemisensory migraine
      - ophthalmoplegic migraine
  - acephalic migraine (i.e. migraine equivalent): aura without headache

Management
- avoid triggers
- mild to moderate migraine
  - 1st line: NSAIDs (ibuprofen, naproxen)
  - moderate to severe migraine
    - triptans (most effective), ergots (dihydroergotamine, DHE)
    - migraine prophylaxis: anticonvulsants (divalproex, topiramate, gabapentin), TCA (amitryptiline, nortriptyline), propranolol, calcium channel blocker (verapamil)
  - prophylactic agent is recommended only if migraine attacks are severe enough to cause impairment of a patient’s quality of life or if a patient has >3 migraines/month that have not responded adequately to treatment.

Pharmacological Treatments for Acute Migraine

Meta-analysis of 54 double-blind, placebo-controlled RCTs of pharmacological treatment of acute migraine of moderate to severe intensity (21,022 patients in total).

Main Results:
- Data were available for 9 oral medications, 2 intranasal medications, and subcutaneous sumatriptan.
- For h/a relief at 2 h, all interventions were effective except Cafergot®, with NNTs ranging from 2.0 for sumatriptan 6 mg SC to 5.4 for naratriptan 2.5 mg. The lowest NNT for oral medication was 2.4 for eletriptan 80 mg.
- For patients pain free at 2 h, the lowest NNT was 2.1 for sumatriptan 6 mg SC, with the lowest NNT for oral medication being 3.1 for naratriptan 10 mg.
- For sustained relief over 24 h, NNT ranged from 2.0 for eletriptan 80 mg to 3.3 for rizatriptan 5 mg. Side effects could not be analyzed systematically. There were no drug-to-drug comparisons.

Conclusion: Overall, most treatments were effective. Subcutaneous sumatriptan and oral triptans were most effective.
Sleep Disorders

Overview of Sleep

Definition
- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many elderly have reduced sleep as a consequence of underlying sleep disorders

Sleep Architecture
- polysomnogram (PSG) measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

Table 24. Sleep Stage Characteristics

Disturbances of Alertness and Sleep

Coma
- see Neurosurgery, NS34

Insomnia
- difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep
- types:
  - sleep state misperception, psychophyslogic insomnia (learned sleep-preventing associations – i.e. clock watching), fatal familial insomnia (rare prion protein mutation causing autonomic dysfunction), idiopathic (lifelong difficulty)
- secondary causes:
  - psychiatric disorders (80% of psychiatric patients): anxiety and depression (see Psychiatry, PS10, PS13)
  - neurologic disorders: neurodegenerative disease, epilepsy, neuromuscular disorders, many others
  - sleep disorders: restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
  - medical conditions: pregnancy, cardiorespiratory (COPD/HF), GERD, pain (arthritis, fibromyalgia, cancer)
  - drugs/toxins: caffeine, alcohol, stimulants, antidepressants, glucocorticoids, sedative withdrawal
- treatment:
  - sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, cognitive behavioral therapy

Drug Effects on Wakefulness and Sleep
- Antihistamines associated with increased sleepiness
- Stimulants increase arousal
- Caffeine (an adenosine antagonist) increase wakefulness
- Benzodiazepines reduce slow wave sleep
- Antidepressants (TCA/MAO-I/SSRI) reduce REM, prolong REM latency
- Alcohol may hasten sleep onset but associated with increased arousals

Avoid sleep medications (esp. in elderly patients) due to increased risk of falls, pseudodepression, memory loss.
Sleep Apnea
- definition
  - disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence
- epidemiology:
  - >2-4% of the population
  - increasing obesity
  - significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)
- types:
  - obstructive sleep apnea: see Respirology, R31
  - central sleep apnea: no effort to breathe over 10 s
  - mixed apnea: starts as central, but eventually becomes obstructive
- etiology of central apnea:
  - heart failure, opiates, brainstem pathology, myotonic dystrophy
- diagnosis: apnea hypopnea index (AHI) or respiratory disturbance index (RDI) should be <5 in the normal or pathologic state
- treatment: conservative measures, dental devices, CPAP (common), surgery (rare), ensure driving safety

Restless Leg Syndrome (RLS) and Periodic Limb Movement Disorder (PLMD)
- definition:
  - urge to move with accompanied uncomfortable sensations that begin or worsen with rest, are partially or totally relieved with movement, and are worse in evening/night
  - RLS refers to sensation
  - PLMD refers to the manifestation
- epidemiology:
  - 10% North Americans, 90% of RLS have PLMD, 50% of PLMD have RLS
- etiology:
  - central (spasticity), or peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use
- treatment:
  - underlying contributors (iron and B₁₂ supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), opioids (only exceptional circumstances)
  - NOT recommended: Sinemet®, causes augmentation

Narcolepsy
- definition/clinical features:
  - excessive daytime sleepiness (all narcolepsy), cataplexy = loss of muscle tone with emotional stimuli (pathognomonic), sleep paralysis (unable to move upon wakening for 2-3 min), hypnagogic hallucinations (vivid dreams or hallucinations at sleep onset)
- epidemiology:
  - prevalence 1:2000, onset in adolescence/early adulthood; life-long disorder
- etiology:
  - presumed autoimmune attack on orexin/hypocretin system, post head injury, multiple sclerosis, hypothalamic tumours; rarely familial
- diagnosis: based on clinical history + multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps
- treatment:
  - sleep hygiene and scheduled brief naps, restricted driving
  - alerting agents modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
  - anti-cataplectic: TCAs, SSRIs, sodium oxybate

Parasomnias
- definition/clinical features: unusual behaviors in sleep with clinical features appropriate to stage of sleep
- etiology: in elderly, REM sleep behavior disorder may be associated with Parkinson’s disease; in children slow wave sleep arousals (sleep walking) may be associated with sleep disordered breathing
- diagnosis: clinical history in children, polysomnography in adults to exclude nocturnal seizures
- treatment: behavioral management (safety, adequate sleep); clonazepam for REM sleep behavior, tonsillectomy if appropriate in children

Circadian Rhythm
- definition/clinical features: abnormalities based on time of day rather than sleep (i.e. jet lag, shift work)
- diagnosis: clinical history

CNS Infections
- see Infectious Diseases, ID19

Spinal Cord Syndromes
- see Neurosurgery, NS28
**Terminology**

- **stroke**: sudden onset of neurological deficits of a vascular basis with infarction of CNS tissue
  - **transient ischemic attack (TIA)**: sudden onset of neurological deficits of a vascular basis without infarction (i.e. resolution)

**Pathophysiology**

- two major types: ischemic (~80%) and hemorrhagic (~20%)
  1. Ischemic
    - **arterial thrombosis**: thrombus formation in artery (local/in situ)
      - **large vessel**: stenosis or occlusion of the internal carotid artery, vertebral, or intracranial arteries
        - mechanisms:
          - insufficient blood flow beyond lesion (hemodynamic stroke)
          - underlying processes: atherosclerosis (most common cause), dissection and vasculitis
      - **small vessel/lacunar**
        - mechanism: chronic hypertension and diabetes cause vessel wall thickening and decreased luminal diameter
        - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule and thalamus)
    - **cardioembolic**: blockage of cerebral arterial blood flow due to particles originating from a cardiac source
      - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
    - **systemic hypoperfusion** (global cerebral ischemia)
      - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia or MI)
      - primarily affects watershed areas (between the major cerebral arterial territories)
  2. Hemorrhagic
    - **intracerebral hemorrhage (ICH)**
      - mechanisms:
        - hypertensive (most common): rupture of small microaneurysms (Charcot-Bouchard aneurysms) causing intraparenchymal hemorrhage
        - most common sites: putamen, thalamus, cerebellum, andpons
        - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, vasculitis, drug use (cocaïne or amphetamines)
    - **subarachnoid hemorrhage (SAH)** see Neurosurgery, NS18

**Stroke Syndromes According to Vascular Territory**

- **ACA**: contralateral leg paresis and sensory loss
- **MCA**: proximal occlusion involves:
  1. contralateral weakness and sensory loss of face and arm
  2. cortical sensory loss
  3. may have contralateral homonymous hemianopia or quadrantanopia
  4. if left hemisphere: aphasia
  5. if right hemisphere: neglect
  6. eye deviation towards the side of the lesion and away from the weak side
- **PCA**:
  1. contralateral hemianopia or quadrantanopia
  2. midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  3. thalamic findings: sensory loss, amnesia, decreased level of consciousness
  4. if bilateral: cortical blindness or prosopagnosia
- **basilar artery** (locked-in syndrome):
  1. quadriparesis
  2. dysarthria
  3. impaired eye movements
- **PICA (lateral medullary or Wallenburg syndrome)**: ipsilateral ataxia, ipsilateral Horner's, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, nausea/vomiting, dysphagia, dysarthria, hiccup
- **medial medullary infarct** (anterior spinal artery, which can be associated with anterior cord infarct): contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
• lacunar infarcts (deep hemispheric white matter):
  • pure motor hemiparesis: posterior limb of internal capsule: contralateral arm, leg, and face
  • pure sensory loss: thalamic: hemisensory loss
  • ataxic hemiparesis: ipsilateral ataxia and leg paresis
  • dysarthria-clumsy hand syndrome: dysarthria, facial weakness, dysphagia, mild hand weakness and clumsiness

Assessment and Treatment of Ischemic Stroke

General Assessment
• ABCs, full vital sign monitoring, check glucose, urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis)
• history
  • onset: time when last known to be awake and symptom free
  • mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
• investigations:
  • non-contrast CT head (STAT): to rule out hemorrhage and assess extent of infarct
  • ECG: to rule out atrial fibrillation (cardioembolic cause)
  • CBC, electrolytes, creatinine, PTT/INR, blood glucose
• imaging (i.e. CT) signs of stroke:
  • loss of cortical white-grey differentiation
  • sulcal effacement (i.e. mass effect decreases visualization of sulci)
  • hypodensity of parenchyma
  • insular ribbon sign
  • hyperdense MCA sign

ACUTE STROKE MANAGEMENT

1. Thrombolysis
• rtPA (recombinant tissue plasminogen activator)
  • given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use:
    • indications: based on NIH Stroke Scale (NIHSS – see sidebar)
    • contraindications: see sidebar

2. Anti-Platelet Therapy
• give at presentation of TIA or stroke if rtPA not received
• antiplatelet agents:
  • ASA: recommended dose 81 mg chewed
  • if patient intolerant to ASA, use other antiplatelet agent (i.e. clopidogrel)

3. Acute Anti-Coagulant Therapy
• for patients with TIA or stroke and atrial fibrillation if rtPA not received
  • recommend IV heparin (or ensuring INR between 2-3 if already anticoagulated on warfarin)

Other Acute Management Issues
• avoid hyperglycemia which can increase the infarct size
• lower temperature if febrile
• prevent complications:
  • NPO if dysphagia (to be reassessed by SLP)
  • DVT prophylaxis if bed-bound
  • initiate rehabilitation early

Blood Pressure Control
• do NOT lower the blood pressure unless the hypertension is severe
  • antihypertensive therapy is withheld for at least 5 d after thromboembolic stroke unless SBP >120 mmHg or DBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection
• acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
• most patients with an acute cerebral infarct are initially hypertensive and their BP will fall spontaneously within 1-2 d
• IV labetalol first-line if needed

Etiological Diagnosis
• further investigations:
  • additional neuroimaging (MRI)
  • vascular imaging: CTA/MRA/carotid dopplers
  • cardiac tests: ECHO, holter monitoring
  • correct etiological diagnosis is critical for appropriate secondary prevention strategies
Primary and Secondary Prevention of Ischemic Stroke

Anti-Platelet Therapy
- **primary prevention**
  - current evidence has not firmly established a protective role for antiplatelet agents for low-risk patients without a prior stroke/TIA
- **secondary prevention**
  - ASA is the initial antiplatelet of choice for stroke prevention
  - other agents (generally reserved for those who suffer cerebrovascular symptoms while on ASA or in unable to tolerate ASA)
  - Aggrenox® (ESPRIT trial)
  - clopidogrel (CAPRIE trial)
  - there is no benefit (and increased risk of major bleeding) to combining ASA and clopidogrel (MATCH and CHARISMA trials)

Carotid Stenosis
- **primary prevention (asymptomatic)**
  - carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per year; carotid endarterectomy reduces the risk of stroke by 1% per year (but 5% risk of complications)
- **secondary prevention (previous stroke/TIA in carotid territory)**
  - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), and is less beneficial for those with symptomatic moderate stenosis (50-69%) (NASCET trial), see Neurosurgery, NS25
- according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI and death. However, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

Atrial Fibrillation
- primary and secondary prevention with anticoagulation
  - risk stratification using CHADS2 score (see sidebar)
  - 0 (very low risk): antiplatelet
  - 1 (low risk): anticoagulant or antiplatelet – patient specific decision
  - >2 (mod-high risk): anticoagulant
  - anticoagulation therapy
  - warfarin (titrate to INR 2-3)
  - dabigatran (110 or 150 mg bid) may be an option to warfarin, but should be used cautiously due to lack of a reversal agent should bleeding occur

Hypertension
- **primary prevention**
  - targets: BP <140/90 (or <130/80 for diabetics or renal disease)
  - ramipril 10 mg PO OD is effective in patients at high risk for cardiovascular disease (HOPE trial)
  - ACEI reduce the risk of stroke beyond their antihypertensive effect
- **secondary prevention**
  - ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

Hypercholesterolemia
- **primary prevention**
  - statins reduce the risk of stroke in patients with CAD or at high risk for cardiovascular events, even with normal cholesterol (CARE trial)
- **secondary prevention**
  - statins reduce risk of subsequent stroke – best evidence is for high dose atorvastatin (SPARCL trial) but lower doses may be more appropriate if patient cannot tolerate high dose

Diabetes
- ideal management: HbA1c <7%, fasting blood glucose between 4 and 7

Smoking
- **primary prevention**
  - smoking increases risk of stroke in a dose-dependent manner
- **secondary prevention**
  - after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

Ischemic Stroke
**Primary and Secondary Prevention of**

High-dose Atorvastatin after Stroke or Transient Ischemic Attack (SPARCL trial)
NEJM 2003;359:549-559
Method: Multicenter double-blind RCT
Population: 4731 patients with stroke or TIA within 1-4 mo before study entry, LDL 100-190 mg/dl, no coronary heart disease.
Intervention: 80 mg atorvastatin PO OD or placebo.
Outcome: Final non-fatal or fatal stroke over 5 yr
Results: Patients receiving atorvastatin had a lower rate of stroke (ARI 2.2%, hazard ratio 0.84; P = 0.003). There was a five-year absolute reduction in risk of 3.5% (95% CI: 0.02-0.16). There was no significant change in mortality rate, but a small significant increase in the risk of hemorrhage.
Conclusions: High-dose atorvastatin decreases overall incidence of strokes and cardiovascular events in patients with a history of recent stroke or TIA.

Dabigatran vs. Warfarin in Patients with Atrial Fibrillation (The RE-LY Trial)
NEJM 2011;365:898-907
Study Type: Prospective, multi-center RCT. Double-blinded comparison between dabigatran and warfarin.
Population: 18,113 patients with atrial fibrillation and a risk of stroke followed over 2 yr.
Primary Outcome: Stroke or systemic embolism.
Results: Rates of outcome were 1.69% per year in warfarin group and a 1.53% per year in dabigatran group (RR 0.87, P = 0.003). Risk of hemorrhagic stroke was lower with dabigatran (0.12% versus 0.38%; P <0.001). Minor bleeds were slightly increased in warfarin group (3.66% versus 2.71% with dabigatan; P = 0.033). Risk of hemorrhagic stroke was lower with dabigatran (0.12% versus 0.38%; P <0.001). Conclusions: Dabigatan at 110 mg PO bid was associated with similar rates of stroke and systemic embolism and lower rates of major hemorrhage compared to warfarin in patients with atrial fibrillation. The 150 mg PO bid dose of dabigatran was more effective at stroke prevention and had a similar bleeding risk to warfarin.

tPA in Acute Stroke – NINDS Trial
NEJM 1995;333:1581-1588
Study: Randomized, double-blind, placebo-controlled trial (3 mo follow-up).
Patients: 624 patients (mean age 79 yr) with ischemic stroke of recent onset, and no evidence of intracranial hemorrhage on CT. Exclusions included hx of recent stroke or recent surgery, DBP >185, DBP >110, symptoms of SAH, recent GI or GU hemorrhage, seizure with onset of stroke, and recent use of anticoagulants.
Intervention: IV tPA or placebo within 180 min of the onset of symptoms.
Outcomes: Neurologic deficit at 24 h (NIHSS scale) and functional outcome at 3 mo.
Results: There was no significant difference between groups at 24 h. At 3 mo, there were more patients in the tPA group with minimal or no disability (52% vs. 38%, P = 0.03). Intracranial hemorrhage was more common in the tPA group (p=0.001). There was no difference in mortality.
Conclusion: IV tPA given within 3 h of onset of acute ischemic stroke improves functional outcome at 3 mo. The risk of hemorrhage is increased.

Dr. et al. Neurology, 2014
Physical Activity
- regular physical activity is an important lifestyle measure in stroke prevention and its beneficial effect has a dose-related response in terms of intensity and duration of activity

Stroke Rehabilitation
- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

Cerebral Hemorrhage

Investigations
- general investigations, see Assessment and Treatment of Ischemic Stroke, N44
- further investigations:
  - lumbar puncture (if suspect subarachnoid hemorrhage despite negative CT)
  - may require cerebral angiogram if suspect aneurysm or AVM
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion
- surgical: see Neurosurgery, NS7

Management
- medical
  - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2010 AHA/ASA guidelines suggest that reducing sBP to as low as 140 mmHg with IV anti-hypertensives is safe and appropriate management (target BP 140-160 systolic)
  - ICP lowering medical management (if necessary): see Neurosurgery, NS7

Multiple Sclerosis (MS)

Definition
- a chronic inflammatory disease of the CNS characterized by relapsing remitting, or progressive neurologic symptoms due to inflammation, demyelination and axonal degeneration

Clinical Patterns of MS (Figure 25)
- relapsing remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- most RRMS goes on to become SPMS

MS Variants
- Devic’s = neuromyelitis optica (NMO): severe optic neuritis and extensive transverse myelitis extending >3 vertebral segments (NMO antibody positive)
- clinically isolated syndrome (CIS): single MS-like episode, which may progress to MS
- tumefactive MS: solitary lesion >2 cm mimicking neoplasms on MRI
- fulminant MS (Marburg): rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- acute disseminated encephalomyelitis (ADEM): monophasic demyelinating disorder with multifocal neurologic symptoms seen mainly in children often following infection or vaccination

Etiology
- genetic
  - polygenetic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
  - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- environmental
  - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, SE Australia)
  - MS has also been linked to certain viruses (EBV is associated with MS)

Epidemiology
- onset 17-35 yr; 3F:1M
- PPMS occurs in an older population with 1F:1M
Diagnosis
- dissemination in space and in time as based on the revised McDonald criteria
- dissemination in time: 2 or more attacks, new gadolinium enhancing lesion 3 mo later, or new T2 lesions >1 mo after first attack
- dissemination in space: clinical evidence of 2 or more lesions; or three of [1 gadolinium enhancing or 9 T2 lesions], [1 infratentorial lesion], [1 juxtacortical lesion], [3 periventricular lesions]

Clinical Features
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gait, vertigo, bladder dysfunction
- Lhermitte's sign: flexion of neck causes electric shock sensation down back into limbs indicating cervical cord lesion
- Uhthoff's phenomenon: worsening of symptoms (classically optic neuritis) in heat
- SPMS: classically weakness of legs in pyramidal distribution paired with cerebellar findings of arms (i.e. intention tremor)
- symptoms not commonly found in MS: visual field defects, aphasia, apraxia, progressive hemiparesis
- relapse: acute/subacute onset of clinical dysfunction that peaks from days to weeks, followed by remission with variable symptom resolution (symptoms must last at least 24 h)
- in RRMS, average 0.4 to 0.6 relapses/yr, but higher disease activity in first year of disease

Investigations
- MRI: demyelinating plaques appear as hyperintense lesions on T2 weighted MRI, with active lesions showing enhancement with gadolinium
- typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxta cortical region, and dorsolateral spinal cord
- Dawson's fingers: periventricular lesions extending into corpus callosum
- cranial MRI is more sensitive than spinal MRI
- CSF: oligoclonal bands in 90%, increased IgG concentration
- evoked potentials (visual/auditory/somatosensory): delayed but well-preserved wave forms

Treatment
- acute treatment: methylprednisolone 1000 mg IV daily x 3-7 d (no taper required); if poor response to corticosteroids may consider plasma exchange
- disease modifying therapy (DMT):
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: interferon-β (injection: Betaseron®, Avonex®, Rebif®), glatiramer acetate (injection: Copaxone®)
  - second line: natalizumab (Tysabri®) (monthly IV infusion)
  - new oral agents: fingolimod (available) and cladribine (not yet available)
  - indications for fingolimod: newly diagnosed patients with active RRMS who prefer oral treatment despite increased risks or those intolerant of first line therapies
  - CIS: early treatment with interferons may delay potential second attack
  - RRMS: DMT reduces rate of relapse by about 30%
  - PPMS/SPMS: no proven efficacy of DMTs
- symptomatic treatment
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantidine, modafinil, methylphenidate
  - depression: antidepressant, lithium
  - constipation: high fibre intake, stool softener, laxatives
  - sexual dysfunction: sildenafil, tadalafil, vardenafil
- education and counseling: MS society, support groups, psychosocial issues

Prognosis
- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

</table>

ICP/Volume Relationship

- adult skull is rigid with a constant intracranial volume
- contents (CSF, blood, brain) are incompressible
- increase in one constituent/space-occupying lesion = increase in ICP
- however, ICP does not rise initially due to compensatory mechanisms (autoregulation):
  - immediate: displacement of CSF to lumbar theca, displacement of blood from venous sinuses
  - delayed: displacement of ECF or ICF, displacement of brain tissue into compartments under less pressure (herniation)
- once compensation is exhausted, ICP rises exponentially

Cerebral Blood Flow (CBF)

- CBF depends on cerebral perfusion pressure (CPP) and cerebral vascular resistance (CVR)
- normal CPP >50 mmHg in adults
- cerebral autoregulation maintains constant CBF by compensating for changes in CPP, unless:
  - high ICP such that CPP <60 mmHg
  - MAP >150 mmHg or MAP <50 mmHg
  - brain injury: e.g. SAH, severe trauma
ICP Measurement

- normal ICP <15 mmHg (8-18 cm H₂O) for adult, 3-7 mmHg (4-9.5 cm H₂O) for child; varies with patient position
  - moderate elevation: increase in mean pressure >20 mmHg
  - severe elevation: increase in mean pressure >40 mmHg
- waveform: comprised of respiratory and cardiac pulsations (Traube-Hering waves); the amplitude increases with ICP
  - β-waves: coarse, variably increased amplitude, frequency ½-2/min, often related to respiration
  - plateau waves: elevation of ICP over 50 mmHg lasting 5-20 min, precursor of further deterioration

Acute Monitoring
- lumbar puncture (LP) (see sidebar)
- intraventricular catheter/ventriculostomy/external ventricular drain (EVD) (“gold standard”, also permits therapeutic drainage of CSF to decrease ICP)

Chronic Monitoring
- fibre optic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

Elevated ICP

Etiology
- intracranial space-occupying lesion:
  - tumour
  - pus
  - blood [trauma → hematoma (most common), subarachnoid hemorrhage]
  - depressed skull fracture
  - foreign body
- increased intracranial blood volume
  - vasodilatation (increased pCO₂/decreased pO₂/decreased extracellular pH, e.g. hypoventilation)
  - venous outflow obstruction (venous sinus thrombosis, superior vena cava syndrome, space occupying lesion)
  - cranial dependency
- cerebral edema
  - vasogenic (vessel damage, e.g. hypertensive encephalopathy, tumour)
  - cytotoxic (tissue/cell death, e.g. hypoxia, brain injury)
  - osmotic (acute hyponatremia, hepatic encephalopathy)
- impaired autoregulation (hypotension, hypertension, brain injury)
- hydrocephalus (obstructive, non-obstructive)
- tension pneumocephalus (gas within the cranial cavity)
- pseudotumour cerebri (idiopathic intracranial hypertension)
- status epilepticus (chronic seizure resulting in brain edema)

Clinical Features
1. Acute Elevated ICP
   - headache (H/A): worse in the morning, aggravated by stooping and bending
   - nausea and vomiting (N/V)
   - decreased level of consciousness (LOC) if ICP = diastolic BP, or midbrain compressed
   - drop in GCS = best index to monitor progress and predict outcome of acute intracranial process (see Neurotrauma, NS30)
   - papilledema ± retinal hemorrhages (may take 24-48 h to develop)
   - abnormal extra-ocular movements (EOM):
     - CN VI palsy: often falsely localizing (causative mass may be remote from nerve)
     - upward gaze palsy (especially in children with obstructive hydrocephalus)
   - herniation syndromes (see Herniation Syndromes, NS7)
   - focal signs/symptoms due to lesion

2. Chronic Elevated ICP
   - H/A
     - postural: worsened by coughing, straining, bending over
     - morning/evening H/A → vasodilatation due to increased CO₂ with recumbency

Blood Brain Barrier
- Infarction/neoplasm → destroy tight junctions → vasogenic edema
- Cushing’s Triad of Acute Raised ICP (full triad seen in 1/3 of cases)
  - Hypertension
  - Bradycardia (late finding)
  - Irregular respiratory pattern

Lumbar puncture is contraindicated with known/suspected intracranial mass.
visual changes
- due to papilledema
- enlarged blind spot, if advanced → episodic constrictions of visual fields (“grey-outs”)
- optic atrophy/blindness
- differentiate from papillitis (usually unilateral with decreased visual acuity)
- decreased level of consciousness

**Investigations**
- patients with suspected elevated ICP require an urgent CT/MRI
- ICP monitoring where appropriate

### Table 3. Herniation Syndromes

<table>
<thead>
<tr>
<th>Herniation Syndrome</th>
<th>Definition</th>
<th>Etiology</th>
<th>Clinical Features</th>
</tr>
</thead>
</table>
| 1. Subfalcine       | Cingulate gyrus herniates under falx | Lateral supratentorial lesion | Usually asymptomatic
|                     |            |          | Wors of impending transentorial herniation |
|                     |            |          | Risk of ACA compression |
| 2. Central Tentorial (Axial) | Displacement of diencephalon through tentorial notch | Supratentorial midline lesion | Small pupils, moderately dilated, fixed (rostral to caudal deterioration), sequential failure of diencephalon, medulla |
|                     |            | Diffuse cerebral swelling | Decreased LOC (midbrain compression) EOM/ upward gaze impairment (“sunset eyes”): compression of pretectum and superior colliculi |
|                     |            | Late uncal herniation | Brainstem hernorrhage (“Duret’s” = secondary to shearing of basilar artery perforating vessels) |
|                     |            |          | Diabetes insipidus (traction on pituitary stalk and hypothalamus), end-stage sign |
| 3. Lateral Tentorial (Uncal) | Uncus of temporal lobe herniates down through tentorial notch | Lateral supratentorial lesion (often rapidly expanding traumatic hematoma) | Ipsilateral non-reactive dilated pupil (earliest, most reliable sign) → ipsilateral EOM paralysis, ptosis (CN III compression) |
|                     |            |          | Decreased LOC (midbrain compression) |
|                     |            |          | Contralateral hemiplegia ± extensor (upgoing) plantar response ± ipsilateral hemiplegia (“Kernohan’s notch” – a false localizing sign resulting from pressure from the edge of the tentorium on the contralateral cerebral peduncle) |
| 4. Upward           | Cerebellar vermis herniates through tentorial incisura | Large posterior fossa mass (common after VP shunting) | Cerebellar infarct (superior cerebellar artery (SCA) compression) |
|                     |            |          | Hydrocephalus (cerebral aqueduct compression) |
| 5. Tonsillar        | Cerebellar tonsils herniate through foramen magnum | Infratentorial lesion | Neck stiffness and head tilt (tonsillar impaction) |
|                     |            | Following central tentorial herniation | Decreased LOC (midbrain compression) |
|                     |            | Following LP in presence of intracranial mass lesion | Flaccid paralysis |
|                     |            |          | Respiratory irregularities, respiratory arrest (compression of medullary respiratory centres) |
|                     |            |          | Blood pressure instability (compression of medullary cardiovascular centres) |

**Treatment of Elevated ICP**
- CT or MRI to identify etiology, assess for midline shift/herniation
- treat primary cause (i.e. remove mass lesions, ensure adequate ventilation)
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
- goals: keep ICP <20 mmHg, CPP >65 mmHg, MAP >90 mmHg

**Conservative Measures**
- elevate head of bed at 30°, maintain neck in neutral position → increases intracranial venous outflow with minimal effect on arterial pressure
- prevent hypotension with fluid and vaspressors, dopamine, norepinephrine prn
- ventilate to normocarbia (pCO₂ 35-40 mmHg) → prevents vasodilatation
- oxygen to maintain pO₂ >60 mmHg → prevents hypoxic brain injury
- osmolar diuresis (mannitol 20% IV solution 1-1.5 g/kg, then 0.25 g/kg q6h to serum osmolarity of 315-320)
  - can give rapidly, acts in 15-30 min, must maintain sBP >90 mmHg
- corticosteroids → decrease edema over subsequent days around brain tumour, abscess, blood
  - no proven value in head injury or stroke
**Aggressive Measures**
- sedation ("light" e.g. barbiturates/codeine → "heavy" e.g. fentanyl/MgSO4)
- paralysis with vecuronium → reduces sympathetic tone, reduces HTN induced by muscle contraction
- hyperventilate to pCO$_2$ 30-35 mmHg
  - use for brief periods only – also results in decreased cerebral blood flow
- drain 3-5 mL CSF via ventricles, assess each situation independently
- insert EVD (if acute) or shunt
- barbiturate-induced coma induced with pentobarbital to reduce cerebral blood flow and metabolism (10 mg/kg over 30 min, then 1 mg/kg q1h continuous infusion)
  - decreases mortality, but no improvement in neurological outcome
- decompressive craniectomy is a last resort
- no role for the use of hypothermia in head injury

---

**Hydrocephalus**

- hydrocephalus in children, see *Pediatric Neurosurgery, NS36*

**Definition**
- increased CSF volume

**Etiology**
- obstruction to CSF flow
- decreased CSF absorption
- increased CSF production (rarely) – e.g. choroid plexus papilloma (0.4-1% of intracranial tumours)

**Epidemiology**
- estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2/1000 live births

**Classification**

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Definition</th>
<th>Etiology</th>
<th>Findings on CT/MRI</th>
</tr>
</thead>
</table>
| Obstructive (Non-Communicating) Hydrocephalus | Circulation blocked within ventricular system proximal to the arachnoid granulations | Acquired
  - Aqueductal stenosis (adhesions following infection, hemorrhage)
  - Intraventricular lesions (tumours e.g. 3rd ventricle colloid cyst, hematomas)
  - Mass causing tentorial herniation, aqueduct/4th ventricle compression
  - Others: neurosarcoïdosis, abscess/granulomas, arachnoid cysts | Ventricular enlargement proximal to block
  - Periventricular hypodensity (transpensional migration of CSF forced into extracellular space)
  - Sulcal effacement |
| Congenital | Aqueductal stenosis, Dandy-Walker malformation, Chiari malformation (see *Pediatric Neurosurgery, NS37*) | | |
| Non-Obstructive (Communicating) Hydrocephalus | CSF absorption blocked at extraventricular site = arachnoid granulations | Post-infectious (#1 cause)
  - meningitis, cysticercosis
  - Post-hemorrhagic (#2 cause) → SAH, IVH, traumatic
  - Choroid plexus papilloma (rare, causes increased CSF production)
  - Idiopathic → normal pressure hydrocephalus | All ventricles dilated |
| Normal Pressure Hydrocephalus (NPH) | Persistent ventricular dilatation in the context of normal CSF pressure | Idiopathic (50%)
  - Others: subarachnoid hemorrhage, meningitis, trauma, radiation-induced | Enlarged ventricles without increased prominence of cerebral sulci |
| Hydrocephalus Ex Vacuo | Ventricular enlargement resulting from atrophy of surrounding brain tissue | Normal aging
  - Alzheimer’s, Creutzfeldt-Jacob Disease | Enlarged ventricles and sulci
  - Cerebral atrophy |

**Figure 8. The flow of CSF**

CSF produced by choroid plexus, flows to: ventricles → foramina of Luschka (lateral) and Magendie (medial) → subarachnoid space → absorbed by arachnoid villi/granulations into venous sinuses.

CSF production = CSF reabsorption = $-500$ mL/d in normal adults

Normal CSF volume = 150 mL (50% spinal, 50% intracranial = 25 mL intraventricular, 50 mL subarachnoid)
Clinical Features
- acute hydrocephalus
  - signs and symptoms of acute elevated ICP (see Elevated ICP, NS6)
  - impaired upward gaze (“sunset eyes”) and/or CN VI palsy
- chronic/gradual onset hydrocephalus (i.e. NPH)
  - gradual onset of classic triad developing over weeks or months
    - pressure of ventricle on LE motor fibres → gait disturbance (ataxia and apraxia usually initial symptoms)
    - pressure on cortical bowel/bladder centre → urinary incontinence
    - pressure on frontal lobes → dementia
  - CSF pressure can be measured within clinically “normal” range

Investigations
- CT/MRI (periventricular lucency suggests raised CSF pressure)
- ultrasound (through anterior fontanelle in infants)
- ICP monitoring (e.g. LP) may be used to investigate NPH, test response to shunting (lumbar tap test)
- radionuclide cisternography can test CSF flow and absorption rate (unreliable)
- β-2 transferrin assay to test for the presence of CSF leak

Treatment
- ventricular drainage
  - surgical removal of obstruction (if possible) or excision of choroid plexus papilloma
- shunts
  - ventriculoperitoneal (VP): most common
  - ventriculopleural
  - ventriculo-atrial (VA): relatively increased risk of infections, shunt emboli
  - lumboperitoneal: for communicating hydrocephalus and pseudotumour cerebri
- third ventriculostomy (for obstructive hydrocephalus) via ventriculoscopy
- LPs for transient hydrocephalus (e.g. SAH), IVH in premature infants, etc.

</table>
**Idiopathic Intracranial Hypertension (Pseudotumour Cerebri)**

**Definition**
- raised intracranial pressure and papilledema without evidence of any mass lesion, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)

**Etiology**
- unknown (majority), but associated with:
  - lateral venous sinus thrombosis
  - habitus/diet: obesity, hyper/hypovitaminosis A
  - endocrine: reproductive age, menstrual irregularities, Addison’s/Cushing’s disease, thyroid irregularities
  - hematological: iron deficiency anemia, polycythemia vera
  - drugs: steroid administration or withdrawal, tetracycline, nalidixic acid, etc.
- risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones (“fat, female, fertile, forties”)

**Epidemiology**
- incidence ~0.5/100,000 per year
- usually in 3rd and 4th decade (F>M)

**Clinical Features**
- symptoms and signs of raised ICP (H/A in >90%, pulsatile intracranial noise), but no LOC or diplopia
- decreased visual acuity, papilledema, visual field defect, optic atrophy (key morbidity)
- usually self-limited, recurrence is common, chronic in some patients
- risk of blindness is not reliably correlated to symptoms or clinical course

**Investigations**
- CT: normal
- CSF studies: normal
- MRI: must look for venous sinus thrombosis

**Treatment**
- rule out conditions that cause intracranial hypertension (especially sinus thrombosis)
- discontinue offending medications, encourage weight loss, fluid/salt restriction
- pharmacotherapy: acetazolamide (decreases CSF production), thiazide diuretic or furosemide
- if above fail: serial LPs, shunt
- optic nerve sheath decompression (if progressive impairment of visual acuity)
- 2-yr follow-up with imaging to rule out occult tumour, ophthalmology follow-up

**Tumours**

**Ventricular:** colloid cyst, choroid plexus papilloma, ependymoma, germinoma, teratoma, meningioma

**Supratentorial extra-axial:** meningioma, cysts

**Supratentorial intra-axial:** astrocytoma, glioblastoma, oligodendroglioma, ganglioma, lymphoma, metastases

**Posterior fossa intra-axial:** schwannoma, meningioma, cysts, metastases

**Posterior fossa extra-axial:** schwannoma, meningioma, cyst, metastases

**Skull base:** carcinoma, chordoma, glomus jugulare, estoma

**Sellar or suprasellar:** pituitary edema, craniohypophyseoma, optic nerve glioma, cyst

**Important Features to Note on CT and MRI (≥ contrast enhancement)**
- Lesions (= edema, necrosis, hemorrhage)
- Midline shifts and herniations
- Effacement of ventricles and sulci (often ipsilateral), basal cisterns
- Single or multiple (multiple implies metastasis)

**DDx for Ring Enhancing Lesion on CT with Contrast**

**MAGICAL DR**
- Metastases*
- Abscess*
- Glioblastoma (high grade astrocytoma)*
- Infarct
- Contusion
- AIDS (toxoplasmosis)
- Lymphoma
- Demyelination
- Resolving hematoma
- (*) 3 most common Dxs

**Primary Sources of Metastatic Brain Tumours**
- Lung 44%
- Breast 10%
- Kidney (RCC) 7%
- GI 6%
- Melanoma 3%
Classification
- primary vs. metastatic, intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. pediatric
- benign: non-invasive, devastating due to expansion of mass in fixed volume of skull (mass effect)
- malignant: implies rapid growth, invasiveness, but rarely extracranial metastasis
- types of intracranial tumours (* = most common)
  - neuroepithelial tissue
    - astrocytic tumours: astrocytoma, glioblastoma
    - oligodendrogial tumours
    - oligoastrocytic tumours
    - neuronal and mixed neuronal-glial tumours: gangliocytoma, ganglioglioma, neurocytoma, neuroblastoma
    - embryonal tumours: medulloblastoma, neuroectodermal
    - other: pineal, ependymal, and choroid plexus tumours
  - meningial: meningiomas*, mesenchymal, hemangioblastomas
  - cranial and parasellar nerves: schwannoma, neurofibroma
  - lymphomas and hematopoietic neoplasms
  - germ cell: germinomas, teratomas
  - pituitary adenomas*
  - sellar region: craniopharyngiomas, spindle cell oncocytoma
  - cysts: epidermoid/dermoid cysts, colloid cysts
  - local extension: chordomas, glomus jugulare tumours
  - metastatic tumours

Clinical Features
- progressive neurological deficit (70%): usually motor weakness, ± CN deficits, sensory, cognitive, personality, endocrine deficits (these may localize lesion)
- H/A (50%) ± symptoms of elevated ICP (see Elevated ICP, NS6)
- N/V (40%)
- seizures (25%)
- papilledema, vision changes
- symptoms suggestive of TIA (ictal, post-ictal, or ischemic 2o to “steal phenomenon”)
- rarely presents with hemorrhage
- familial syndromes associated with CNS tumours
  - von Hippel-Lindau (hemangioma)
  - tuberous sclerosis (astrocytoma)
  - neurofibromatosis type 1 and 2 (astrocytoma, acoustic neuroma respectively)
  - Li-Fraumeni (astrocytoma)
  - Turcot syndrome (glioblastoma multiforme)
  - multiple endocrine neoplasia type 1 (MEN-1) (pituitary adenoma)

Investigations
- CT, MRI, stereotactic biopsy (tissue diagnosis), metastatic work-up

Treatment
- conservative: serial Hx, Px, imaging for slow growing/benign lesions
- medical: corticosteroids to reduce cytotoxic cerebral edema, pharmacological conservative: serial Hx, Px, imaging for slow growing/benign lesions
- surgical: total or partial excision (decompressive, palliative), shunt if hydrocephalus
- radiotherapy: conventional fractionated radiotherapy (XRT), stereotactic radiosurgery (e.g. Gamma Knife*)
- chemotherapy: e.g. alkylating agents (temozolomide)

Table 6. Tumour Types: Age, Location

<table>
<thead>
<tr>
<th>Age</th>
<th>Supratentorial</th>
<th>Infratentorial (posterior fossa)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;15 yr</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  - Incidence: 2.5-100,000/yr
  - 60% infratentorial
  - Astrocytoma (all grades) (50%) | Medulloblastoma (15-20%)
  - Cerebellar astrocytoma (15%) |
  - Others: pineal region tumours, choroid plexus tumours, ganglioglioma, DNET | Ependymoma (9%)
  - Brainstem astrocytoma |
| >15 yr |
  - 80% supratentorial
  - High grade astrocytoma (12-15%, e.g. GBM) | Metastasis
  - Metastasis (15-30%, includes infratentorial)
  - Meningioma (15-20%) |
  - Low grade astrocytoma (8%) | Acoustic neuroma (schwannoma) (5-10%)
  - Pituitary adenoma (5-8%)
  - Oligodendroglioma (5%)
  - Other: colloid cyst, CNS lymphoma, dermoid/epidermoid cysts | Hemangioblastoma (2%)
  - Meningioma |

Primary Brain Tumours
- Rarely undergo metastasis
- Adults = mostly supratentorial
- Children = mostly infratentorial

Brain Metastasis
- 1/3 of all adult brain tumours
- Well circumscribed, often at grey-white matter junction

Management of Single Brain Metastasis: A Practice Guideline

Carr Oncol 2007;14:131-143

Background: In Ontario the benefits of surgical resection ± adjuvant whole-brain radiation therapy (WBRT) or stereotactic radiosurgery (SRS) in confirmed single brain metastasis are summarized in this manuscript.

Methods: Medline, Cancerlit, Embase and Cochrane Library databases as well as abstracts published in the proceedings of the annual meetings of the American Society of Clinical Oncology (1997-2005) and American Society for Therapeutic Radiology and Oncology (1998-2004) were systematically searched for relevant evidence. Outcomes were compared in terms of survival, local control of disease, quality of life, and adverse effects. The final review of these works was condensed into a practice guideline approved by the Neuro-oncology DSG and Ontario practitioners (through an electronic survey).

Results: Two of three RCTs reported a significant survival benefit for patients with single brain metastasis who underwent surgical resection as compared with those who received WBRT alone. The RCT that compared surgical resection plus WBRT with surgical resection alone reported no significant difference in overall survival or length of functional independence; however, tumour recurrence at the site of the metastasis and anywhere in the brain was less frequent in patients who received WBRT as compared with patients in the observation group. In addition, patients who received WBRT were less likely to die from neurologic causes. Results of the RCT that compared WBRT and SRS with WBRT alone indicated a significant improvement in median survival in patients who received SRS.

Conclusions: Surgical excision should be considered for patients with good performance status, minimal or no evidence of extracranial disease, and a surgically accessible single brain metastasis amenable to complete excision. Furthermore, to reduce the risk of tumour recurrence postoperative WBRT should be considered. As an alternative to surgical resection, WBRT followed by SRS boost should be considered, however, the evidence is insufficient to recommend SRS alone as a single-modality therapy.

### Metastatic Tumours

- most common brain tumour seen clinically
- 15-30% of cancer patients present with cerebral metastatic tumours
  - most common sources: lungs, breast
  - other sources: kidney, thyroid, stomach, prostate, testis, melanoma
- hematogenous spread most common

### Location

- 80% are hemispheric, often at grey-white matter junction or junction of temporal-parietal-occipital lobes (likely emboli spreading to terminal MCA branches)

### Investigations

- identify primary tumour
  - metastatic work-up (CXR, CT chest/abdo, abdominal U/S, bone scan, mammogram)
  - CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
  - MRI more sensitive, especially for posterior fossa
  - consider biopsy in unusual cases, or if no primary identified

### Treatment

- medical
  - phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
  - dexamethasone to reduce edema given with ranitidine
  - chemotherapy (e.g. small cell lung cancer)

---

![Figure 10. Multiple brain metastases (see arrows)](image-url)
• radiation
  ▪ stereotactic radiosurgery: for discrete, deep-seated/inoperable tumours
  ▪ multiple lesions: use whole brain radiation therapy (WBRT); consider stereotactic
  radiosurgery if <3 lesions
  ▪ post-op WBRT is commonly used
• surgical
  ▪ single/solitary lesions: use surgery + radiation

**Prognosis**
• median survival without treatment once symptomatic is ~1 mo, with optimal treatment
  6-9 mo but varies depending on primary tumour type

## Astrocytoma

• most common primary intra-axial brain tumour, common in 4-6th decades

### Table 8. Astrocytoma Grading System

### Clinical Features
• sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
• symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

### Investigations
• CT/MRI with contrast: variable appearance depending on grade (see Table 8)
• tissue biopsy: WHO grade and histology correlates with prognosis, but 25% chance of sampling error due to tumour heterogeneity

### Treatment
• low grade diffuse astrocytoma
  ▪ close follow-up, radiation, chemotherapy, surgery all valid options
  ▪ surgery: not curative, trend towards better outcomes
  ▪ radiotherapy alone or post-op prolongs survival (retrospective evidence)
  ▪ chemotherapy: usually reserved for tumour progression
• high grade astrocytomas (anaplastic astrocytoma and GBM)
  ▪ surgery
    ▪ gross total resection: maximal safe resection + fractionated radiation with 2 cm margin +
      concomitant and adjuvant temozolomide
      ▪ except: extensive dominant lobe GBM, significant bilateral involvement, end of life
        near, extensive brainstem involvement
    ▪ stereotactic biopsy if resection not possible, followed by fractionated radiation with 2 cm
      margin
  ▪ expectant (based on functional impairment – Karnofsky score <70; patient’s/family’s wishes)
  ▪ aim to prolong “quality” survival
  ▪ chemotherapy: ~20% response rate, temozolomide (agent of choice); better response to
temozolomide predicted by MGMT gene hypermethylation
• multiple gliomas: WBRT ± chemotherapy

## Meningioma

• mostly benign (1-2% anaplastic), slow-growing, extra-axial, circumscribed (non-infiltrative),
arise from arachnoid membrane
• often calcified, cause hyperostosis of adjacent bone
• classically see Psammoma bodies on histology
• common locations: parasagittal convexity or falx (70%), sphenoid wing, tuberculum sellae,
  foramen magnum, olfactory groove

### Clinical Features
• middle aged, slight female preponderance (M:F = 2:3), high progesterone receptors (increase in
  size with pregnancy), symptoms of increased ICP, focal deficits, usually solitary (10% multiple,
  likely with loss of NF2 gene/22q12 deletion)
Investigations
- CT with contrast: homogeneous, densely enhancing, along dural border ("dural tail"), well circumscribed (Figure 12)
- contrast enhanced MRI provides better detail
- angiography
  - most are supplied by external carotid feeders (meningeal vessels)
  - also assesses venous sinus involvement, "tumour blush" commonly seen (prolonged contrast image)
- octreotide scintigraphy: to establish if expression of somatostatin receptor

Treatment
- conservative management for non-progressive, asymptomatic lesions
- surgery is treatment of choice if symptomatic or progression on sequential imaging (curative if complete resection)
- SRS may be an option for lesions <3 cm
- endovascular embolization to facilitate surgery
- SRS or XRT for recurrent atypical/malignant meningiomas

Prognosis
- >90% 5-yr survival, recurrence rate variable (often ~10-20%)
- depends on extent of resection (Simpson’s classification)

Vestibular Schwannoma (Acoustic Neuroma)
- slow-growing (average of 1 mm/yr), benign posterior fossa tumour
- arises from vestibular component of CN VIII in internal auditory canal, expanding into bony canal and cerebello-pontine angle (CPA)
- if bilateral, diagnostic of neurofibromatosis type II
- epidemiology: all age groups affected, peaks at 4th-6th decades

Clinical Features
- compression of structures in CPA, often CN VIII (hearing loss 98%, tinnitus, dysequilibrium), followed by CN V and VII
- ataxia and raised ICP are late features

Investigations
- MRI with gadolinium or T2 FIESTA sequence (>98% sensitive/specific), CT with contrast 2nd choice
- audiogram, brainstem auditory evoked potentials, caloric tests

Treatment
- conservative: serial imaging
- radiation: stereotactic radiosurgery or fractionated radiotherapy
- surgery if: lesion >3 cm, brainstem compression, edema, hydrocephalus
  - curable if complete resection (almost always possible)
  - operative complications: CN VII, VIII dysfunction (only significant disability if bilateral), CSF leak

Pituitary Adenoma
- primarily from anterior pituitary, 3rd-4th decades, M=F
- incidence in autopsy studies approximately 20%
- classification
  - microadenoma <1 cm; macroadenoma ≥1 cm
  - endocrine active (functional/secretory) vs. inactive (non-functional)
- differential: parasellar tumours (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm

Clinical Features
- mass effects
  - H/A
  - bitemporal hemianopsia (compression of optic chiasm) (see Neurology, N12 for details of visual field deficit)
  - CN III, IV, V<sub>1</sub>, V<sub>2</sub>, VI palsy (compression of cavernous sinus)
- endocrine effects
  - hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido
  - ACTH production: Cushing’s disease, hyperpigmentation
  - GH production: acromegaly/gigantism
  - panhypopituitarism (hypothyroidism, hypoadrenalism, hypogonadism)
  - associated MEN-1 syndrome
  - diabetes insipidus
- pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
  - abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, and panhypopituitarism
  - CSF rhinorrhea and seizures (rare)
  - signs and symptoms of subarachnoid hemorrhage (rare)

Investigations
- formal visual fields, CN testing
- endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose, FSH/LH, IGF-1), electrolytes, urine electrolytes, and osmolarity
- imaging (MRI with and without contrast)

Treatment
- medical
  - for apoplexy: rapid corticosteroid administration ± surgical decompression
  - for prolactinoma: dopamine agonists (e.g. bromocriptine)
  - for Cushing’s: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
  - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
  - endocrine replacement therapy
- surgical
  - trans-sphenoidal, trans-ethmoidal, trans-cranial approaches for non-secreting adenomas causing mass effect and Cushing/acromegaly (50% cure rate)

Pus

Sources of Pus/Infection
- four routes of microbial access to CNS
  1. hematogenous spread (most common): arterial and retrograde venous
     - adults: chest is #1 source (lung abscess, bronchiectasis, empyema)
     - children: congenital cyanotic heart disease with R to L shunt
     - immunosuppression (AIDS – toxoplasmosis)
  2. direct implantation (dural disruption)
     - trauma
     - iatrogenic (e.g. following LP post-op)
     - congenital defect (e.g. dermal sinus)
  3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site (e.g. otitis media, mastoiditis, sinusitis, osteomyelitis, dental abscess)
  4. spread from PNS (e.g. viruses: rabies, herpes zoster)
- common examples
  - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
  - treatment: immediate drainage and antibiotics, surgical emergency if cord compression
  - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
  - treatment: surgical drainage and antibiotics, 20% mortality
  - meningitis, encephalitis (see Infectious Diseases, ID19, ID20)
  - cerebral abscess (see Cerebral Abscess, below)

Cerebral Abscess

Definition
- pus in brain substance, surrounded by tissue reaction (capsule formation)

Etiology
- modes of spread (see above): 10-60% of patients have no cause identified
- pathogens
  - Streptococcus (most common), often anaerobic or microaerophilic
  - Staphylococcus (penetrating injury)
  - Gram-negatives, anaerobes (Bacteroides, Fusobacterium)
  - in neonates: Proteus and Citrobacter (exclusively)
  - immunocompromised: fungi and protozoa (Toxoplasma, Nocardia, Candida albicans, Listeria monocytogenes, Mycobacterium and Aspergillus)
**Risk Factors**
- lung abnormalities [infection, AV fistulas; especially Osler-Weber-Rendu syndrome (aka hereditary hemorrhagic telangiectasia)]
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of micro-organisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess

**Clinical Features**
- focal neurological signs and symptoms
  - H/A, decreased LOC; hemiparesis and seizures in 50%
- mass effect, increased ICP and sequelae (cranial enlargement in children)
- hemiparesis and seizures in 50%
- ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

**Complications**
- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

**Investigations**
- CT scan often first test in emergency department (see Figure 14)
- MRI
  - imaging of choice
  - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumour (white)
- WBC/ESR may be normal, blood cultures rarely helpful and LP contraindicated if large mass
- CSF: non-specific (high ICP, high WBC, high protein, normal carbohydrate), rarely helpful, usually negative culture

**Treatment**
- aspiration ± excision and send for Gram stain, acid fast bacillus (AFB), C&S, fungal culture
- excision preferable if location suitable
- antibiotics
  - empirically: vancomycin + ceftriaxone + metronidazole or chloramphenicol or rifampin
  - 6-8 wk therapy
  - revise antibiotics when C&S known
- anti-convulsants (1-2 yr)
- follow up CT is critical (do weekly initially, more frequent if condition deteriorates)

**Prognosis**
- mortality with appropriate therapy ~10%, permanent deficits in ~50%

---

<td>Poor: 44% mortality due to cerebral herniation</td>
</tr>
</tbody>
</table>
Extradural (“Epidural”) Hematoma

Etiology
- temporal-parietal skull fracture: 85% are due to ruptured middle meningeal artery; remainder of cases are due to bleeding from middle meningeal vein, dural sinus, or bone/diploic veins

Epidemiology
- young adult, male > female = 4:1; rare before age of 2 or after age 60

Clinical Features
- classic sequence (seen in <30%): post-traumatic reduced LOC, a lucid interval of several hours, then obtundation, hemiparesis, ipsilateral pupillary dilatation, and coma
- signs and symptoms depend on severity but can include H/A, N/V, amnesia, altered LOC, HTN and respiratory distress
- deterioration can take hours to days

Investigations
- CT without contrast: “lenticular-shaped” usually limited by suture lines (see Figure 15)

Treatment
- admission, observation with serial CT indicated if all of the following are present:
  - small volume clot, minimal midline shift (MLS < 5 mm), GCS > 8, no focal deficit
  - otherwise, craniotomy to evacuate clot, follow up CT
  - mannitol pre-op if elevated ICP/brain herniation

Prognosis
- good with prompt management, as the brain is often not damaged
- worse prognosis if bilateral Babinski or decerebration pre-op
- death is usually due to respiratory arrest from uncal herniation (injury to the midbrain)

Subdural Hematoma (SDH)

ACUTE SUBDURAL HEMATOMA

Etiology
- rupture of vessels that bridge the subarachnoid space (e.g. cortical artery, large vein, venous sinus) or cerebral laceration

Risk Factors
- trauma, acceleration-deceleration injury, anti-coagulants, alcohol, cerebral atrophy, infant head trauma (see Pediatrics, P86)

Clinical Features
- no lucid period, signs and symptoms can include altered LOC, pupillary irregularity, hemiparesis

Investigations
- CT: hyperdense concave “crescentic” mass, crossing suture lines (see Figure 16)

Treatment
- craniotomy if clinically symptomatic, if hematoma > 1 cm thick, or if MLS > 5 mm (optimal if surgery < 4 h from onset); otherwise observe with serial imaging

Prognosis
- poor overall since the brain parenchyma is often injured (mortality range is 50%-90%, due largely to underlying brain injury)
- prognostic factors: initial GCS and neurologic status, post-op ICP

CHRONIC SUBDURAL HEMATOMA

Etiology
- many start out as acute SDH
- blood within the subdural space evokes an inflammatory response:
  - fibroblast invasion of clot and formation of neomembranes within days → growth of neocapillaries → fibrinolysis and liquefaction of blood clot
  - course is determined by the balance of rebleeding from neomembranes and resorption of fluid
Risk Factors
• older, alcoholics, patients with CSF shunts, anti-coagulants, coagulopathies

Clinical Features
• often due to minor injuries or no history of injury
• may present with minor H/A, confusion, language difficulties, TIA-like symptoms, symptoms of raised ICP ± seizures, progressive dementia, gait problem
• obtundation disproportionate to focal deficit; “the great imitator” of dementia, tumours

Investigations
• CT: hypodense (liquefied clot), crescentic mass (see Figure 16)

Treatment
• seizure prophylaxis only if post-traumatic seizure
• reverse coagulopathies
• burr hole drainage of liquefied clot indicated if symptomatic or thickness >1 cm; craniotomy if recurs more than twice

Prognosis
• good overall as brain usually undamaged, but may require repeat drainage

Cerebrovascular Disease

Ischemic Cerebral Infarction (80%)
• embolic, thrombosis of intracerebral arteries, vasculitis, hypercoagulability, etc.
(see Neurology, N43)

Intracranial Hemorrhage (20%)
• subarachnoid hemorrhage (SAH), spontaneous intracerebral hemorrhage (ICH), intraventricular hemorrhage (IVH)

Subarachnoid Hemorrhage (SAH)

Definition
• bleeding into subarachnoid space (intracranial vessel between arachnoid and pia)

Etiology
• trauma (most common)
• spontaneous
  ▪ ruptured aneurysms (75-80%)
  ▪ idiopathic (14-22%)
  ▪ AVMs (4-5%)
• coagulopathies (iatrogenic or primary), vasculitides, tumours, cerebral artery dissections (<5%)

Epidemiology
• ~10-28/100,000 population/yr
• peak age 55-60, 20% of cases occur under age 45

Risk Factors
• hypertension
• pregnancy/parturition in patients with pre-existing AVMs, eclampsia
• oral contraceptive pill
• substance abuse (cigarette smoking, cocaine, alcohol)
• conditions associated with high incidence of aneurysms (see Intracranial Aneurysms, NS21)

Clinical Features of Spontaneous SAH
• sudden onset (seconds) of severe “thunderclap” headache usually following exertion and described as the “worst headache of my life” (up to 97% sensitive, 12-25% specific)
• nausea/vomiting, photophobia
• meningismus (neck pain/stiffness, positive Kernig’s and Brudzinski’s sign)
• decreased LOC (due to either raised ICP, ischemia, seizure)
• focal deficits: cranial nerve palsies (CN III, IV), hemiparesis
• ocular hemorrhage in 20-40% (due to sudden raised ICP compressing central retinal vein)
• reactive hypertension

Fisher Grade (SAH on CT scan)
Grade | Finding
--- | ---
1 | Normal scan
2 | <1 mm thick blood
3 | >1 mm thick blood
4 | SAH + ICH or IVH

Hunt and Hess Grade (clinical grading scale for SAH)
Grade | Description
--- | ---
1 | No Sx or mild H/A and/or mild meningismus
2 | Grade 1 + CN palsy
3 | Confusion/betargy, mild hemiparesis or aphasia
4 | GCS <15 but >8, moderate-severe hemiparesis, mild rigidity
5 | Coma (GCS <9), decerebrate, moribund appearance

Mortality of Grade 1-2 20%, increased with grade
• sentinel bleeds
  • represents undiagnosed SAH
  • SAH-like symptoms lasting <1 d (“thunderclap H/A”)
  • may have blood on CT or LP
  • ~30-60% of patients with full blown SAH give history suggestive of sentinel bleed within past 3 wk
• differential diagnosis: sentinel bleed, dissection/thrombosis of aneurysm, venous sinus thrombosis, benign cerebral vasculitis, benign exertional H/A

Investigations
• non-contrast CT (Figure 17) – for diagnosis of SAH
  • 98% sensitive within 12 h, 93% within 24 h; 100% specificity
  • may be negative if small bleed or presentation delayed several days
  • acute hydrocephalus, IVH, ICH, infarct or large aneurysm may be visible
• lumbar puncture (highly sensitive) – for diagnosis of SAH if CT negative but high suspicion:
  • bloody initially, xanthochromic supernatant with centrifugation ("yellow") by ~12 h, lasts 2 wk
  • RBC count usually >100,000/mm³ without significant drop from first to last tube (in contrast to traumatic tap)
  • elevated protein due to blood breakdown products
• four vessel cerebral angiography (“gold standard” for aneurysms)
  • demonstrates source of SAH in 80-85% of cases
  • angiogram negative SAH: repeat angiogram in 7-14 d, if negative → “perimesencephalic SAH”
• MRA and CTA: sensitivity up to 95% for aneurysms, CTA>MRA for smaller aneurysms and delineating adjacent bony anatomy

*Intact aneurysm

![Figure 18. Approach to SAH](image)

**Background:** Two rules for SAH diagnosis exist. A clinical prediction rule states that patients with acute severe headache but without the clinical variables age ≥ 40 yr, neck pain, loss of consciousness, or onset of headache with exertion are at low risk for SAH. An imaging prediction rule bases diagnosis on non-contrast cranial CT for patients within 6 h of headache onset.

**Methods:** Matched case-control study of 55 patients at 21 emergency departments between 2000 and 2011, and diagnoses were verified by lumbar puncture.

**Results:** The clinical prediction rule for diagnosis of SAH was 97.1% sensitive, 22.7% specific, and had a negative likelihood ratio of 0.13. Using the imaging prediction rule resulted in a false negative rate of 20%.

**Conclusions:** Performing the clinical and imaging rules together has the potential for maximizing sensitivity of prediction and reducing rates of lumbar puncture, but using imaging alone can result in missed cases.
Treatment
- admit to ICU or NICU
- oxygen/ventilation prn
- NPO, bed rest, elevate head of bed 30°, minimal external stimulation, neurological vitals q1h
- aim to maintain sBP = 120-150 (balance of vasospasm prophylaxis, risk of re-bleed, risk of hypotension since CBF autoregulation impaired by SAH)
- cardiac rhythm monitor, Foley prn, strict monitoring of ins and outs
- medications:
  - IV NS with 20 mmol KCl/L at 125-150 cc/h
  - nimodipine 60 mg PO/NG q4h x 21 d for vasospasm neuroprotection; may discontinue earlier if patient is clinically well
  - seizure prophylaxis: levetiracetam (Keppra®) 500 mg PO/IV q12h x 1 wk
  - mild sedation prn

Complications
- vasospasm: vasoconstriction and permanent pathological vascular changes in response to vessel irritation by blood
  - onset: 4-14 d post-SAH, peak at 6-8 d; most commonly due to SAH, rarely due to ICH/IVH
  - clinical features (delayed ischemic deficit): confusion, decreased LOC, focal deficit (speech or motor)
  - risk factors: large amount of blood on CT (high Fisher grade), smoking, increased age, HTN
  - “symptomatic” vasospasm in 20-30% of SAH patients
  - “radiographic” vasospasm in 30-70% of arteriograms performed 7 d following SAH
  - diagnosed clinically, and/or with transcranial Doppler (increased velocity of blood flow)
  - risk of cerebral infarct and death
- treatment
  - hyperdynamic (“triple H” – see sidebar) therapy using fluids and pressors, usually after ruptured aneurysm has been clipped/coiled
  - direct vasodilation via angioplasty or intraarterial verapamil for refractory cases
  - hydrocephalus (15-20%): due to blood obstructing CSF drainage
  - can be acute or chronic, requires extraventricular drain (EVD) or shunt, respectively
  - neurogenic pulmonary edema
  - hyponatremia: due to cerebral salt wasting (increased renal sodium loss and ECFV loss), not SIADH
  - diabetes insipidus
  - cardiac: arrhythmia (>50% have ECG changes), MI, CHF

Prognosis
- 10-15% mortality before reaching hospital, overall 50% mortality (majority within first 2-3 wk)
- 30% of survivors have moderate to severe disability
- a major cause of mortality is rebleeding, for aneurysms:
  - risk of rebleed: 4% on first day, 15-20% within 2 wk, 50% by 6 mo
  - if no rebleed by 6 mo, risk decreases to same incidence as unruptured aneurysm (2%)
  - only prevention is early clipping or coiling of “cold” aneurysm
  - rebleed risk for “perimesencephalic SAH” is approximately same as for general population

Intracerebral Hemorrhage (ICH)

Definition
- hemorrhage within brain parenchyma, accounts for ~10% of strokes
- can dissect into ventricular system (IVH) or through cortical surface (SAH)

Etiology
- HTN (usually causes bleeds at putamen, thalamus, pons and cerebellum)
- hemorrhagic transformation (reperfusion post stroke, surgery, strenuous exercise, etc.)
- NPO, bed rest, elevate head of bed 30°, minimal external stimulation, neurological vitals q1h
- venous sinus thrombosis
- arteriopathies (cerebral amyloid angiopathy, lipohyalinosis, vasculitis)
- tumors (1%): often malignant (e.g. GBM, lymphoma, metastases)
- drugs (amphetamine, cocaine, alcohol, anticoagulants, etc.)
- coagulopathy (iatrogenic, leukemia, TTP, aplastic anemia)
- CNS infections (fungal, granulomas, herpes simplex encephalitis)
- post trauma (immediate or delayed, frontal and temporal lobes most commonly injured via coup-contrecoup mechanism)
- eclampsia
- post-operative (post-carotid endarterectomy cerebral reperfusion, craniotomy)
- idiopathic
Epidemiology
• 12-15 cases/100,000 population/yr

Risk Factors
• increasing age (mainly >55 yr)
• male gender
• HTN
• Black/Asian > Caucasian
• previous CVA of any type (23x risk)
• both acute and chronic heavy alcohol use; cocaine, amphetamines
• liver disease
• anticoagulants

Clinical Features
• TIA-like symptoms often precede ICH, can localize to site of impending hemorrhage
• location: basal ganglia/internal capsule (50%), thalamus (15%), cerebral white matter (15%), cerebellum/brainstem – usually pons (15%)
• gradual onset of symptoms over minutes-hours, usually during activity
• H/A, N/V, and decreased LOC are common
• specific symptoms/deficits depend on location of ICH

Investigations
• hyperdense blood on non-contrast CT
• CTA routine, if spot sign demonstrated there is high likelihood of clot growth

Treatment
• medical
  ▪ decrease MAP to pre-morbid level or by ~20% (target BP 140/90)
  ▪ check PT/INR, and correct coagulopathy
  ▪ control raised ICP (see Intracranial Pressure Dynamics, NS4)
  ▪ levetiracetam/phenytoin for seizure prophylaxis
  ▪ follow electrolytes (SIADH common)
  ▪ angiogram to r/o vascular lesion unless >45 yr, known HTN, and putamen/thalamic/posterior fossa ICH (yield ~0%)
• surgical
  ▪ craniotomy with evacuation of clot, treatment of source of ICH (i.e. AVM, tumour, cavernoma), ventriculostomy to treat hydrocephalus
  ▪ indications
    ▪ symptoms of raised ICP or mass effect
    ▪ rapid deterioration (especially if signs of brainstem compression)
    ▪ favourable location (e.g. cerebellar, non-dominant hemisphere)
    ▪ young patient (<50 yr)
    ▪ if tumour, AVM, aneurysm, or cavernoma suspected (resection or clip to decrease risk of rebleed)
  ▪ contraindications
    ▪ small bleed: minimal symptoms, GCS >10
    ▪ poor prognosis: massive hemorrhage (especially dominant lobe), low GCS/coma, lost brainstem function
    ▪ medical reasons [e.g. very elderly, severe coagulopathy, difficult location (e.g. basal ganglia, thalamus)]

Prognosis
• 30-d mortality rate 44%, mostly due to cerebral herniation
• rebleed rate 2-6%, higher if HTN poorly controlled

Intracranial Aneurysms

Epidemiology
• prevalence 1-4% (20% have multiple)
• female > male; age 35-65 yr

Risk Factors
• autosomal dominant polycystic kidney disease (15%)
• fibromuscular dysplasia (7-21%)
• AVMs
• connective tissue diseases (Ehlers-Danlos, Marfan)
• family history
• bacterial endocarditis
• Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)
• atherosclerosis and HTN
• trauma
Types (for location, see Figure 4, NS3)
- saccular (berry)
  - most common type
  - located at branch points of major cerebral arteries (Circle of Willis)
  - 85-95% in carotid system, 5-15% in vertebralbasilar circulation
- fusiform
- atherosclerotic
- more common in vertebralbasilar system, rarely rupture
- infectious
  - secondary to any infection of vessel wall, 20% multiple
  - 60% Streptococcus and Staphylococcus
  - 3-15% of patients with bacterial endocarditis

Clinical Presentation
- rupture (90%), most often SAH, but 30% ICH, 20% IVH, 3% subdural bleed
- sentinel hemorrhage ("thunderclap H/A") \rightarrow requires urgent clipping/coiling to prevent catastrophic bleed
- mass effect (giant aneurysms)
  - internal carotid or anterior communicating aneurysm may compress:
    - the pituitary stalk or hypothalamus causing hypopituitarism
    - the optic nerve or chiasm producing a visual field defect
    - basilar artery aneurysm may compress midbrain, pons (limb weakness), or CN III
  - posterior communicating artery aneurysm may produce CN III palsy
  - intracavernous aneurysms (CN III, IV, V1, V2, VI)
  - distal embolization (e.g. amaurosis fugax)
  - seizures
  - headache (without hemorrhage)
  - incidental CT or angiography finding (asymptomatic)

Investigations
- CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

Treatment
- ruptured aneurysms
  - overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
  - treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling), wrapping (last resort)
  - choice of surgery vs. coiling not yet well defined, consider location, size, shape, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition. In general:
    - clipping: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
    - coiling: superficial > deep, broad aneurysmal base, branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hematoma, acute brainstem compression
- unruptured aneurysms
  - average 1% annual risk of rupture: risk dependent on size and location of aneurysm
  - no clear evidence on when to operate: need to weigh life expectancy
  - risk of morbidity/mortality of SAH (20%-50%) vs. surgical risk (2%-5%)
  - generally treat unruptured aneurysms >10 mm
  - consider treating when aneurysm 7-9 mm in middle-aged, younger patients or patients with a family history of aneurysms
  - follow smaller aneurysms with serial angiography

Table 10. 5-year Cumulative Rupture Risk in Unruptured Aneurysms Based on Size and Location

Clinical Presentation
- rupture (90%), most often SAH, but 30% ICH, 20% IVH, 3% subdural bleed
- sentinel hemorrhage ("thunderclap H/A") \rightarrow requires urgent clipping/coiling to prevent catastrophic bleed
- mass effect (giant aneurysms)
  - internal carotid or anterior communicating aneurysm may compress:
    - the pituitary stalk or hypothalamus causing hypopituitarism
    - the optic nerve or chiasm producing a visual field defect
    - basilar artery aneurysm may compress midbrain, pons (limb weakness), or CN III
  - posterior communicating artery aneurysm may produce CN III palsy
  - intracavernous aneurysms (CN III, IV, V1, V2, VI)
  - distal embolization (e.g. amaurosis fugax)
  - seizures
  - headache (without hemorrhage)
  - incidental CT or angiography finding (asymptomatic)

Investigations
- CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

Treatment
- ruptured aneurysms
  - overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
  - treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling), wrapping (last resort)
  - choice of surgery vs. coiling not yet well defined, consider location, size, shape, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition. In general:
    - clipping: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
    - coiling: superficial > deep, broad aneurysmal base, branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hematoma, acute brainstem compression
- unruptured aneurysms
  - average 1% annual risk of rupture: risk dependent on size and location of aneurysm
  - no clear evidence on when to operate: need to weigh life expectancy
  - risk of morbidity/mortality of SAH (20%-50%) vs. surgical risk (2%-5%)
  - generally treat unruptured aneurysms >10 mm
  - consider treating when aneurysm 7-9 mm in middle-aged, younger patients or patients with a family history of aneurysms
  - follow smaller aneurysms with serial angiography

Carotid Stenosis

Definition
- narrowing of the internal carotid artery lumen due to atherosclerotic plaque formation, usually near common carotid bifurcation into internal and external carotids

Risk Factors
- for atherosclerosis: HTN, smoking, DM, CVD or CAD, dyslipidemia

Clinical Features
- may be asymptomatic
- symptomatic stenosis may present as TIA, reversible ischemic neurologic deficit (RIND), or stroke
- retinal insufficiency or infarct permanently or temporarily (amaurosis fugax), (see Ophthalmology, OP37)
- middle cerebral artery (MCA) occlusive symptoms

Investigations
- CBC, PTT/INR (hypercoagulable states)
- fundoscopy: cholesterol emboli in retinal vessels (Hollenhorst plaques)
- auscultation over carotid bifurcation for bruits (do not correlate with degree of stenosis)
- carotid duplex: determines severity of disease (mild/moderate/severe stenosis of occlusion)
- angiogram: “gold standard” but invasive and 1/200 risk of stroke (not for screening)
- MRA: safer than angiogram, may overestimate stenosis

Treatment
- control of HTN, lipids, diabetes
- antiplatelet agents (ASA ± dipyridamole, clopidogrel) ~25% relative risk reduction
- carotid endarterectomy (generally if symptomatic and >70% stenosis, see Tables 11 and 12)
- endovascular angioplasty ± stenting

Prognosis

Vascular Malformations

Types
- arteriovenous malformations (AVMs)
- cavernous malformations (= cavernomas, cavernous hemangiomas/angiomas)
- venous angioma
- capillary telangiectasias
- arterio-venous fistula (AVF) (carotid-cavernous fistula, dural AVF; vein of Galen aneurysm)
- “angiographically occult vascular malformations” (any type, 10% of malformations)

Arteriovenous Malformations (AVMs)

Definition
- tangle of abnormal vessels/arteriovenous shunts, with no intervening capillary beds or brain parenchyma, usually congenital

Epidemiology
- prevalence ~0.14%, male:female = 2:1, average age at diagnosis = 33 yr
- 15-20% of patients with hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome) will have cerebral AVMs

Spetzler-Martin AVM Grading Scale

<td>0</td>
</tr>
<tr>
<td>Present</td>
<td>1</td>
</tr>
</tbody>
</table>

AVM grades calculated by adding the 3 individual Spetzler-Martin Scale scores from the above table. e.g. a 2 cm tumour in noneloquent location without deep venous drainage = Grade I
Clinical Features

- hemorrhage (40-60%): small AVMs are more likely to bleed due to direct high pressure AV connections
- seizures (50%): more common with larger AVMs
- mass effect
- focal neurological signs secondary to ischemia (high flow → "steal phenomena")
- localized headache, increased ICP
- bruit (especially with dural AVMs)
- may be asymptomatic ("silent")

Investigations

- MRI (flow void), MRA
- angiography (7% will also have one or more associated aneurysms)

Treatment

- decreases risk of future hemorrhage and seizure
  - surgical excision is treatment of choice
  - SRS is preferred for small (<3 cm) or very deep lesions
  - endovascular embolization (glue, balloon) can facilitate surgery or SRS for larger lesions
  - conservative (e.g. palliative embolization, seizure control if necessary)

Prognosis

- 10% mortality, 30-50% morbidity (serious neurological deficit) per bleed
- risk of major bleed in untreated AVMs: 2-4% per year

Cavernous Malformations

- benign vascular hamartoma consisting of irregular sinusoidal vascular channels located within the brain without intervening neural tissue or associated large arteries/veins
- several genes now described: CCM1, CCM2, CCM3
- prevalence of 0.1-0.2%, both sporadic and hereditary forms described

Clinical Features

- seizures (60%), progressive neurological deficit (50%), hemorrhage (20%), H/A
- often an incidental finding
- hemorrhage risk less than AVM, usually minor bleeds

Investigations

- T2WI MRI (non-enhancing; see Figure 19) gradient echo sequencing (best for diagnosis)

Treatment

- surgical excision
  - only appropriate for symptomatic lesions that are surgically accessible (supratentorial lesions are less likely to bleed than infratentorial lesions)

EXTRACRANIAL PATHOLOGY

Approach to Limb/Back Pain

- see Orthopedics, OR21

Extradural Lesions

Root Compression

Differential Diagnosis

- herniated disc
- neoplasm (neurofibroma, schwannoma)
- synovial cyst, abscess
- hypertrophic bone/spur

Cervical Disc Syndrome

Etiology

- nucleus pulposus herniates through annulus fibrosus and impinges upon nerve root, most commonly at C6-C7 (C7 root)
Clinical Features
- pain down arm in nerve root distribution, worse with neck extension, ipsilateral rotation and lateral flexion (all compress the ipsilateral neural foramen)
- LMN signs and symptoms
- central cervical disc protrusion causes myelopathy as well as nerve root deficits

Investigations
- if red flags: C-spine x-ray, CT, MRI (imaging of choice)
- only consider EMG, nerve conduction studies if diagnosis uncertain and presenting more as peripheral nerve issue.

Treatment
- conservative
  - no bedrest unless severe radicular symptoms
  - activity modification, patient education (reduce sitting, lifting)
  - physiotherapy, exercise programs focus on strengthening core muscles
  - analgesics, NSAIDs are more efficacious
  - avoid cervical manipulation, like traction
- surgical indications
  - intractable pain despite adequate conservative treatment for >3 mo
  - progressive neurologic deficit
  - anterior cervical discectomy is usual surgical choice

Prognosis
- 95% improve spontaneously in 4-8 wk

Cervical Stenosis (Cervical Spondylosis)

Definition
- cervical spondylosis is chronic disc degeneration and associated facet arthropathy
- resultant syndromes include mechanical neck pain, radiculopathy (root compression), myelopathy (spinal cord compression), and combinations

Epidemiology
- typically begins at age 40-50, male > female, most commonly at the C5-C6 > C6-C7 levels

Pathogenesis
- cervical stenosis leading to spinal cord compression and myelopathy is a serious and common issue
- pathophysiology includes static compression, dynamic compression and vascular compromise

Clinical Features
- insidious onset of mechanical neck pain exacerbated by excess vertebral motion (particularly rotation and lateral bending with a vertical compressive force – Spurling’s test)
- occipital headache is common
- radiculopathy may involve 1 or more roots, and symptoms include neck, shoulder and arm pain, paresthesias and numbness
- cervical myelopathy may be characterized by weakness (upper > lower extremity), decreased dexterity, and sensory changes
- UMN findings such as hyperreflexia, clonus and Babinski reflex may be present
- most worrisome complaint is lower extremity weakness (corticospinal tracts)
- myelopathy may be associated with funicular pain, characterized by burning and stinging ± Lhermitte’s sign (lightning-like sensation down the back with neck flexion)

Investigations
- x-ray of cervical spine ± flexion/extension (alignment, fractures)
- MRI most useful for determination of compression of the neural element
- CT is only used for better determination of bony anatomy (i.e. OPLL)
- EMG/nerve conduction studies reserved for peripheral nerve investigation

Treatment
- decompression and stabilization need to be included in the management
- NSAIDs, moist heat, strengthening and range of motion exercises, analgesics, cervical collar, cervical traction
- surgical indications: myelopathy with motor impairment, progressive neurologic impairment, intractable pain

Disc herniations impinge the nerve root at the level below the interspace (i.e. C5-6 disc affects the C6 nerve root).

Figure 20A. Axial section of cervical spine with vascular and functional territories

Figure 20B. Axial section of thoracic spine with vascular and functional territories

Figure 20C. Axial section of lumbar spine with vascular and functional territories
Lumbar Disc Syndrome

Etiology
• posterolaterally herniated disc compressed nerve root exiting BELOW the level of the disc or the traversing nerve root
• far lateral disc herniation compressed nerve root AT the level of the disc or the exiting nerve root
• central herniation causes cauda equina or lumbar stenosis (neurogenic claudication)

Clinical Features
• initially back pain, then leg pain > back pain
• limited back movement (especially forward flexion) due to pain
• motor weakness, dermatomal sensory changes, decreased reflexes
• exacerbation with coughing, sneezing or straining. Relief with flexing the knee or thigh
• nerve root tension signs
  - straight leg raise (SLR: Lasegue’s test) or crossed SLR (pain should occur at less than 60 degrees) suggests L5, S1 root involvement
  - femoral stretch test suggests L2, L3 or L4 root involvement

Investigations
• MRI is modality of choice
• x-ray spine (only to rule out other lesions), CT (bony anatomy)
• myelogram and post-myelogram CT (only if MRI is contraindicated)

Treatment
• conservative (same as cervical disc disease)
• surgical indications
  - same as cervical disc + cauda equina syndrome

Prognosis
• 95% improve spontaneously within 4 to 8 wk
• do not follow patients with serial MRIs. Clinical status is more important at guiding management

<td>Sphincter dysfunction presents late; impotence less frequent</td>
</tr>
</tbody>
</table>

Cauda Equina Syndrome

Etiology
• compression or irritation of lumbosacral nerve roots below conus medullaris (below L2 level)
• decreased space in the vertebral canal below L2
• common causes: herniated disc ± spinal stenosis, vertebral fracture, and tumour
Clinical Features
- usually acute (develops in less than 24 h); rarely subacute or chronic
- motor (LMN signs)
  - weakness/paraparesis in multiple root distribution
  - reduced deep tendon reflexes (knee or ankle)
- autonomic
  - urinary retention (or overflow incontinence) and/or fecal incontinence due to loss of anal sphincter tone
- sensory
  - low back pain radiating to legs (sciatica) aggravated by Valsalva maneuver and by sitting; relieved by lying down
  - bilateral sensory loss or pain; depends on the level affected
  - saddle area (S2-S5) anesthesia
  - sexual dysfunction (late finding)

Investigations
- urgent MRI to confirm compression of S2-3-4 nerve root by a large disc herniation
- post-void residual very helpful to determine if true retention is present. Volumes controversial but anything over 250 cc in a healthy individual is cause for concerns

Treatment
- surgical decompression (<48 h) to preserve bowel, bladder and sexual function, and/or to prevent progression to paraplegia

Prognosis
- markedly improves with surgical decompression
- recovery correlates with function at initial presentation: if patient is ambulatory, likely to continue to be ambulatory; if unable to walk, unlikely to walk after surgery

Lumbar Spinal Stenosis

Etiology
- congenital narrowing of spinal canal combined with degenerative changes (herniated disc, hypertrophied facet joints, and ligamentum flavum)

Clinical Features
- gradually progressive back and leg pain with standing and walking that is relieved by sitting or lying down (neurogenic claudication – 60% sensitive)
- neurologic exam may be normal, including straight leg raise test

Investigations
- MRI is the optimal investigation to confirm and localize the level of stenosis. Unlike nerve root compression which can be localized with clinical exam this is more difficult and requires imaging

Treatment
- conservative: NSAIDs, analgesia
- surgical: laminectomy with root decompression (the role of fusion may need to be considered if the amount of bone removed with the laminectomy results in de-stabilization)

Neurogenic Claudication

Etiology
- ischemia of lumbosacral nerve roots secondary to vascular compromise and increased demand from exertion, often associated with lumbar stenosis

Clinical Features
- dermatomal pain/paresthesia/weakness of buttock, hip, thigh, or leg initiated by standing or walking
- slow relief with postural changes (sitting >30 min), NOT simply exertion cessation
- induced by variable degrees of exercise or standing
- may be elicited with lumbar extension, but may not have any other neurological findings, no signs of vascular compromise (e.g. ulcers, poor capillary refill, etc.)

Investigations
- bicycle test may help distinguish neurogenic claudication (NC) from vascular claudication (the waist-flexed individuals on the bicycle with NC can last longer)

Treatment
- same as for lumbar spinal stenosis
Intradural Intramedullary Lesions

Syringomyelia (Syrinx)

Definition
- cystic cavitation of the spinal cord
- presentation is highly variable, usually progresses over months to years
- initially pain, weakness; later atrophy and loss of pain and temperature sensation

Etiology
- 70% are associated with Chiari I malformation, 10 % with basilar invagination
- post-traumatic
- tumour
- tethered cord

Clinical Features
- nonspecific features for any intramedullary spinal cord pathology:
  - initially pain, weakness, atrophy, loss of pain and temperature in upper extremities (central syrinx) with progressive myelopathy over years
  - sensory loss with preserved touch and joint position sense in a band-like distribution at the level of cervical syrinx
  - sensory loss: suspended dissociated sensory loss may result in painless ulcerations and/or burns
  - dysesthetic pain often occurs in the distribution of the sensory loss
  - LMN arm/hand weakness or wasting
  - painless neuropathic arthropathies (Charcot’s joints), especially in the shoulder and neck due to loss of pain and temperature sensation (seen in less than 5%)

Investigations
- MRI is best method, myelogram with delayed CT

Treatment
- treat underlying cause (e.g. posterior fossa decompression for Chiari I, surgical removal of tumour if causing a syrinx)
- rarely does the syrinx need to be shunted, only when progressive and size allows for insertion of tube

Spinal Cord Syndromes

- see Neurology, N4, for spinal cord anatomy
- Spinal cord injury impairment classified according to ASIA score
  - ASIA A: complete, no motor/sensory below neurological level including S4/5
  - ASIA B: incomplete, sensory but not motor function preserved below neurological level including S4/5
  - ASIA C: incomplete, motor function preserved below neurological level and more than half of the key muscles below neurological level have a muscle grade <3
  - ASIA D: incomplete, motor function preserved below neurological level and more than half of the key muscles below neurological level have a muscle grade 3 or more
  - ASIA E: normal motor and sensory function

Complete Spinal Cord Lesion
- bilateral loss of motor/sensory and autonomic function at ≥4 segments below lesion/injury, with UMN signs
- about 3% of patients with complete injuries will develop some recovery within 24 h, beyond 24 h, no distal function will recover

Incomplete Spinal Cord Lesion
- any residual function at ≥4 segments below lesion
- signs include sensory/motor function in lower limbs and “sacral sparing” (perianal sensation, voluntary rectal sphincter contraction)
Table 16. Comparison between Incomplete Spinal Cord Lesion Syndromes

Peripheral Nerves

- see Neurology, N31 and Plastic Surgery, PL28

 Seddon's Classification of Peripheral Nerve Injury

- class I: neurapraxia – axon structurally intact but fails to function; recovery within hours to months (average 6-8 wk)
- class II: axonotmesis – axon and myelin sheath disrupted but endoneurium and supporting structures intact → Wallerian degeneration of axon segment distal to injury → spontaneous axonal recovery at 1 mm/d, max at 1-2 yr
- class III: neurotmesis – nerve completely transected, need surgical repair for possibility of recovery
- etiologies: ischemia, nerve entrapment – nerve compressed by nearby anatomic structures, often secondary to localized, repetitive mechanical trauma with additional vascular injury to nerve

Investigations

- neurological exam (power, sensation, reflexes), localization via Tinel’s sign (paresthesias elicited by tapping along the course of a nerve)
- electrophysiological studies (EMG, nerve conduction study) may be helpful in assessing nerve integrity and monitoring recovery, not helpful until 2-3 wk post-injury
- labs: bloodwork, CSF
- imaging: C-spine, chest/bone x-rays, myelogram, CT, magnetic resonance neurography; identify etiology
- angiogram if vascular damage is suspected

Treatment

- early neurosurgical consultation if injury is suspected
- entrapment
  - conservative: prevent repeated stress/injury, physiotherapy, NSAIDs, local anaesthesia/steroid injection
  - surgical: nerve decompression ± transposition for progressive deficits, muscle weakness/atrophy, failure of medical management
- stretch/contusion
  - follow-up clinically for recovery; exploration if no recovery in 3 mo
- axonotmesis
  - if no evidence of recovery, resect damaged segment
  - prompt physical therapy and rehabilitation to increase muscle function, maintain joint range of motion, and maximize return of useful function
  - recovery usually incomplete
- neurotmesis
  - surgical repair of nerve sheath unless known to be intact [suture nerve sheaths directly if ends approximate or nerve graft (usually sural nerve)]
  - clean laceration: early exploration and repair
  - contamination or associated injuries: tag initially with nonabsorbable suture, reapproach within 10 d

Complications

- neuropathic pain: with neuroma formation
- complex regional pain syndrome: with sympathetic nervous system involvement
SPECIALTY TOPICS

Neurotrauma

Trauma Management (see also Emergency Medicine, ER6)

Indications for Intubation in Trauma
1. depressed LOC (patient cannot protect airway): usually GCS ≤8
2. need for hyperventilation
3. severe maxillofacial trauma: patency of airway is doubtful
4. need for pharmacologic paralysis for evaluation or management
   • if basal skull fracture suspected, use orotracheal instead of nasotracheal intubation
   • note: intubation prevents patient’s ability to verbalize for determining GCS

Trauma Assessment

INITIAL MANAGEMENT

ABCs of Trauma Management
• see Emergency Medicine, ER8

NEUROLOGICAL ASSESSMENT

Mini-History
• period of LOC, post-traumatic amnesia, loss of sensation/function, type of injury/accident

Neurological Exam
• Glasgow Coma Scale (GCS)
• head and neck (lacerations, bruises, basal skull fracture signs, facial fractures, foreign bodies)
• spine (palpable deformity, midline pain/tenderness)
• eyes (pupillary size and reactivity)
• brainstem (breathing pattern, CN palsies)
• cranial nerve exam
• motor exam, sensory exam (only if GCS is 15), reflexes
• sphincter tone
• record and repeat neurological exam at regular intervals

Investigations
• spinal injury precautions (cervical collar) are continued until C-spine is cleared
• C, T, L-spine x-rays
  • AP, lateral, odontoid views for C-spine (must see from C1 to T1; swimmer’s view if necessary) or CT
  • rarely done: oblique views looking for pars interarticularis fracture (“Scottie dog” sign)
• CT head and upper C-spine (whole C-spine if patient unconscious) look for fractures, loss of massoid or sinus air spaces, blood in cisterns, pneumocephalus
• cross and type, ABG, CBC, drug screen (especially alcohol)
• chest and pelvic x-ray as indicated

TREATMENT

Treatment for Minor Head Injury
• observation over 24-48 h
• wake every hour
• judicious use of sedatives or pain killers during monitoring period

Treatment for Severe Head Injury (GCS ≤8)
• clear airway and ensure breathing (if GCS ≤8, intubate)
• secure C-spine
• maintain adequate BP
• monitor for clinical deterioration
• monitor and manage increased ICP if present (see Herniation Syndromes, NS7)

Admission required if:
• skull fracture (indirect signs of basal skull fracture, see Head Injury, NS31)
• confusion, impaired consciousness, concussion with >5 min amnesia
• focal neurological signs, extreme headache, vomiting, seizures
• unstable spine
• use of alcohol
• poor social support

• Bone (vertebral bodies, facets, spinous processes)
• Cartilage
• Disc (disc space and interspinous space)
• Soft tissues

The Canadian CT Head Rule for Patients with Minor Head Injury
The Lancet 2001;357:1381-1396

CT Head is only required for patients with minor head injuries with any one of the following:

High risk (for neurological intervention)
• GCS score <15 at 2 h after injury
• Suspected open or depressed skull fracture
• Any sign of basal skull fracture (hemotympanum, “raccoon” eyes, cerebrospinal fluid otorrhea/ rhinorrhea, Battle’s sign)
• Hematoma ≥2 episodes
• Age >65 yr

Medium risk (for brain injury on CT)
• Amnesia after impact >30 min
• Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs)

Minor head injury is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.

• Never do lumbar puncture in head injury unless increased ICP has been ruled out
• All patients with head injury have C-spine injury until proven otherwise
• Suspect hematoma in alcoholic-related injuries
• Low BP after head injury means injury elsewhere
• Must clear spine both radiologically AND clinically
Head Injury

Epidemiology
- male to female: 2-3:1

Pathogenesis
- acceleration/deceleration: contusions, subdural hematoma, axon and vessel shearing/ mesencephalic hematoma
- impact: skull fracture, concussion, epidural hematoma
- penetrating: worse with high velocity and/or high missile mass
  - low velocity: highest damage to structures on entry/exit path
  - high velocity: highest damage away from missile tract

Scalp Injury
- rich blood supply
- considerable blood loss (vessels contract poorly when ruptured)
- minimal risk of infection due to rich vascularity

Skull Fractures
- depressed fractures: double density on skull x-ray (outer table of depressed segment below inner table of skull), CT with bone window is gold standard
- simple fractures (closed injury): no need for antibiotics, no surgery
- compound fractures (open injury): increased risk of infection, surgical debridement within 24 h is necessary
- internal fractures into sinus may lead to meningitis, pneumocephalus
- risk of operative bleed may limit treatment to antibiotics
- basal skull fractures: not readily seen on x-ray, rely on clinical signs
  - retroauricular ecchymoses (Battle's sign)
  - periorbital ecchymoses (raccoon eyes)
  - hemotympanum
  - CSF rhinorrhea, otorrhea (suspect CSF if halo or target sign present); suspect with Lefort II/III midface fracture

Cranial Nerve Injury
- most traumatic causes of cranial nerve injury do not warrant surgical intervention
- surgical intervention
  - CN II: local eye/orbit injury
  - CN III, IV, VI: if herniation secondary to mass
  - CN VII: repair of ossicles
- CN injuries that improve
  - CN I: recovery may occur in a few months; most do not improve
  - CN III, IV, VI: majority recover
  - CN VII: recovery with delayed lesions
- CN VIII: vestibular symptoms improve over weeks, deafness usually permanent (except when resulting from hemotympanum)

Arterial Injury
- e.g. carotid-cavernous (C-C) fistula, carotid/vertebral artery dissection

Intracranial Bleeding
- see Blood, NS16 and Cerebrovascular Disease, NS18

Brain Injury

Primary Impact Injury
- mechanism of injury determines pathology: penetrating injuries, direct impact
  - low velocity: local damage
  - high velocity: distant damage possible (due to wave of compression), concussion
- concussion: a trauma-induced alteration in mental status
  - American Academy of Neurology (AAN) Classification (see sidebar)
  - no parenchymal abnormalities on CT
- coup (damage at site of blow) and contrecoup (damage at opposite site of blow) (see Figure 25)
  - acute decompression causes cavitation followed by a wave of acute compression
- contusion (hemorrhagic)
  - high density areas on CT ± mass effect
  - commonly occurs with brain impact on bony prominences (inferior frontal lobe, pole of temporal lobe)
- diffuse axonal injury/shearing
  - wide variety of damage results
  - may tear blood vessels (hemorrhagic foci)
  - often the cause of decreased LOC if no space occupying lesion on CT

A Trial of Intracranial-Pressure Monitoring in Traumatic Brain Injury
NEJM 2012;367:2471-2481
Background: ICP monitoring is frequently used to monitor severe traumatic brain injury, but controversy exists over whether it is beneficial.
Methods: Study sample (n=324 patients, aged 13 yr or older) consisted of those who had severe traumatic brain injury and were being treated in ICU in Bolivia or Ecuador. Patients were randomly assigned to one management group:
1. ICP-monitoring based management or
2. management based on imaging and clinical examination.
Results: No significant difference between management groups based on primary outcome, 6-mo mortality, median length of ICU stay, or occurrence of serious adverse events. However, duration of brain-specific treatments (e.g., use of hyperosmolar fluids or hyperventilation) higher in the imaging-clinical examination group (4.8 d vs. 3.4 d, p=0.002).
Conclusion: Maintaining monitored ICP at 20 mmHg or less is not superior to care based on imaging and clinical examination.

AAN Classification
Grade 1: altered mental status < 15 min
Grade 2: altered mental status > 15 min
Grade 3: any loss of consciousness
See sidebar on NS32 for management by classification
Secondary Pathologic Processes
- same subsequent biochemical pathways for each traumatic etiology
- delayed and progressive injury to the brain due to
  - high glutamate release \(\rightarrow\) NMDA \(\rightarrow\) cytotoxic cascade
  - cerebral edema
  - intracranial hemorrhages
  - ischemia/infarction
  - raised ICP, intracranial HTN
  - hydrocephalus

Extracranial Conditions
- hypoxemia
  - due to trauma to the chest, upper airway, brainstem
  - extremely damaging to vulnerable brain cells
  - leads to ischemia, raised ICP
- hypercarbia
  - leads to raised ICP (secondary to vasodilation)
- systemic hypotension
  - caused by blood loss (e.g., ruptured spleen)
  - loss of cerebral autoregulation leads to decreased CPP, ischemia
- hyperpyrexia
  - leads to increased brain metabolic demands \(\rightarrow\) ischemia
- fluid and electrolyte imbalance
  - iatrogenic (most common)
  - SIADH caused by head injury
  - diabetes insipidus (DI)
  - may lead to cerebral edema and raised ICP
- coagulopathy

Intracranial Conditions
- raised ICP due to traumatic cerebral edema OR traumatic intracranial hemorrhage

Brain Injury Outcomes
- mildly traumatic (GCS 13–15): post-concussive symptoms: H/A, fatigue, dizziness nausea, blurred vision, diplopia, memory impairment, tinnitus, irritability, low concentration; 50% at 6 wk, 14% at 1 yr
- moderately traumatic (GCS 9–12): proportional to age (>40) and CT findings; 60% good recovery, 26% moderately disabled, 7% severely disabled, 7% vegetative/dead
- severe (GCS ≤8): difficult to predict, correlates with post-resuscitation GCS (especially motor) and age

Late Complications of Head/Brain Injury
- seizures: 5% of head injury patients develop seizures
  - incidence related to severity and location of injury (increased with local brain damage or intracranial hemorrhage)
  - post-traumatic seizure may be immediate, early, or late
  - presence of early (within first wk) post-traumatic seizure raises incidence of late seizures
- menigitis: associated with CSF leak from nose or ear
- hydrocephalus: acute hydrocephalus or delayed normal pressure hydrocephalus (NPH)

Spinal Cord Injury (SCI)
- see Orthopedics, OR21 and Emergency Medicine, ER9

Neurogenic and Spinal Shock
1. neurogenic shock: hypotension that follows SCI (sBP usually ≤80 mmHg) caused by:
   - interruption of sympathectics (unopposed parasympathetics) below the level of injury
   - loss of muscle tone due to skeletal muscle paralysis below level of injury \(\rightarrow\) venous pooling
   - relative hypovolemia
   - blood loss from associated wounds (true hypovolemia)
2. spinal shock: transient loss of all neurologic function below the level of the spinal cord injury, causing flaccid paralysis and areflexia for variable periods

Whiplash-Associated Disorders
- definition: traumatic injury to the soft tissue structures in the region of the cervical spine due to hyperflexion, hyperextension, or rotational injury to the neck
Initial Management of SCI
• major causes of death in SCI are aspiration and shock
• the following patients should be treated as having a SCI until proven otherwise:
  ▪ all victims of significant trauma
  ▪ minor trauma patients with decreased LOC or complaints of neck or back pain, weakness, abdominal breathing, numbness/tingling, or priapism

Stabilization and Initial Evaluation in the Hospital
1. ABCs, immobilization (backboard/head strap), oxygenation, foley catheter to urometer, temperature regulation
2. hypotension: maintain sBP >90 mmHg with pressors (dopamine), hydration, and atropine
   ▪ DVT prophylaxis
3. monitor CBC/electrolytes
4. focused history (see Trauma Assessment, NS30)
5. spine palpation: point tenderness or deformity
6. motor level assessment (including rectal exam for voluntary anal sphincter contraction)
7. sensory level assessment: pinprick, light touch, and proprioception
8. evaluation of reflexes
9. signs of autonomic dysfunction: altered level of perspiration, bowel or bladder incontinence, priapism
10. radiographic evaluation
   ▪ 3 views C-spine x-rays (AP, lateral, and odontoid) to adequately visualize C1 to C7-T1 junction
   ▪ flexion-extension views to disclose occult instability
   ▪ CT scan (bony injuries) typically most trauma centre use the CT as the modality of choice for looking at fractures, very sensitive with the high resolution scanners.
   ▪ MRI mandatory if neurological deficits (soft tissue injuries)

Medical Management Specific to SCI
• option: methylprednisolone (given within 8 h of injury) this is controversial and you need to confer with Neurosurgery service
• ± decompression in acute, non-penetrating SCI

Fractures of the Spine
FRAC TURES AND FR AC TURE-DISLOCATIONS OF THE TH ORACIC AND LUMBAR SPINE
• assess ligamentous instability using flexion/extension x-ray views of C-spine ± MRI
• thoracolumbar spine unstable if 4/6 segments disrupted (3 columns divided into left and right)
  ▪ anterior column: anterior half of vertebral body, disc, and anterior longitudinal ligament
  ▪ middle column: posterior half of vertebral body, disc, and posterior longitudinal ligament
  ▪ posterior column: posterior arch, facet joints, pedicle, lamina and supraspinous, interspinous and ligamentum ligaments

Types of Injury (Denis Classification)
• compression fracture (58%)
  ▪ produced by flexion
  ▪ posterior ligament complex (supraspinous and interspinous ligaments, ligamentum flavum and intervertebral joint capsules) remain intact
  ▪ fractures are stable but lead to kyphotic deformity
• burst fracture (17%)
  ▪ stable: anterior and middle columns parted with bone retropulsed nearby
    ▪ hallmark is pedicle widening on AP X-ray
    ▪ spinal cord (seen on x-ray and CT); posterior column is uninjured
  ▪ unstable: same as the stable but with posterior column disruption (usually ligamentous)
• flexion distraction injury (6%)
  ▪ hyperflexion and distraction of posterior elements
  ▪ middle and posterior columns fail in distraction
  ▪ classic: Chance = horizontal fracture through posterior arch, pedicles, posterior vertebral body
  ▪ can be purely ligamentous, i.e. through PLL and disc
• fracture-dislocation (6%)
  ▪ anterior and cranial dislocation of superior vertebral body ➔ 3 column failure
  ▪ three types:
    ▪ flexion-rotation
    ▪ flexion-distraction
    ▪ shear/hyperextension (rare)

Management of Thoracolumbar Injury
• severity and management based on TLICS classification (see sidebar)
FRACTURES OF THE CERVICAL SPINE

Types of Injury
- C1 vertebral fracture (Jefferson fracture)
  - vertical compression forces the occipital condyles of the skull down on the C1 vertebra (atlas), pushing the lateral masses of the atlas outward and disrupting the ring of the atlas
  - also can cause an occipital condylar fracture
- odontoid process fracture (see Figure 26)
  - causes C1 and odontoid of C2 to move independently of C2 body
  - this occurs because
    - normally C1 vertebra and odontoid of C2 are a single functional unit
    - alar and transverse ligaments on posterior aspect of odontoid most commonly remain intact following injury
  - patients often report a feeling of instability and present holding their head with their hands
- C2 vertebral fracture (hangman fracture, traumatic spondylolisthesis of axis):
  - bilateral fracture through the pars interarticularis of C2 with subluxation of C2 on C3
  - usually neurologically intact
- Clay-Shoveler fracture
  - avulsion of spinous process, usually C6 or C7

Imaging
- AP spine x-ray (open-mouth and lateral view), CT

Treatment
- immobilization in cervical collar or halo vest until healing occurs (usually 2-3 mo)
- Type II and III odontoid fractures
  - consider surgical fixation for comminution, displacement or inability to maintain alignment with external immobilization
  - confirm stability after recovery with flexion-extension x-rays

Neurologically Determined Death

Definition
- irreversible and diffuse brain injury resulting in absence of clinical brain function
- cardiovascular activity may persist for up to 2 wk

Criteria of Diagnosis
- prerequisites: no CNS depressant drugs/neuromuscular blocking agents, no drug intoxication/poisoning, temperature >32°C, no electrolyte/acid-base/endocrine disturbance
- absent brainstem reflexes:
  - absent pupillary light reflex
  - absent corneal reflexes
  - absent oculocephalic response
  - absent caloric responses (e.g. no deviation of eyes to irrigation of each ear with 50 cc of ice water – allow 1 min after injection, 5 min between sides)
  - absent pharyngeal and tracheal reflexes
  - absent cough with tracheal suctioning
  - absent respiratory drive at PaCO2 >60 mmHg or >20 mmHg above baseline (apnea test)
- 2 evaluations separated by time, usually performed by two specialists (e.g. anesthetist, neurologist, neurosurgeon)
- confirmatory testing: flat EEG, absent perfusion assessed with cerebral angiogram

Coma

Definition
- an unrousable state in which patients show no meaningful response to environmental stimuli

Pathophysiology
- lesions affecting the cerebral cortex bilaterally, the reticular activating system (RAS) or their connecting fibres
- focal supratentorial lesions do not alter consciousness except by herniation (compression on the brainstem or on the contralateral hemisphere) or by precipitating seizures
Classification
- structural lesions (tumour, pus, blood, infarction, CSF): 1/3 of comas
  - supratentorial mass lesion: leads to herniation
  - infratentorial lesion: compression of or direct damage to the RAS or its projections
- metabolic disorders/diffuse hemispheric damage: 2/3 of comas
  - deficiency of essential substrates (e.g. oxygen, glucose, vitamin B₁₂)
  - exogenous toxins (e.g. drugs, heavy metals, solvents)
  - endogenous toxins/systemic metabolic diseases (e.g. uremia, hepatic encephalopathy, electrolyte imbalances, thyroid storm)
  - infections (meningitis, encephalitis)
  - trauma (concussion, diffuse shear axonal damage)

Investigations and Management
- ABCs
- labs: electrolytes, extended electrolytes, TSH, LFTs, Cr, BUN, toxin screen, glucose
- CT/MRI, LP, EEG

**Persistent Vegetative State**

Definition
- a condition of complete unawareness of the self and the environment accompanied by sleep-wake cycles with either complete or partial preservation of hypothalamic and brainstem autonomic function
- “awake but not aware”
- follows comatose state

Etiology/Prognosis
- most commonly caused by cardiac arrest or head injury
- due to irreversible loss of cerebral cortical function but intact brainstem function
- average life expectancy is 2-5 yr

**Pediatric Neurosurgery**

**Spinal Dysraphism**

**SPINA BIFIDA OCCULTA**

Definition
- congenital absence of a spinous process and a variable amount of lamina
- no visible exposure of meninges or neural tissue

Epidemiology
- 15-20% of the general population; most common at L5 or S1

Etiology
- failure of fusion of the posterior neural arch

Clinical Features
- no obvious clinical signs
- presence of lumbosacral cutaneous abnormalities (dimple, sinus, port-wine stain, or hair tuft) should increase suspicion of an underlying anomaly (lipoma, dermoid, diastematomyelia)

Investigations
- plain film: absence of the spinous process along with minor amounts of the neural arch
- U/S, MRI to exclude spinal anomalies

Treatment
- requires no treatment

Figure 27. Spina bifida occulta
MENINGOCELE (SPINA BIFIDA APERTA)

Definition
• herniation of meningeal tissue and CSF through a defect in the spine, without associated herniation of neural tissue

Etiology
• primary failure of neural tube closure

Clinical Features
• most common in lumbosacral area
• usually no disability, low incidence of associated anomalies and hydrocephalus

Investigations
• plain films, CT, MRI, U/S, echo, genitourinary (GU) investigations

Treatment
• surgical excision and tissue repair (excellent results)

MYELOMENINGOCELE (SPINA BIFIDA APERTA)

Definition
• herniation of meningeal and CNS tissue through a defect in the spine

Etiology
• same as meningocele

Clinical Features
• sensory and motor changes distal to anatomic level producing varying degrees of weakness
• urinary and fecal incontinence
• 65-85% of patients with myelomeningocele have hydrocephalus
• most have Type II Chiari malformation (see Chiari Malformations, NS37)

Investigations
• plain films, CT, MRI, U/S, echo, GU investigations

Treatment
• surgical closure to preserve neurologic status and prevent CNS infections
• closure in-utero shown to decrease hydrocephalus and improve post natal motor scores

Prognosis
• operative mortality close to 0%, 95% 2-yr survival
• 80% have IQ >80 (but most are 80-95), 40-85% ambulatory, 3-10% have normal urinary continence
• early mortality usually due to Chiari malformation complications (respiratory arrest and aspiration), whereas late mortality is due to shunt malfunction

Intraventricular Hemorrhage (IVH)

• see Pediatrics, P73

Hydrocephalus in Pediatrics

Etiology
• congenital
  • aqueductal anomalies, primary aqueductal stenosis in infancy
  • secondary gliosis due to intrauterine viral infections (mumps, varicella, TORCH)
  • Dandy-Walker malformation (2-4%)
  • Chiari malformation, especially Type II
  • myelomeningocele
• acquired
  • post meningitis
  • post hemorrhage (SAH, IVH)
  • masses (vascular malformation, neoplastic)

Clinical Features
• symptoms and signs of hydrocephalus are age related in pediatrics
• increased head circumference (HC), bulging anterior fontanelle, widened cranial sutures
• irritability, lethargy, poor feeding and vomiting
• “cracked pot” sound on cranial percussion
• scalp vein dilation (increased collateral venous drainage)
• sunset sign – forced downward deviation of eyes
• episodic bradycardia and apnea

Investigations
• skull x-ray, U/S, CT, MRI, ICP monitoring

Treatment
• similar to adults (see Hydrocephalus, NS8)

Dandy-Walker Malformation

Definition
• atresia of foramina of Magendie and Luschka, resulting in:
  • complete or incomplete agenesis of the cerebellar vermis with widely separated, hypoplastic
cerebellar hemispheres
  • posterior fossa cyst, enlarged posterior fossa
  • dilatation of 4th ventricle (also 3rd and lateral ventricles)
• associated anomalies
  • hydrocephalus (90%)
  • agenesis of corpus callosum (17%)
  • occipital encephalocele (7%)

Epidemiology
• 2-4% of pediatric hydrocephalus

Clinical Features
• 20% are asymptomatic, seizures occur in 15%
• symptoms and signs of hydrocephalus combined with a prominent occiput in infancy
• ataxia, spasticity, poor fine motor control common in childhood

Investigations
• ultrasound, CT, MRI

Treatment
• asymptomatic patients require no treatment
• associated hydrocephalus requires surgical treatment
  • e.g. ventriculoperitoneal (VP) shunt, cystoperitoneal (CP) shunt, limboperitonal (LP) shunt,
ventriculoatrial (VA) shunt, lumbar drain

Prognosis
• 75-100% survival, 50% have normal IQ

Chiari Malformations

Definition
• malformations at the medullary-spinal junction

Etiology
• unclear, likely maldevelopment/dysgenesis during fetal life

Categories
• Type I (cerebellar ectopia)
  • definition: cerebellar tonsils lie below the level of the foramen magnum
  • epidemiology: average age at presentation 15 yr
  • clinical features:
    • many are asymptomatic
    • scoliosis
    • brain compression
    • central cord syndrome (65%)
    • syringomyelia (50%)
    • foramen magnum compression syndrome (22%)
    • cerebellar syndrome (11%)
    • hydrocephalus (10%)
• Type II
  • definition: part of cerebellar vermis, medulla, and 4th ventricle extend through the foramen
magnum often to midcervical region
  • almost always associated with a myelomingocele
  • epidemiology: present in infancy
  • clinical features: findings due to brainstem and lower cranial nerve dysfunction
  • syringomyelia, hydrocephalus in >80%
Investigations
- MRI

Treatment
- indications for surgical decompression
  - Type I: symptomatic patients (early surgery recommended; <2 yr post symptom onset) → suboccipital craniectomy, duraplasty
  - Type II: neurogenic dysphagia, stridor, apneic spells → cervical laminectomy, duraplasty

Craniosynostosis

Definition
- premature closure of the cranial suture(s)

Classification
- sagittal (most common): long narrow head with ridging sagittal suture (scaphocephaly)
- coronal: expansion in superior and lateral direction (brachiocephaly)
- metopic (trigonocephaly)
- lambdoid: least common

Epidemiology
- 0.6/1000 live births, most cases are sporadic; familial incidence is 2% of sagittal and 8% of coronal synostosis

Clinical Features
- skull deformity, raised ICP ± hydrocephalus
- ophthalmologic problems due to increased ICP or bony abnormalities of the orbit
- must differentiate between positional plagiocephaly (secondary to back sleeping)

Investigations
- plain radiographs, CT scan

Treatment
- parental counseling about nature of deformity, associated neurological symptoms
- surgery for cosmetic purposes, except in cases of elevated ICP (≥2 sutures involved)

Pediatric Brain Tumours

- see also Tumours, NS10

Epidemiology
- 20% of all pediatric cancers (second only to leukemia)
- 60% of pediatric brain tumours are infratentorial
- pediatric brain tumours arise from various cellular lineages
  - glia: low-grade astrocytoma (supra- or infratentorial), anaplastic astrocytoma, glioblastoma multiforme (largely supratentorial) (see Astrocytoma, NS13 for details)
  - primitive nerve cells: supratentorial [primitive neuroectodermal tumour (PNET)]
  - 90% of neonatal brain tumours, infratentorial (medulloblastoma), pineal gland (pineoblastoma)
  - non-neuronal cells: germ cell tumour, craniopharyngioma, dermoid, meningioma, neurinoma (schwanoma), pituitary adenoma, others

Clinical Features
- vomiting, seizure, macrocrania, hydrocephalus
- developmental delay, poor feeding, failure to thrive
- often initially escapes diagnosis due to expansile cranium and neural plasticity in children

### Surgical Management of Epilepsy

- see Neurology, N16 for the medical treatment of epilepsy

**Indications**
- medically refractory seizures, usually defined as seizures resistant to two first line anti-seizure medications used in succession
- identification of a distinct epileptogenic region through clinical history, EEG, MRI, and neuropsychological testing. Other localizing investigations include magnetoencephalography, SPECT, and PET
- if a distinct epileptogenic region cannot be identified, the patient may be a candidate for a palliative procedure such as corpus callosotomy

**Procedure**
- adults: resection of the hippocampus and parahippocampal gyrus for mesial temporal lobe epilepsy arising from mesial temporal sclerosis
- children: resection of an epileptogenic space-occupying lesion
- hemispherectomy and corpus callosotomy are less common

**Outcomes**
- 41-79% of adult patients are seizure free for 5 yr after temporal lobe resection
- 58-78% of children are seizure free after surgery
- surgery is associated with improvements in preexisting psychiatric conditions such as depression and anxiety, as well as improvement in quality of life measures

**Morbidity**
- 0.4-4% of surgical patients will have partial hemianopsia, aphasia, motor deficit, sensory deficit, or cranial nerve palsy following anteromedial temporal lobectomies
- most patients will have some decline in verbal memory following dominant temporal lobectomy and in visuospatial memory in non-dominant temporal resection
- the degree of memory decline stabilizes after 1-2 yr

**Predictors**
- positive predictive factors for seizure freedom following anteromedial temporal lobectomy
  - hippocampal sclerosis (unilateral)
  - focal localization of interictal epileptiform discharges
  - absence of preoperative generalized seizures
  - tumoural cause
  - complete resection of the lesion

---

**A Randomized, Controlled Trial of Surgery for Temporal Lobe Epilepsy**

*NEJM* 2001;345:311-318

**Introduction**: This RCT evaluates the efficacy and safety of neurosurgery for temporal lobe epilepsy. Methods: 80 patients with poorly controlled temporal lobe epilepsy were randomized for surgery (n=40) or for continued treatment with antiepileptic drugs (n=40). The primary outcome was freedom from seizures that impair awareness of self and surroundings during the period of 1 yr. Secondary outcomes included frequency and severity of seizures, quality of life, disability and death.

**Results**: The surgical group had higher cumulative proportion of patients without seizures impairing awareness compared to the medical group (p<0.01). The surgical group also had lower seizure frequency (p<0.001) and better quality of life (p<0.001). 4 patients in the surgical group had adverse effects (thalamic infarct, n = 1; wound infection, n = 1; verbal memory decline impairment occupation, n = 2). One patient in the medical group died; no patients died in the surgical group.

**Conclusions**: In patients with poorly controlled temporal-lobe epilepsy, surgery is superior to prolonged medical therapy.
Surgical Management for Trigeminal Neuralgia

- reserved for cases refractory to medical management; see Neurology, N36 for medical management

Surgical Options
- trigeminal nerve branch procedures
  - local blocks (phenol, alcohol)
  - neurectomy of the trigeminal branch
- nerve branches
  - V1: block at the supraorbital, supratrochlear nerves
  - V2: block at the foramen rotundum or infraorbital nerves
  - V3: block at the foramen ovale
- percutaneous trigeminal rhizotomy
  - glycerol injection
  - mechanotrauma via catheter balloon
- radiofrequency thermocoagulation
- Gamma Knife® radiosurgery
- microvascular decompression
  - posterior fossa craniotomy with microsurgical exploration of the root entry zone, displacement of the vessel impinging on the nerve with placement of non-absorbable Teflon® felt

Common Medications

Table 21. Common Medications

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Dosing Schedule</th>

<th>Side Effects</th>
<th>Common Interactions</th>
<th>Contraindications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>lorazepam</td>
<td>4 mg IV over 2 min, q10-15min (do not exceed 8 mg/12h)</td>
<td>Status epilepticus</td>
<td>Drowsiness, sedation</td>
<td>Other CNS depressants, digoxin (increases digoxin levels)</td>
<td>Start phenytoin loading simultaneously</td>
<td></td>
</tr>
<tr>
<td>carbamazepine</td>
<td>Trigeminal neuralgia (tic douloureux): 100 mg PO bid, increase by 200 mg/d up to a maximum of 1200 mg/d Seizures: 200 mg PO bid, increase by 200 mg (inpatient: q3hd; outpatient: q7d) until therapeutic level achieved (usual optimum dosage: 800-1200 mg/d; range: 600-2000 mg/d)</td>
<td>Seizures</td>
<td>Worsening of seizures, heart failure, arrhythmias, AV block, aplastic anemia, agranulocytosis, thrombocytopenia, hepatitis, erythema multiforme, Stevens-Johnson syndrome</td>
<td>Lithium (increases lithium toxicity), MAOI Other meds may increase carbamazepine levels or have decreased effects</td>
<td>Hypersensitivity to TCAs, previous bone marrow suppression, MAOI in past 14 d Monitor CBC (potential hematological toxicity)</td>
<td></td>
</tr>
<tr>
<td>phenytoin</td>
<td>Seizures: Loading dose: 18 mg/kg slow IV or 300-600 mg PO/d divided bid/tid Maintenance: 200-500 mg IV/d (max rate: &lt;40-50 mg/min or 300 mg PO q4h); average maintenance dose: 300 mg/d PO Status epilepticus: 200 mg IV over 30 min (~ 20 mg/kg; if not taking regularly), or 500 mg IV over 10 min (if already on phenytoin)</td>
<td>Seizures Status epilepticus</td>
<td>Thrombocytopenia, leukopenia, agranulocytosis, pancytopenia, toxic hepatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis</td>
<td>Other meds may increase phenytoin levels and toxicity or have decreased effects</td>
<td>Bradyarrhythmias, heart block Important to give over time to prevent causing a cardiac arrest</td>
<td></td>
</tr>
<tr>
<td>dexamethasone</td>
<td>Loading dose: 10-20 mg IV Maintenance: 4-6 mg IV/d divided qid (may be PO)</td>
<td>Cerebral edema (e.g. secondary to tumour, head injury, pseudotumour cerebri) Preoperative preparation for patients with increased ICP secondary to brain neoplasms</td>
<td>Pseudotumour cerebri, seizures, heart failure, arrhythmias, thromboembolism, pancreatitis, acute adrenal insufficiency; avoid abrupt withdrawal</td>
<td>Aminoglutethimide, anti-diabetics, ASA, NSAIDs, barbituates, phenytoin, rifampin, cardiac glycosides, cyclosporine, ephedrine, oral anticoagulants, potassium-depleting drugs, salicylates, skin-testing antigens, toxoids, vaccines</td>
<td>Systemic fungal infections, immunosuppressive dose with live virus vaccines No longer used in acute spinal cord injury</td>
<td></td>
</tr>

**Basic Anatomy Review**

**Fetal Circulation**
- Umbilical arteries (deoxygenated blood)
- Umbilical vein (oxygenated blood)
- Endometrial artery
- Endometrial vein
- Amnion
- Chorion (fetal)
- Decidua (maternal)
- Placenta
- Umbilical cord

**Maternal Circulation**
- Endometrial artery
- Endometrial vein

Figure 1. Placental blood flow

**Placenta**
- Site of fetal nutritive, respiratory, and excretory function
- Discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by fissures into cotyledons (lobules) on the uterine side
- Produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β-hCG and IGFs
- Poor implantation can lead to spontaneous abortion
- Abnormal location, implantation, or detachment can lead to antepartum hemorrhage
- (see Antepartum Hemorrhage, OB25)

**Pregnancy**

**Diagnosis of Pregnancy**

**History**
- Obstetrical and gynecological history
- Obtain the year, location, mode of delivery, duration of labour, sex, gestational age, birth weight and complications of every pregnancy; organize into GTPAL format:
  - Gravity (G)
    - G: total number of pregnancies of any gestation
    - Includes current pregnancy, abortions, ectopic pregnancies, and hydatidiform moles (multiple gestation = one pregnancy)
  - Parity (TPAL)
    - T: number of term infants delivered (>37 wk)
    - P: number of premature infants delivered (20-36+6 wk)
    - A: number of abortions (loss of intrauterine pregnancy prior to viability of fetus <20 wk and/or <500 g fetal weight)
      - Induced (therapeutic) and spontaneous (miscarriage)
    - L: number of living children
  - Symptoms: amenorrhea, nausea and/or vomiting, breast tenderness, urinary frequency, fatigue

**Physical Signs**
- Goodell's sign: softening of the cervix (4-6 wk)
- Chadwick's sign: bluish discolouration of the cervix and vagina due to pelvic vasculature engorgement (6 wk)
- Hegar's sign: softening of the cervical isthmus (6-8 wk)
- Uterine enlargement
- Breast engorgement

**Acronyms**

- ACOG: American Congress of Obstetricians and Gynecologists
- AFI: amniotic fluid index
- AEFP: acute fatty liver of pregnancy
- AFV: amniotic fluid volume
- ALPHA: antenatal psychosocial health assessment
- AP: anteposterior
- APS: antiphospholipid antibody syndrome
- BPP: biophysical profile
- C/S: Cesarean section
- CD: cervical dilation and curettage
- DIC: disseminated intravascular coagulation
- DVT: deep vein thrombosis
- D lying: external cephalic version
- EFM: electronic fetal monitoring
- EFW: estimated fetal weight
- FDP: fibrin degradation products
- FHR: fetal heart rate
- FL: femur length
- FM: fetal movement
- FPG: fasting plasma glucose
- FTS: first trimester screen
- GACOG: Group B Streptococcus
- GDM: gestational diabetes mellitus
- HC: head circumference
- HELLP: hemolysis, elevated liver enzymes, low platelets
- IGf: infant growth factors
- ILO: induction of labour
- IP: integrated prenatal screen
- IUFD: intrauterine fetal death
- IUGR: intrauterine growth restriction
- IVH: intraventricular hemorrhage
- LDP: left lateral decubitus position
- LMP: last menstrual period
- MSAFP: maternal serum α-fetoprotein
- MSX: maternal serum screen
- MTX: methotrexate
- NST: non-stress test
- NTd: neural tube defects
- NTUS: nuchal translucency ultrasound
- OA: occiput anterior
- OCCT: oral glucose challenge test
- ONTD: open neural tube defect
- OP: occiput posterior
- OT: occiput transverse
- PAPP-a: pregnancy-associated plasma protein A plasma glucose
- PPD: postpartum depression
- PPH: postpartum hemorrhage
- PROM: preterm premature rupture of membranes
- PROM: premature rupture of membranes
- PTL: preterm labour
- RDS: respiratory distress syndrome
- ROM: rupture of membranes
- SHF: symphysis fundal height
- SOCQ: Society ofObstetricians and Gynaecologists of Canada
- SUV: spontaneous vaginal delivery
- TENS: transcutaneous electrical neuro stimulation
- TPN: total parental nutrition
- UTI: urinary tract infection
- VBAC: vaginal birth after Cesarean

**Umbilical Vessels**
- Always check the umbilical cord for 2 arteries and 1 vein: approximately 1/3 of babies with a single uterine artery will have another anomaly.
Investigations

- **β-hCG**: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy
  - positive in serum 9 d post-conception, positive in urine 28 d after first day of LMP
  - plasma levels double every 1-2 d, peak at 8-10 wk, then fall to a plateau until delivery
  - levels less than expected by dates suggest: ectopic pregnancy, abortion, or inaccurate dates
  - levels higher than expected suggest: multiple gestation, molar pregnancy, trisomy 21, or inaccurate dates

- **U/S**
  - transvaginal
    - 5 wk: gestational sac visible (β-hCG ≥1,200-1,500 mIU/mL)
    - 6 wk: fetal pole seen
    - 7-8 wk: fetal heart tones visible
  - transabdominal
    - 6-8 wk: intratube pregnancy visible (β-hCG ≥6,500 mIU/mL)

Maternal Physiology

Table 1. Physiologic Changes During Pregnancy

<table>
<thead>
<tr>
<th>Skin</th>
<th>Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation) Other: spider angiomas, palmar erythema due to increased estrogen, striae gravidarum due to connective tissue changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cardiovascular</td>
<td>Hyperdynamic circulation Increased CO, HR and blood volume Decreased BP due to decreased PVR Enlarging uterus compresses IVC and pelvic veins Decreased venous return leads to risk of hypotension Increased venous pressure leads to risk of varicose veins, hemorrhoids, leg edema</td>
</tr>
<tr>
<td>Hematologic</td>
<td>Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit Increased leukocyte count but impaired function leads to improvement in autoimmune diseases Gestational thrombocytopenia: mild (platelets &gt;70,000/µL) and asymptomatic, normalizes within 2-12 wk following delivery Hypercoagulable state: increased risk of DVT and PE but also decreased bleeding at delivery</td>
</tr>
<tr>
<td>Respiratory</td>
<td>Increased incidence of nasal congestion and epistaxis Increased O₂ consumption to meet increased metabolic requirements Elevated diaphragm i.e. patient appears more “barrel-chested” Increased minute ventilation leads to decreased CO₂, resulting in mild respiratory alkalosis that helps CO₂ diffuse across the placenta from fetal to maternal circulation No change in VC and FEV; Decreased TLC, FRC, and RV</td>
</tr>
<tr>
<td>Gastrointestinal</td>
<td>GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying) Increased gallstones due to progesterone causing increased gallbladder stasis Constipation and hemorrhoids due to progesterone causing decreased GI motility</td>
</tr>
<tr>
<td>Genitourinary</td>
<td>Increased urinary frequency due to increased total urinary output Increased incidence of UTI and pyelonephritis due to urinary stasis (see Urinary Tract Infection, OB20) Glycosuria that can be physiologic especially in the 3rd trimester; must test for GDM Ureters and renal pelvis dilation (R&gt;L) due to progesterone-induced smooth muscle relaxation and uterine enlargement Increased CO and thus increased GFR leads to decreased creatinine (normal in pregnancy 35-44 mmoL, uric acid, and BUN</td>
</tr>
<tr>
<td>Neurologic</td>
<td>Increased incidence of carpal tunnel syndrome and Bell’s palsy</td>
</tr>
<tr>
<td>Endocrine</td>
<td>Thyroid: moderate enlargement and increased basal metabolic rate Increased total thyroxine and thyroxine binding globulin (TBG) Free thyroxine index and TSH levels are normal Adrenal: maternal cortisol rises throughout pregnancy (total and free) Calcium: decreased total maternal Ca²⁺ due to decreased albumin Free ionized Ca²⁺ (i.e. active) proportion remains the same due to parathyroid hormone (PTH), results in increased bone resorption and gut absorption, increased bone turnover (but no loss of bone density due to estrogen inhibition)</td>
</tr>
</tbody>
</table>
Prenatal Care

- provided by obstetrician, family doctor, midwife, or multidisciplinary team (based on patient preference and risk factors)
- Antenatal Records (province specific)

Preconception Counselling

- 3-8 wk GA is a critical period of organogenesis, so early preparation is vital
- past medical history: optimize medical illnesses and necessary medications prior to pregnancy (see Medical Conditions in Pregnancy, OB13, and Medications in Pregnancy, OB10)

- supplementation
  - folic acid: encourage diet rich in folic acid and supplement 8-12 wk preconception until end of T1 to prevent NTDs
    - 0.4-1 mg daily in all women, 5 mg if previous NTD, anti-epileptic medications, diabetes mellitus or BMI >35 kg/m²
  - iron supplementation, prenatal vitamins

- risk modification
  - lifestyle: balanced nutrition and physical fitness
  - medications: patients with chronic diseases should discuss whether their medications may be teratogenic prior to conception so they may be adjusted. It is not advised to stop medications abruptly when becoming pregnant
  - infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV
  - genetic testing as appropriate for high risk groups (see Prenatal Screening section, Table 2, OB5); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay or birth anomalies
  - social: alcohol, smoking, drug use, domestic violence
    - use ALPHA form to screen for antenatal risk factors associated with poor postpartum family outcomes (woman abuse, child abuse, postpartum depression, marital dysfunction and increased physical illness)

Initial Prenatal Visit

- usually within 12 wk of the first day of LMP or earlier if <20 or >35 yr old or other risk factors are present
- Antenatal Records are filled out on the first prenatal visit

History

- gestational age by dates from the first day of the LMP
- if LMP unreliable, get a dating ultrasound (see below)
- EDC using Naegle's Rule:
  - 1st day of LMP + 7 d – 3 mo
  - e.g. LMP = 1 Apr 2013, EDC = 8 Jan 2014 (modify if cycle >28 d by adding number of d >28)
- history of present pregnancy (e.g. bleeding, nausea, vomiting)
- history of all previous pregnancies
- past medical history, past gynecological history
- prescription and non-prescription medications
- family history: genetic disease, birth defects, multiple gestation
- social history: smoking, alcohol, drug use, domestic violence (use ALPHA form), consanguinity

Physical Examination

- complete exam to obtain baseline patient information
- BP and weight important for interpreting subsequent changes
- pelvic exam

Investigations

- bloodwork
  - CBC, blood group and type, Rh antibodies, infection screening as per preconception counselling
  - urine R&M, C&S
  - screen for bacteriuria and proteinuria
- pelvic exam
  - Pap smear (unless done within last 6-12 mo), cervical culture for N. gonorrhoeae (GC) and C. trachomatis, vaginal swab for bacterial vaginosis (BV)
**Subsequent Prenatal Visits**

**Timing**
- for uncomplicated pregnancies, q4-6wk until 28 wk, q2wk from 28 to 36 wk and weekly from 36 wk until delivery

**Assess at Every Visit**
- record estimated GA
- history of present pregnancy: fetal movements, uterine bleeding, leaking, cramping
- physical exam: BP, weight gain, SFH, Leopold’s maneuvers (T3) for lie, position and presentation of fetus
- investigations: urinalysis for glucosuria, ketones, proteinuria; fetal heart rate starting at 12 wk using Doppler U/S

**Leopold’s Maneuvers**
- performed after 30-32 wk gestation
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

![Figure 2. Leopold’s maneuvers (T3)](https://example.com/leopolds-maneuvers)

Reprinted with permission from Essentials of Clinical Examination Handbook, 6th ed. Lincoln, McSheffrey, Tran, Wong

**Prenatal Screening and Diagnostic Tests**

**Screening Tests**
- testing should only occur following counselling and with the informed consent from the patient

<table>
<thead>

*AR = autosomal recessive; HPLC = high performance liquid chromatography; HEXA = hexosaminidase A
*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD), if family history of a specific condition, look for carrier status: e.g., Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners positive, refer for genetic counselling

**Symphysis Fundal Height (SFH)**
- 12 wk: Uterine fundus at pubic symphysis
- 20 wk: Fundus at umbilicus, SFH should be within 2 cm of GA between 20-36 wk
- 37 wk: Fundus at sternum

**Small for Dates**
- Date miscalculation
- IUGR
- Fetal demise
- Oligohydramnios

**Large for Dates**
- Date miscalculation
- Multiple gestation
- Polyhydramnios
- LGA (familial), diabetes

Maternal serum screen is also referred to as Triple Screen. If Inhibin A is also tested, it is referred to as Quadruple Screen. Ideally testing for MSS and IPS Part 2 occur between 15-18 wk to give women more time to make decisions and move ahead with diagnostic testing should the result screen be positive.

ULTRASOUND SCREENING
- dating ultrasound best done between 8-12 wk GA (most accurate form of pregnancy dating)
  - measurement of crown-rump length (margin of error ± 5 d)
  - change EDC to U/S date if >1 wk discrepancy from EDC based on LMP
- NTUS at 11-14 wk GA
  - measures the amount of fluid behind the neck of the fetus
  - early screen for Trisomy 21 (may also detect cardiac and other aneuploidies like Turner’s syndrome)
  - NT measurement is necessary for the FTS and IPS Part 1
- fetal growth and anatomy ultrasound routinely done at 18-20 wk GA (margin of error ± 7 d)
  (see Pediatrics, P41 for congenital anomalies)
- earlier or subsequent ultrasounds performed when medically indicated

<tr>
<td>Risk estimate for 1. Down syndrome (Trisomy 21): increased NT, increased β-hCG, decreased PAPP-A</td>
<td>Risk estimate for 1. oNTD: increased MSAFP (sensitivity 80-90%) 2. Trisomy 21: decreased MSAFP, increased β-hCG, decreased µE3 (sensitivity 65%) 3. Trisomy 18: decreased MSAFP, decreased β-hCG, decreased µE3 (sensitivity 80%)</td>
<td>Risk estimate for oNTD, Trisomy 21, Trisomy 18 Sensitivity -- 85-90% 2% false positive rate Patients with positive screen should be offered U/S and/or amniocentesis</td>
</tr>
<tr>
<td>Note: does not measure risk of open neural tube defect (oNTD) and should be combined with MSAFP at 16 wk Useful where patient wants results within the first trimester More accurate estimate of Down syndrome risk than MSS, sensitivity ~85% (when combined with age) 9% false positive rate Patients with positive screen should be offered CVS or amniocentesis</td>
<td>Only offered alone if patient missed the time window for IPS or FTS 8% baseline false positive rate for Trisomy 21, lower for oNTD and Trisomy 18 Patients with positive screen should be offered U/S or amniocentesis</td>
<td></td>
</tr>
</tbody>
</table>

Note: In twins, FTS, MSS and IPS are not applicable; screen with NT for chromosomal abnormalities and MSAFP for oNTDs.
**DIAGNOSTIC TESTS**

**Indications**
- Maternal age >35 (increased risk of chromosomal anomalies)
- Risk factors in current pregnancy:
  - Abnormal U/S
  - Abnormal prenatal screen (IPS, FTS, or MSS)
- Past history/family history of:
  - Previous pregnancy with chromosomal anomaly or genetic disease
  - Either parent a known carrier of a genetic disorder or balanced translocation
  - Family history of chromosomal anomaly, genetic disorder, birth defect, or undiagnosed mental retardation
  - Consanguinity
  - Three or more spontaneous abortions

**AMNIOCENTESIS**
- U/S-guided transabdominal extraction of amniotic fluid

**Indications**
- Identification of genetic anomalies (15-16 wk gestation) as per indications above
- Assessment of fetal lung maturity (T3) via the L/S ratio (lecithin:sphingomyelin)
  - If >2:1, RDS is less likely to occur

**Advantages**
- Also screens for oNTD (acetylcholinesterase and amniotic AFP) - 96% accurate
- In women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- More accurate genetic testing than CVS

**Disadvantages**
- 1/400 – 1/500 risk of spontaneous abortion
- Results take 14-28 days; FISH can be done on chromosomes X, Y, 21, 13, 18 to give preliminary results in 48 h

**CHORIONIC VILLUS SAMPLING**
- Biopsy of fetal-derived chorion using a trans-abdominal needle or trans-cervical catheter at 10-12 wk

**Advantages**
- Enables pregnancy to be terminated earlier than with amniocentesis
- Rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- High sensitivity and specificity

**Disadvantages**
- 1-2% risk of spontaneous abortion
- Does not screen for oNTD
- 1-2% incidence of genetic mosaicism “false negative” results

**ISOIMMUNIZATION SCREENING**

**Definition**
- Isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigentic stimulation with RBC of another individual

**Etiology**
- Maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
- In pregnancy, anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
- Overall risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%

**Sensitization routes**
- Incompatible blood transfusions
- Previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy)
- Invasive procedures in pregnancy (e.g. prenatal diagnosis, cerclage, D&C)
- Any type of abortion
- Labour and delivery
Investigations
- routine screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
- Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation.
- detailed U/S for hydrops fetalis

Prophylaxis
- exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
- Rhogam® (300 µg) given to all Rh negative and antibody screen negative women in the following scenarios:
  - routinely at 28 wk GA (provides protection for ~12 wk)
  - within 72 h of the birth of an Rh positive fetus
  - with a positive Kleihauer-Betke test
  - with any invasive procedure in pregnancy (CVS, amniocentesis)
  - in ectopic pregnancy
  - with miscarriage or therapeutic abortion (only 50 µg required)
  - with an antepartum hemorrhage
- if Rh negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy ± serial amniocentesis as needed (Rhogam® has no benefit)

Investigations
- MCA dopplers are done to assess degree of fetal anemia or if not available bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
- cordocentesis for fetal Hb should be used cautiously (not first line)

Treatment
- falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
- intrauterine transfusion of O-negative pRBCs may be required for severely affected fetus or early delivery of the fetus for exchange transfusion

Complications
- anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
- severe cases can lead to fetal hydrops (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)

GROUP B STREPTOCOCCUS SCREEN

Epidemiology
- 15-40% vaginal carrier rate

Risk Factors (for neonatal disease)
- GBS bacteriuria during current pregnancy even if treated
- previous infant with invasive GBS infection
- preterm labour <37 wk
- ruptured membranes >18 h before delivery
- intrapartum maternal temperature ≥38°C
- positive GBS screen during current pregnancy

Clinical Features
- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)

Investigations
- offer screening to all women at 35-37 wk with vaginal and anorectal swabs for C&S

Treatment
- treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
- indications for antibiotic prophylaxis: positive GBS screen or GBS status unknown and one of the risk factors (see above)
- antibiotics for GBS prophylaxis
  - penicillin G 5 million units IV then 2.5 million units IV q4h until delivery
  - penicillin allergic but not at risk for anaphylaxis: cefazolin 2 g IV then 1 g q8h
  - penicillin allergic and at risk for anaphylaxis: clindamycin 900 mg IV q8h or erythromycin 500 mg IV q6h
- if fever, broad spectrum antibiotic coverage is advised

Indications for Intrapartum Antibiotic GBS Prophylaxis
- • Previous infant with invasive GBS disease
- • GBS bacteriuria during any trimester of the current pregnancy
- • Positive GBS vaginal-rectal screening culture in late gestation during current pregnancy
- • Unknown GBS status at the onset of labour (culture not done, incomplete, or results unknown) and any of the following:
  - Delivery at <37 wk gestation
  - Amniotic membrane rupture ≥18 h
  - Intrapartum temperature ≥100.4°F (≥38.0°C)
  - Intrapartum nucleic-acid amplification test positive for GBS

Rh Antibody Titre
- A positive titre (≥1:16) indicates an increased risk of fetal hemolytic anemia.

Standard dose of 300 µg of Rhogam sufficient for 30 mL of fetal blood. Give additional 10 µg of Rhogam for every mL of fetal blood over 30 mL.
Counselling of the Pregnant Woman

Nutrition

- Canada’s Food Guide to Healthy Eating suggests:
  - 3–4 servings of milk products daily (greater if multiple gestation)
  - a daily caloric increase of ~100 cal/d in the 1st trimester, ~300 cal/d in the second and third trimesters and ~450 cal/d during lactation
  - daily multivitamin should be continued in the 2nd trimester for women who do not consume an adequate diet; otherwise routine vitamin supplementation is not necessary (avoid excess vitamin A)

- nutrients important during pregnancy
  - folate: 0.4 mg/d for first 12 wk (5 mg/d if high risk)
    - supports maternal increase in blood volume, growth of maternal and fetal tissue, decreases incidence of neural tube defects
    - foods rich in folic acid include: spinach, lentils, chick peas, asparagus, broccoli, peas, Brussels sprouts, corn and oranges
  - calcium: 1200-1500 mg/d
    - maintains integrity of maternal bones, skeletal development of fetus, breast milk production
  - vitamin D: 1000 IU
    - promotes calcium absorption
  - iron: 0.8 mg/d in T1, 4-5 mg/d in T2 and >6 mg/d in T3
    - supports maternal increase in blood cell mass, supports fetal and placental tissue
    - required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
    - iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (see Iron Deficiency Anemia, OB13)
  - essential fatty acids – supports fetal neural and visual development
    - contained in vegetable oils, margarines, peanuts, fatty fish

Caffeine

- diuretic and stimulant that readily crosses placenta
- less than 200 mg per day is not thought to contribute to miscarriage or preterm birth (ACOG)
- relationship between caffeine and IUGR is unknown (ACOG)
- SOCG states 1-2 cups/d are safe during pregnancy

Herbal Teas and Preparations

- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- chamomiles have been reported to exhibit adverse effects on the uterus

Food Borne Illnesses

- microbiological contamination of food may occur through cross-contamination and/or improper food handling
  - listeriosis (Listeria monocytogenes) and toxoplasmosis (Toxoplasma gondii) are of concern during pregnancy
  - avoid consumption of raw meats, fish, poultry, raw eggs, and unpasteurized dairy products
  - avoid soft cheeses, deli meats, smoked salmon and pates as they may be sources of Listeria
- chemical contamination of food
  - current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
  - Health Canada advises pregnant women to limit consumption of top predator fish such as shark, swordfish, king mackerel, tilefish, and fresh/frozen tuna (not canned tuna) to one meal per month

Lifestyle

- exercise under physician guidance
- absolute contraindications
  - ruptured membranes, preterm labour, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28th wk, persistent 2nd or 3rd trimester bleeding, uncontrolled type 1 diabetes, uncontrolled thyroid disease, or other serious cardiovascular, respiratory or systemic disorder
- relative contraindications
  - previous preterm birth, mild/moderate cardiovascular or respiratory disorder, anemia (Hb ≤100 g/L), malnutrition or eating disorder, twin pregnancy after 28th wk, other significant medical conditions
- weight gain: optimal gain depends on pre-pregnancy weight (varies from 6.8-18.2 kg)
- work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
- travel: not harmful, but stress related to travel may be associated with preterm labour
  - air travel is acceptable in second trimester; airline cutoff for travel is 36-38 wk gestation depending on the airline to avoid giving birth on the plane
- smoking: assist/encourage to reduce or quit smoking
  - increased risk of: decreased birth weight, placenta previa/abruption, spontaneous abortion, preterm labour, stillbirth
- alcohol: no amount of alcohol is safe in pregnancy. Encourage abstinence from alcohol during pregnancy; alcohol increases incidence of abortion, stillbirth, and congenital anomalies
  - fetal alcohol syndrome (see Pediatrics, P24)
- cocaine: microcephaly, growth retardation, prematurity, abruptio placentae

### Medications

- most drugs cross the placenta to some extent
- very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
- use any drug with caution and only if necessary
- analgesics: acetaminophen preferable to ASA or ibuprofen

#### Table 5. Documented Adverse Effects, Contraindicated

<table>

<td>chloramphenicol</td>
<td>Grey baby syndrome (fetal circulatory collapse 2° to toxic accumulation)</td>
</tr>
</tbody>
</table>

### Immunizations

#### Intrapartum

- administration is dependent on the risk of infection vs. risk of immunization complications
- safe: tetanus toxoid, diphtheria, influenza, hepatitis B
- avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, varicella
- contraindicated: rubella, oral typhoid

#### Postpartum

- rubella vaccine for all non-immune mothers
- hepatitis B vaccine should be given to infant within 12 h of birth if maternal status unknown or positive – follow-up doses at 1 and 6 mo
- human papillomavirus (HPV) vaccine – if meets criteria
Radiation

- Ionizing radiation exposure is considered teratogenic at high doses
  - If indicated for maternal health, should be done
- Imaging not involving direct abdominal/pelvic high dosage is not associated with adverse effects
  - Higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen, pelvis, lumbar spine
- Most investigations involve minimal radiation exposure (see Table 7)
- Radioactive isotopes of iodine are contraindicated
- No known adverse effects from US or MRI

Adapted from Cohen-Kerem, et al. 2005 and Valentin, 2000

Termination of Pregnancy

- See **Gynecology: GY9**

**Definition**

Active termination of a pregnancy before fetal viability (usually <500 g or 20 wk GA)

**Indications**

- Inability to carry a pregnancy to term due to medical or social reasons (including patient preference)

**Management**

- Medical
  - <9 wk: methotrexate + misoprostol
  - >12 wk: prostaglandins (intra- or extra-amniotically or IM) or misoprostol
- Surgical
  - <12 wk: dilatation + vacuum aspiration ± curettage
  - >12 wk: dilatation and evacuation, early induction of labour
  - Common complications: pain or discomfort
  - Less common complications: hemorrhage, perforation of uterus, laceration of cervix, risk of infertility, infection/endometritis, Asherman’s syndrome (adhesions within the endometrial cavity causing amenorrhea/infertility), retained products of conception
- Counselling
  - Supportive and counselling services
  - Future contraception and family planning services
  - Ensure follow-up

**CMA policy (1988)**

“Induced abortion should be uniformly available to all women in Canada” and “there should be no delay in the provision of abortion services.”

Terminations are generally done until the stage of viability (~23.5 wk), although this varies depending on the provider.

**Induced Abortion Statistics**

- Rate per 1,000 women (all ages): 13.7
- 31.4% of all abortion services are accessed by women aged 20-24

Adapted from Statistics Canada. Induced abortion statistics. 82-223-XWE, 2005/16
Prenatal Fetal Monitoring

Fetal Movements

- Patients will generally first notice fetal movement ("quickening") at 18-20 wk in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus.
- If the patient is concerned about decreased fetal movement, she is counselled to choose a time when the fetus is normally active to count movements (usually recommended after 28 wk).
  - If there is a subjective decrease in fetal movement, try drinking juice, eating, changing position or moving to a quiet room and count for 2 h. There should be ≥6 movements in 2 h.
  - If there are <6 movement counts in 2 h, patient should present to labour and delivery triage.

NON-STRESS TEST (NST)

Definition

- FHR tracing ≥20 min using an external Doppler to assess FHR and its relationship to fetal movement (see Fetal Monitoring in Labour, OB34).

Indication

- Any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being.

Table 8. Classification of Antepartum Non-Stress Test

<table>
<thead>

</tr>
</tbody>
</table>

Adapted from SOGC, Fetal Health Surveillance: Antepartum and Intrapartum Consensus Guideline, September 2007

Operating Characteristics

- False positive rate depends on duration; false negative rate = 0.2-0.3%

Interpretation

- Normal: at least 2 accelerations of FHR >15 bpm from the baseline lasting >15 s, in 20 min.
- Abnormal: <2 accelerations of FHR in 40 min.
- If no observed accelerations or fetal movement in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min.
- If NST abnormal, then perform BPP.

BIOPHYSICAL PROFILE

Definition

- U/S assessment of the fetus ± NST

Indications

- Abnormal or atypical NST
- Post-term pregnancy
- Decreased fetal movement
- Any other suggestion of fetal distress or uteroplacental insufficiency
Operating Characteristics
• false positive rate ≤30%, false negative rate = 0.1%

Table 9. Scoring of the BPP

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Reassuring (2 points)</th>
<th>Non-Reassuring (0 points)</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFV*</td>
<td>Fluid pocket of 2 cm in 2 axes</td>
<td>Oligohydramnios</td>
</tr>
<tr>
<td>Breathing</td>
<td>At least one episode of breathing lasting at least 30 s</td>
<td>No breathing</td>
</tr>
<tr>
<td>Limb Movement</td>
<td>Three discrete movements</td>
<td>Two or less</td>
</tr>
<tr>
<td>Fetal Tone</td>
<td>At least one episode of limb extension followed by flexion</td>
<td>No movement</td>
</tr>
</tbody>
</table>

*AFV is a marker of chronic hypoxia, all other parameters indicate acute hypoxia

Interpretation
• 8: perinatal mortality rate 1:1000; repeat BPP as clinically indicated
• 6: perinatal mortality 31:1000; repeat BPP in 24 h
• 0-4: perinatal mortality rate 200:1000; deliver fetus if benefits of delivery outweigh risks

Medical Conditions in Pregnancy

Iron and Folate Deficiency Anemia

</tr>
<tr>
<td>Investigations</td>
<td>See Hematology, H14</td>
</tr>
<tr>
<td>Management</td>
<td>Prevention (non-anemic): 30 mg elemental iron/d (met by most prenatal vitamins) Treatment (anemic): 30-120 mg elemental iron/d 325 mg ferrous fumarate = 106 mg elemental Fe²⁺; 325 mg ferrous sulfate = 65 mg elemental Fe²⁺; 325 mg ferrous gluconate = 36 mg elemental Fe²⁺</td>
</tr>
<tr>
<td>Complications</td>
<td>Maternal: angina, CHF, infection, slower recuperation, preterm labour Fetal: decreased oxygen carrying capacity leading to fetal distress, IUGR and low birth weight</td>
</tr>
<tr>
<td>Notes</td>
<td>Mother needs 1 g of elemental iron per fetus; this amount exceeds normal stores + dietary intake Iron requirements increase during pregnancy due to fetal/placental growth (500 mg), increased maternal RBC mass (500 mg) and losses (200 mg) – more needed for multiple gestations</td>
</tr>
</tbody>
</table>

Diabetes Mellitus (DM)

Classification of Diabetes Mellitus
• Type 1 and Type 2 DM (see Endocrinology, E6)
• GDM: onset of diabetes mellitus during pregnancy

Etiology
• Type 1 and Type 2 DM
• GDM: usually around 24-28 wk GA, anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance → higher fasting glucose → leading to GDM and/or exacerbating pre-existing DM

Epidemiology
• 2-4% of pregnancies are complicated by DM
MANAGEMENT

A. TYPE 1 AND TYPE 2 DM

Preconception
- pre-plan and refer to high-risk clinic
- optimize glycemic control
- counsel patient re: potential risks and complications
- evaluate for diabetic retinopathy, neuropathy, coronary artery disease

Pregnancy
- if already on oral medication, generally switch to insulin therapy
  - continuing glyburide or metformin controversial
  - teratogenicity unknown for other oral anti-hyperglycemics
- tight glycemic control
  - insulin dosage may need to be adjusted in T2 due to increased demand and increased insulin resistance
- monitor as for normal pregnancy plus initial 24 h urine protein and creatinine clearance, retinal exam, HbA1c
  - HbA1c: >140% of pre-pregnancy value associated with increased risk of spontaneous abortion and congenital malformations
- increased fetal surveillance (BPP, NST)

Labour
- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose and blood pressure control)
- can wait for spontaneous labour if blood glucose well-controlled and BPP normal
- induce by 40 wk
- type of delivery
  - increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4,000 g (8.8 lbs)
  - elective C/S for predicted birthweight >4,500 g (9.9 lbs) (controversial)
- monitoring
  - during labour monitor blood glucose q1h with patient on insulin and dextrose drip
  - aim for blood glucose between 3.5 to 6.5 mmol/L to reduce the risk of neonatal hypoglycemia

Postpartum
- insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
- no insulin is required for 48-72 h postpartum in most Type 1 DM
- monitor glucose q6h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >8 mmol/L

B. GESTATIONAL DIABETES MELLITUS

Screening + Diagnosis
- at 24-28 wk GA
- pregnant females age >25 or age <25 yr with >1 risk factor (see sidebar)
- 1 h, 50 g Oral Glucose Challenge Test (OGCT): not fasting
  - PG <7.8 mmol/L = no GDM
  - PG ≥7.8-10.3 mmol/L = further investigation with OGTT
  - PG ≥10.3 mmol/L = GDM
- 2 h, 75 g Oral Glucose Tolerance Test (OGTT): fasting
  - FPG ≥5.3 mmol/L
  - PG 1 h ≥10.6 mmol/L
  - PG 2 h ≥8.9 mmol/L
  - 2/3 of the above = GDM
  - 1/3 of the above = impaired glucose tolerance (IGT)

Management
- treat both GDM and IGT
- first line is management through diet modification and increased physical activity
- tight glycemic control optimal as in Type 1 and Type 2 DM
- monitoring and timing of delivery as for Type 1 and Type 2 DM
- stop insulin and diabetic diet postpartum
- follow-up with 2 h, 75 g OGTT 6 wk-6 mo postpartum

Risk Factors for GDM:
- Age >25
- Obesity
- Ethnicity (Aboriginal, Hispanic, Asian, African)
- FHx of DM
- Previous history of GDM
- Previous child with birthweight >4.0 kg
- Polycystic ovarian syndrome
- Current use of glucocorticoids
- Essential hypertension or pregnancy-related hypertension

Postprandial blood glucose values seem to be the most effective at determining the likelihood of macrosomia or other adverse pregnancy outcomes.
Prognosis
• most maternal and fetal complications are related to hyperglycemia and its effects

Long Term Maternal Complications
• Type 1 and Type 2 DM: risk of progressive retinopathy and nephropathy
• GDM: 50% risk of developing Type 2 DM in next 20 yr

Table 11. Complications of DM in Pregnancy

</tbody>
</table>

Labour and Delivery
• Preterm labour/prematurity: most commonly in patients with hypertension/preeclampsia. Preterm labour is associated with poor glycemic control but the exact mechanism is unknown
• Increased incidence of stillbirth
• Birth trauma: due to macrosomia, can lead to difficult vaginal delivery and shoulder dystocia

Neonatal
• Hypoglycemia: due to pancreatic hyperplasia and excess insulin secretion in the neonate
• Hyperbilirubinemia and jaundice: due to prematurity and polycythemia
• Hypocalcemia: exact pathophysiology not understood, may be related to functional hypoparathyroidism
• Polycythemia: hyperglycemia stimulates fetal erythropoietin production

**Hypertension in Pregnancy**

• hypertensive disorders of pregnancy are classified as either preexisting or gestational hypertension

**PRE-EXISTING HYPERTENSION**

Definition
• HTN (>140/90) prior to 20 wk GA, persisting >7 wk postpartum
• essential hypertension is associated with an increased risk of gestational HTN, abruptio placenta, IUGR and intrauterine fetal demise (IUFD)

**GESTATIONAL HYPERTENSION**

Definition
• sBP >140 or dBP >90 developing after 20th wk GA in a woman known to be normotensive before pregnancy

Risk Factors
• maternal factors
  • primigravida (80-90% of gestational HTN)
  • first conception with a new partner
  • PMHx or FHx of gestational HTN
  • DM, chronic HTN, or renal insufficiency
  • Antiphospholipid syndrome
  • extremes of maternal age (<18 or >35 yr)
• fetal factors
  • IUGR or oligohydramnios, GTN, multiple gestation, fetal hydrops
  • previous stillbirth or intrauterine fetal demise
Clinical Evaluation of Hypertension in Pregnancy

- in general, clinical evaluation should include the mother and fetus
- evaluation of mother:
  - body weight
  - central nervous system
    - presence and severity of headache
    - visual disturbances – blurring, scotomata
    - tremulousness, irritability, somnolence
    - hyperreflexia
  - hematologic
    - bleeding, petechiae
  - hepatic
    - RUQ or epigastric pain
    - severe nausea and vomiting
  - renal
    - urine output and colour
    - non-dependent edema (i.e. hands and face)
- evaluation of fetus:
  - fetal movement
  - fetal heart rate tracing – NST
  - ultrasound for growth
  - biophysical profile
  - Doppler flow studies

Laboratory Evaluation of Gestational Hypertension

- hemoglobin, platelets, blood film
- PTT, INR, fibrinogen, D-dimer – especially if surgery or regional anesthetics are planned
- ALT, AST, LDH, bilirubin
- proteinuria, creatinine, uric acid
- 24 h urine collection for total protein and creatinine clearance

Complications

- maternal
  - liver and renal dysfunction
  - seizure
  - abruptio placentae
  - left ventricular failure/pulmonary edema
  - DIC (release of placental thromboplastin consumptive coagulopathy)
  - HELLP syndrome (see Table 12, OB19)
  - treat with FFP infusion or plasma exchange
  - hemorrhagic stroke (50% of deaths)
- fetal (2° to placental insufficiency)
  - IUGR, prematurity, abruptio placentae, IUFD

Management

- for both preexisting and gestational hypertension, labetalol 100-300 mg PO bid/tid, nifedipine, 30-50 mg PO daily or α-methyldopa 250-500 mg PO tid/qid
- no ACE inhibitors, diuretics or propanolol (teratogens)
- preexisting HTN and gestational HTN without any deterioration can be followed until 37 wk then decide to induce shortly thereafter

PREECLAMPSIA

Definition

- pre-existing or gestational hypertension with new onset proteinuria or adverse conditions

Risk Factors

- nulliparity
- preeclampsia in a previous pregnancy
- age >40 yr or <18 yr
- FHx of preeclampsia
- chronic HTN
- chronic renal disease
- antiphospholipid antibody syndrome or inherited thrombophilia
- vascular or connective tissue disease
- diabetes mellitus (pregestational and gestational)
- high BMI
- hydrops fetalis

- For BP measurement, Korotkoff phase V should be used to designate the dBP
- For preeclampsia prevention among low-risk women with low dietary calcium intake (<600 mg/d), oral calcium supplementation of at least 1 g/d is recommended
- For preeclampsia prevention among increased risk women, low-dose Aspirin® (75-100 mg/d) is recommended until delivery
- Umbilical artery Doppler velocimetry should be part of the antenatal/fetal surveillance in preeclampsia
- Initial antihypertensive therapy for severe hypertension (sBP >160 mmHg or dBP ≥110) should be with labetalol, nifedipine, or hydralazine
- Initial antihypertensive therapy for non-severe hypertension (sBP 140-159/90-109 mmHg) should be with methyladopa, β-blockers, or calcium channel blockers
- Antenatal corticosteroids for fetal lung maturation should be considered for all women with preeclampsia before 34 wk gestation
- In a planned vaginal delivery with an unfavourable cervix, cervical ripening should be used
- Oxycin 5 units IV or 10 units IM should be used as part of the management during the third stage of labour
- MgSO₄ is the recommended first-line treatment for eclampsia
- MgSO₄ is the recommended eclampsia prophylaxis in severe preeclampsia

Hypertension in Pregnancy

Adverse Maternal Conditions

- sBP >160 mmHg
- dBP >100 mmHg
- HELLP
- Cerebral haemorrhage
- Renal dysfunction: oliguria <500 mL/d
- Left ventricular failure, pulmonary edema
- Abruption, DIC

Symptoms:

- Abdominal pain, nausea, vomiting
- Headaches, visual problems
- SOB, chest pain
- Eclampsia: convulsions

Adverse Fetal Conditions

- Intrauterine growth restriction
- Oligohydramnios
- Absent/reversed umbilical artery end diastolic flow

Can result in:

- Fetal disability and/or death
• unexplained fetal growth restriction
• abruptio placentae
• there is a potential for further deterioration to severe preeclampsia as defined above (see Figure 3)
• the adverse conditions are many and include both maternal and fetal issues (see sidebar, OB15)

Management
• management will depend on GA, possible threat of seizures (check reflexes)
• if stable and no adverse factors, may admit and follow, ± decide to deliver as approaching 34-36 wk (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/eclampsia)
• for severe preeclampsia, stabilize and deliver
• if severe preeclampsia, during labour, increase maternal monitoring: hourly input and output, urine dip q12h, hourly neurological vitals, and increase fetal monitoring (continuous FHR monitoring)
• antihypertensive therapy
  ▪ lowering BP decreases the risk of stroke
  ▪ hydralazine 5-10 mg IV bolus over 5 min q15-30min as necessary
  ▪ labetalol 20-50 mg IV q10min
  ▪ 2nd line: nifedipine 10-20 mg PO q20-60min
• seizure prevention
  ▪ MgSO₄
  ▪ postpartum management
  ▪ risk of seizure highest in first 24 h postpartum – continue MgSO₄ for 12-24 h after delivery
  ▪ vitals q1h
  ▪ consider HELLP syndrome in toxic patients
  ▪ most return to a normotensive BP within 2 wk

ECLAMPSIA

Definition
• the occurrence of one or more generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

Epidemiology
• an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic women and 2-3% of severely preeclamptic women

Risk Factors
• same as risk factors for Preeclampsia, see above

Clinical Manifestations
• eclampsia is a clinical diagnosis
• typically tonic-clonic and lasting 60-75 s
• one of the signs of an impending seizure is hyperreflexia
• symptoms that may occur before the seizure include persistent frontal or occipital headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
• in up to one third of cases, there is no proteinuria or blood pressure is less than 140/90 mmHg prior to the seizure
• in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

Management
• ABCs
• roll patient into LLDP
• supplemental O₂ via face mask to treat hypoxemia due to hypoventilation during convulsive episode
• aggressive antihypertensive therapy for sustained diastolic pressures ≥105 mmHg or systolic blood pressures ≥160 mmHg with hydralazine or labetalol
• prevention of recurrent convulsions: to prevent further seizures and the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.) MgSO₄ is now the drug of choice, with previously used agents including diazepam and phenytoin
• the definitive treatment of eclampsia is DELIVERY, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease
• mode of delivery is dependent on clinical situation and fetal-maternal condition

Differential Diagnosis of Cause for Seizure in a Pregnant Woman

• Stroke
• Hypertensive disease (hypertensive encephalopathy, pheochromocytoma)
• Space-occupying lesion of the CNS
• Metabolic disorders (hypoglycemia, SIADH)
• Infection (meningitis, encephalitis)
• Idiopathic epilepsy
• Use of illicit drugs
• Cerebral vasculitis

Note
Eclampsia prior to 20 wk of gestation is rare and should raise the possibility of an underlying molar pregnancy or antiphospholipid syndrome.

MgSO₄ toxicity

<td>Note: Increased risk of toxicity with concurrent calcium channel blocker use or renal disease</td>
</tr>
</tbody>
</table>

Treatment:

• Stop MgSO₄
• Calcium gluconate 10% in 10 mL via IV
Nausea and Vomiting

Epidemiology
- affects 50-90% of pregnant women
- often limited to T1 but may persist

Management
- r/o other causes of N/V
- weigh frequently, assess level of hydration, test urine for ketones
- non-pharmacological:
  - avoid mixing fluids and solids, frequent small meals
  - stop prenatal vitamins (folic acid must continue until >12 wk)
  - increase sleep/rest
  - ginger (maximum 1000 mg/d)
  - acupuncture, acupressure
- pharmacological:
  - first line: Diclectin® (10 mg doxylamine succinate with vitamin B₆) 4 tablets PO daily to maximum of 8 tablets
  - if no improvement, try dimenhydrinate (50-100 mg q4-6h PO), followed by hydroxyzine, pyridoxine, phenothiazine, or metoclopramide
  - vitamin B₆ lollipops
  - if patient dehydrated, assess fluid replacement needs and resuscitate accordingly
- severe/refractory:
  - consider homecare with IV fluids and parenteral anti-emetics, hospitalization

Hyperemesis Gravidarum

Definition
- intractable nausea and vomiting, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
- affects ~1% of pregnancies

Etiology
- multifactorial with hormonal, immunologic and psychologic components
- rapidly rising β-hCG ± estrogen levels may be implicated

Investigations
- r/o systemic causes: GI inflammation, pyelonephritis, thyrotoxicosis
- r/o obstetrical causes: multiple gestation, GTN, HELLP syndrome
- CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
- ultrasound

Management
- thiamine supplementation may be indicated
- non-pharmacological: (see Nausea and Vomiting, above)
- pharmacological options
  - Diclectin® (see dosage Nausea and Vomiting, above)
  - Dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository bid or 25 mg PO qid)
  - other adjuncts: hydroxyzine, pyridoxine, phenothiazine, metoclopramide
  - also consider: ondansetron or methylprednisolone
  - if severe: admit to hospital, NPO initially then small frequent meals, correct hypovolemia, electrolyte disturbance and ketosis, TPN (if very severe) to reverse catabolic state

Complications
- maternal
  - dehydration, electrolyte and acid-base disturbances
  - Mallory-Weiss tear
  - Wernicke's encephalopathy, if protracted course
  - death
- fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight
Jaundice in Pregnancy

Epidemiology
- affects 1 in 1500 pregnancies

Etiology
- viral hepatitis (most common)
- unique to pregnancy (see Table 12)
- cholestatic jaundice of pregnancy
- HELLP syndrome
- hepatic rupture, hematoma and infarct
- AFLP
- hyperemesis gravidarum (rarely causes hepatic dysfunction)
- pre-existing conditions (see Gastroenterology, Liver/Biliary Tract, G28, G40)

<table>
<thead>
<tr>
<th>HELLP Syndrome</th>
<th>Cholestatic Jaundice of Pregnancy</th>
<th>Hepatic Infarct, Hematoma, and Rupture</th>
<th>Acute Fatty Liver of Pregnancy (AFLP)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Hemolysis, elevated liver enzymes, low platelets Pathogenesis unknown</td>
<td>Clinical syndrome characterized by intense pruritus that precedes jaundice by 7-14 d Pathogenesis unknown, may be due to increased sensitivity to high levels of estrogen or abnormal progesterational steroids</td>
<td>Rare consequence of preeclampsia, typically occurring in T3 Vasospasm-induced hepatic infarction can lead to hematoma formation; hematoma can lead to rupture</td>
</tr>
<tr>
<td>Epidemiology</td>
<td>Affects 20% of women with severe preeclampsia Presents &gt;27 wk GA (11% sooner); up to 30% of cases present AFTER delivery and with no previous signs of hypertension</td>
<td>17-29 wk GA High incidence in Chile and Scandinavia; rare in Asian and African populations</td>
<td>1 in 7,000 deliveries 3rd trimester (28-40 wk GA) Maternal mortality as high as 75%; resolution of hepatic dysfunction with delivery or termination of pregnancy</td>
</tr>
<tr>
<td>Clinical Features</td>
<td>Epigastric, RUQ or chest pain, N/V, symptoms of preeclampsia (headache, blurred vision, thirst) ± jaundice Atypical presentations: asymptomatic reduction in platelet count, &quot;flu-like&quot; symptoms</td>
<td>Intense pruritus (usually, worst on palms and soles of feet) ± icterus (1-2 wk later) Steatorrhea unusual</td>
<td>Hemoperitoneum (paracentesis, U/S, CT, MRI showing ruptured liver) Acute nausea/vomiting, severe upper abdominal pain preceding jaundice Confusion Preeclampsia Pruritus Range in presentation: • Mild to fulminant</td>
</tr>
<tr>
<td>Investigations</td>
<td>AST (70-663 U/L), total bilirubin slightly increased, low platelet count (7-99), elevated LDH ± elevated D-dimers, tissue polypeptide antigen (TPA) and fibronectin, fragmented RBCs on smear Liver biopsy (rarely done)</td>
<td>ALT &lt;500 IU, ALP and GGT markedly elevated (to levels consistent with moderate to severe cholestasis)</td>
<td>Elevated PTT and low serum fibrinogen AST &gt; ALT Hypoglycemia Preeclampsia and HELLP features Liver biopsy to establish diagnosis • If liver biopsy not possible, CT most useful</td>
</tr>
<tr>
<td>Management</td>
<td>Supportive care (in ICU) and prompt delivery</td>
<td>Ursodeoxycholic acid (20-25 mg/kg/d) Pruritus: cholestyramine Prophylactic vitamin K before delivery Consider induction of labour (see Induction of Labour, OB36)</td>
<td>Aggressive: rapid delivery and trauma surgery to repair liver</td>
</tr>
<tr>
<td>Notes</td>
<td>Complications: sepsis, multi-system organ failure, hepatic failure, DIC, death (rare)</td>
<td>Selenium may be protective against cholestasis Strong familial predisposition Correlates with oral contraceptive sensitivity</td>
<td>Complications include death (mother and fetus) if untreated</td>
</tr>
</tbody>
</table>
Urinary Tract Infection (UTI)

Etiology
- increased urinary stasis from mechanical and hormonal (progesterone) factors
- organisms include GBS as well as those that occur in non-pregnant women

Epidemiology
- most common medical complication of pregnancy
- asymptomatic bacteriuria in 2-7% of pregnant women, more frequently in multiparous women
- note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis.

Clinical Features
- may be asymptomatic
- dysuria, urgency, and frequency in cystitis
- fever, flank pain, costovertebral angle tenderness in pyelonephritis

Investigations
- urinalysis, urine C&S
- cystoscopy, and renal function tests in recurrent infections

Management
- uncomplicated UTI
  - first line: amoxicillin (250-500 mg PO q8h x 7 d)
  - alternatives: nitrofurantoin (100 mg PO bid x 7 d)
  - follow with monthly urine cultures
- pyelonephritis
  - hospitalization and IV antibiotics

Prognosis
- complications if untreated: acute cystitis, pyelonephritis, and possible PPROM
- recurrence is common

<td>All pregnant women are offered screening</td>
</tr>
<tr>
<td>*Rubella</td>
<td>ssRNA togavirus</td>
<td>To mom: respiratory droplets (highly contagious) To baby: transplacental</td>
<td>T1</td>
<td>SA or congenital rubella syndrome (hearing loss, cataracts, CV lesions, MR, IUGR, hepatitis, CNS defects, osseous changes)</td>
<td></td>
<td>Serologic testing; all pregnant women screened (immune if titre &gt;1:16); infection if IgM present or &gt;4x increase in IgG</td>
<td>No specific treatment; offer vaccine following pregnancy</td>
</tr>
<tr>
<td>Syphilis</td>
<td>Spirochete</td>
<td>To mom: sexual contact To baby: transplacental</td>
<td>T1-T3</td>
<td>Risk of PTL, multisystem involvement, fetal death</td>
<td></td>
<td>VDRL screening for all pregnancies; if positive, requires confirmatory testing</td>
<td>Pen G 2.4 M U IM 1 dose if early syphilis 3 doses if late syphilis, monitor VDRL, monthly if Pen G allergic; Clindamycin 500mg IV q8h</td>
</tr>
<tr>
<td>*Toxoplasmosis</td>
<td>Protozoa (Toxoplasma gondii)</td>
<td>To mom: raw meat, unpasteurized goat’s milk, cat feces/urine To baby: transplacental</td>
<td>T3 (but most severe if infected in T1); only concern if primary infection during pregnancy</td>
<td>Congenital toxoplasmosis (chorioretinitis, hydrocephaly, intracranial calcification, MR, microcephaly)</td>
<td>Majority subclinical; may have flu-like symptoms</td>
<td>IgM and IgG serology; PCR of amniotic fluid</td>
<td>Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission</td>
</tr>
</tbody>
</table>

* Indicates TORCH infection

### Venous Thromboembolism (VTE)

**Epidemiology**
- incidence 0.5-3/1,000 pregnancies occurring with approximately equal frequency in all three trimesters and postpartum

**Risk Factors**
- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, thrombophilias (see Hematology, H31)
Table 14. Risk Factors for VTE Specific to Pregnancy

<table>
<thead>
<tr>

<tr>
<td>Uterus is mechanical impediment to venous return</td>
<td></td>
<td></td>
</tr>
<tr>
<td>50% decrease in venous flow in lower extremity by T3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Clinical Features
- most DVTs occur in the iliofemoral or calf veins with a predilection for the left leg
- signs of a pulmonary embolism are non-specific (as in non-pregnant women)
- unexplained spontaneous fetal loss

Investigations
- duplex venous Doppler sonography for DVT
- CXR and V/Q scan or Spiral CT for PE

Management
- before initiating treatment, obtain a baseline CBC, including platelets, and aPTT
- warfarin is contraindicated during pregnancy due to its potential teratogenic effects
- unfractionated heparin
  - bolus of 5,000 IU followed by an infusion of ~30,000 IU/24h
  - measure aPTT 6 h after the bolus
  - maintain aPTT at a therapeutic level (1.5-2 x normal)
  - repeat q24h once therapeutic
  - heparin-induced thrombocytopenia (HIT) uncommon (3%) but serious complication
  - LMWH can also be used in pregnancy
- compression stockings
- poor evidence to support a recommendation for or against avoidance of prolonged sitting
- VTE prophylaxis:
  - women on long-term anticoagulation: full therapeutic anticoagulation throughout pregnancy and for 6-12 wk postpartum
  - women with a non-active PMHx of VTE: unfractionated heparin regimens suggested
- routine VTE prophylaxis:
  - insufficient evidence in pregnancy to recommend routine use of LMWH
  - current prophylaxis regimens for acquired thrombophilias (e.g. APS syndrome) include low dose Aspirin® in conjunction with prophylactic heparin

Bleeding in Pregnancy

First and Second Trimester Bleeding

Approach to the Patient with Bleeding in T1/T2
- history
  - risk factors for ectopic pregnancy (previous ectopic pregnancies, history of STI/PID, IUD use, previous pelvic surgery, smoking)
  - previous spontaneous abortion
  - recent trauma
  - characteristics of the bleeding (including any tissue passed)
  - characteristics of the pain (cramping pain suggests SA)
  - history of coagulopathy
  - gynecological/obstetric history
  - dizziness (significant blood loss, may be associated with ruptured ectopic)
  - fever (may be associated with septic abortion)
- physical
  - vitals (including orthostatic changes)
  - abdomen (SFH, tenderness, presence of contractions)
  - perineum (signs of trauma, genital lesions)
  - speculum exam (cervical os open or closed, presence of active bleeding/clots/tissue)
  - pelvic exam (uterine size, adnexal mass, uterine/adnexal tenderness)
Investigations
- β-hCG (lower than expected for GA in spontaneous abortion (SA), ectopic pregnancy)
- U/S (confirm intrauterine pregnancy and fetal viability)
- CBC
- group and screen

Treatment
- IV resuscitation for hemorrhagic shock
- treat the underlying cause

Spontaneous Abortions
- see Termination of Pregnancy, OB11 for therapeutic abortions

Table 15. Classifications of Spontaneous Abortions

<table>
<thead>
<tr>
<th>Type</th>
<th>History</th>
<th>Clinical</th>
<th>Management (± Rhogam®)</th>

</tr>
</tbody>
</table>
| Inevitable   | Increasing bleeding and cramps ± rupture of membranes | Cervix closed until products start to expel, then external os opens U/S variable but usually nonviable fetus | a) Watch and wait 
b) Misoprostol 400-800 µg PO/PV 
c) D&C ± oxytocin |
| Incomplete   | Extremely heavy bleeding and cramps ± passage of tissue noticed | Cervix open U/S products of conception | a) Watch and wait 
b) Misoprostol 400-800 µg PO/PV 
c) D&C ± oxytocin |
| Complete     | Bleeding and complete passage of sac and placenta | Cervix open U/S no products of conception | No D&C – expectant management |
| Missed       | No bleeding (fetal death in uterus)          | Cervix closed U/S may show SGA, no fetal heart activity; nonviable fetus | a) Watch and wait 
b) Misoprostol 400-800 µg PO/PV 
c) D&C ± oxytocin |
| Recurrent    | 3+ consecutive spontaneous abortions         |                                      | Evaluate mechanical, genetic, environmental and other risk factors |
| Septic       | Contents of uterus infected – infrequent     |                                      | D&C IV broad spectrum antibiotics |

Ectopic Pregnancy

Definition
- embryo implants outside of the endometrial cavity

Epidemiology
- 1/100 pregnancies
- fourth leading cause of maternal mortality, leading cause of death in first trimester
- increase in incidence over the last 3 decades
- three commonest locations for ectopic pregnancy: ampullary (70%), isthmic (12%), fimbrial (11%)

Etiology
- 50% due to damage of fallopian tube cilia following PID
- intrinsic abnormality of the fertilized ovum
- conception late in cycle
- transmigration of fertilized ovum to contralateral tube

Clinical Features of Ectopic Pregnancy

**VFs and 15**
- Temperature >38°C (20%)
- Tenderness: abdominal (90%) ± rebound (45%)
- Tenderness on bimanual examination, cervical motion tenderness
- Tissue: palpable adnexal mass (50%) (half have contralateral mass due to lutein cyst)
- Signs of pregnancy (e.g. Chadwick’s sign, Hegar’s sign)

More than half of patients with ectopic pregnancy have no risk factors.
**Figure 3. Sites of ectopic pregnancy implantation**

Ampullary (70%) > isthmal (12%) > fimbrial (11%) > ovarian (3%) > interstitial (2%) > abdominal (1)

**Risk Factors**
- previous ectopic pregnancy
- gynecologic:
  - IUD use – increased risk of ectopic if pregnancy occurs
  - history of PID (especially infection with C. trachomatis), salpingitis
  - infertility
  - clomiphene citrate (for induction of ovulation)
- previous procedures:
  - any surgery on fallopian tube (for previous ectopic, tubal ligation, etc.)
  - abdominal surgery for ruptured appendix, etc.
  - IVF pregnancies following ovulation induction (7% ectopic rate)
- smoking
- structural:
  - uterine leiomyomas
  - adhesions
  - abnormal uterine anatomy (e.g. T-shaped uterus)

**Investigations**
- serial β-hCG levels; normal doubling time with intrauterine pregnancy is 1.6-2.4 d in early pregnancy
  - rise of <20% of β-hCG is 100% predictive of a nonviable pregnancy
  - prolonged doubling time, plateau or decreasing levels before 8 wk implies nonviable gestation but does not provide information on location of implantation
  - 85% of ectopic pregnancies demonstrate abnormal β-HCG doubling
- ultrasound
  - U/S is only definitive if fetal cardiac activity is detected in the tube or uterus
  - intrauterine sac should be visible when serum β-hCG is
    - >1,500 mIU/mL (transvaginal)
    - >6,000 mIU/mL or 6 wk GA (transabdominal)
  - specific finding on transvaginal U/S is a tubal ring
- laparoscopy (for definitive diagnosis)

**Treatment**
- goals of treatment: conservative (preserve tube if possible), maintain hemodynamic stability
- surgical (laparoscopy)
  - linear salpingostomy if tube salvageable
  - salpingectomy if tube damaged or ectopic is ipsilateral recurrence
- 15% risk of persistent trophoblast; must monitor β-hCG titre weekly until they reach non-detectable levels
- consider Rhogam® if Rh negative
- may require laparotomy if patient is unstable, extensive abdominal surgical history, etc.
• medical = methotrexate (for indications see Figure 4)
  • use 50 mg/m² body surface area, given in a single IM dose
  • this is 1/5 to 1/6 chemotherapy dose, therefore minimal side effects (reversible hepatic
dysfunction, diarrhea, gastritis, dermatitis)
  • follow β-hCG levels weekly until β-hCG is non-detectable
  • plateau or rising levels suggest persisting trophoblastic tissue (requires further treatment)
  • 82-95% success rate up to 25% will require a second dose
  • tubal patency following methotrexate treatment approaches 80%

Prognosis
• 9% of maternal deaths during pregnancy
• 40-60% of patients will become pregnant again after surgery
• 10-20% will have subsequent ectopic pregnancy

Antepartum Hemorrhage

Definition
• vaginal bleeding from 20 wk to term

Differential Diagnosis
• bloody show (shedding of cervical mucous plug) – most common etiology in T3
• placenta previa
• abruptio placenta – most common pathological etiology in T3
• vasa previa
• cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
• uterine rupture
• other: bleeding from bowel or bladder, placenta accreta, abnormal coagulation

Figure 4. Algorithm for suspected ectopic pregnancy
**Placenta Previa**

**Definition**
- placenta implanted in the lower segment of the uterus, presenting ahead of the leading pole of the fetus
- the distance of the placental edge from the internal os is described in "millimeters away" from the internal os or "millimeters of overlap" over the internal os.
- greater than 20 millimeters of overlap over the internal os in the third trimester of pregnancy is highly predictive of the need for a C section.
- any degree of overlap after 35 wk is an indication for a C section

**Clinical Features**
- PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously, but can become catastrophic
- mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
- **physical exam**
  - uterus soft and non-tender
  - presenting fetal part high or displaced
  - FHR usually normal
  - shock/anemia correspond to degree of apparent blood loss
- **complications**
  - fetal
    - perinatal mortality low but still higher than with a normal pregnancy
    - prematurity (bleeding often dictates early C/S)
    - intrauterine hypoxia (acute or IUGR)
    - fetal malpresentation
    - PPROM
    - risk of fetal blood loss from placenta, especially if incised during C/S
  - maternal
    - <1% maternal mortality
    - hemorrhage and hypovolemic shock, anemia, acute renal failure, pituitary necrosis (Sheehan syndrome)
    - placenta accreta – especially if previous uterine surgery, anterior placenta previa
    - hysterectomy

**Investigations**
- transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any gestational age
- if the placenta lies between 20 mm of overlap and 20 mm away from the internal os after 26 wk regular transvaginal ultrasounds should be repeated at regular intervals – continued change in the placental location is likely.

**Management**
- goal: keep pregnancy intrauterine until the risk of delivery < risk of continuing pregnancy
- stabilize and monitor
  - maternal stabilization: large bore IV with hydration, O2 for hypotensive patients
  - maternal monitoring: vitals, urine output, blood loss, bloodwork (hematocrit, CBC, INR/PTT, platelets, fibrinogen, FDP, type and cross match)
  - electronic fetal monitoring
  - U/S assessment: when fetal and maternal condition permit, determine fetal viability, gestational age and placental status/position
- Rhogam® if mother is Rh negative
  - Kleihauer-Betke test to determine extent of fetomaternal transfusion so that appropriate dose of Rhogam® can be given
- **GA <37 wk and minimal bleeding:** expectant management
  - admit to hospital
  - limited physical activity, no douches, enemas, or sexual intercourse
  - consider corticosteroids for fetal lung maturity
  - delivery when fetus is mature or hemorrhage dictates
- **GA ≥37 wk, profuse bleeding or L/S ratio is >2:1:** deliver by C/S
Abruptio Placentae

Clinical Features

- classification
  - total (fetal death inevitable) vs. partial
  - external/revealed/apparent: blood dissects downward toward cervix
  - internal/concealed (20%): blood dissects upward toward fetus
  - most are mixed

- presentation
  - PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractious
  - pain: sudden onset, constant, localized to lower back and uterus
  - shock/anemia out of proportion to apparent blood loss
  - ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
  - ± coagulopathy

Complications

- fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
- maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), amniotic fluid embolus

Investigations

- clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity = 15%)

Management

- maternal stabilization: large bore IV with hydration; O2 for hypotensive patients
- maternal monitoring: vitals, urine output, blood loss, bloodwork (hematocrit, CBC, PTT/PTT, platelets, fibrinogen, FDP, type and cross match)
- EFM
- blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
- Rhogam® if Rh negative
  - Kleihauer-Betke test may confirm abruption
- mild abruption:
  - GA <37 wk: use serial Hct to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
  - GA ≥37 wk: stabilize and deliver
- moderate to severe abruption:
  - hydrate and restore blood loss and correct coagulation defect if present
  - vaginal delivery if no contraindication and no evidence of fetal or maternal distress OR fetal demise
  - C/S if live fetus and fetal or maternal distress develops with fluid/blood replacement, labour fails to progress or if vaginal delivery otherwise contraindicated

Vasa Previa

Definition

- unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

Epidemiology

- 1 in 5,000 deliveries – higher in twin pregnancies

Clinical Features

- PAINLESS vaginal bleeding and fetal distress (tachy- to bradyarrhythmia)
- 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)

Investigations

- Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
- Wright stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

Management

- emergency C/S (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)
Multiple Gestation

Epidemiology
- incidence of twins is 1/80 and triplets 1/6,400 in North America
- 2/3 of twins are dizygotic (fraternal)
  - risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, ethnicity (e.g. certain African regions)
- monzygous twinning occurs at a constant rate worldwide (1/250)
- determine zygosity by number of placentas, thickness of membranes, sex, blood type

Clinical Features

Table 17. Complications Associated with Multiple Gestation

*Most common cause of perinatal mortality in multiple gestation

Management
- U/S determination of chorionicity must be done within first trimester (ideally 8-12 wk GA)
- increased antenatal surveillance
  - serial U/S q2-3wk from 28 wk GA to assess growth (uncomplicated diamniotic dichorionitic)
  - increased frequency of ultrasounds in monochorionic diamniotic and monochorionic monoamniotic twins
  - Doppler flow studies weekly if discordant fetal growth (>30%)
  - BPP as needed
- may attempt vaginal delivery if twin A presents as vertex, otherwise C/S (40-50% of all twin deliveries, 15% of cases have twin A delivered vaginally and twin B delivered by C/S)
- mode of delivery depends on fetal weight, GA, presentation

The Ps of Multiple Gestation
Complications
- Increased rates of: Puking, Pallor (anemia), Preclampsia/PIH
- Pressure (compressive symptoms)
- PTL, PROM/PROM
- Polyhydrannios
- Placenta previa/abruptio
- PPH/APH
- Prolonged labour
- Cord Prolapse
- Prematurity
- Mal Presentation
- Perinatal morbidity and mortality
- Parental distress
- Postpartum depression

Figure 6. Classification of twin pregnancies
*Indicates time of cleavage
**Twin-Twin Transfusion Syndrome**

**Epidemiology**
- 10% of monochorionic twins
- concern if >30% discordance in estimated fetal weight

**Etiology**
- arterial blood from donor twin passes through placenta into vein of recipient twin

**Clinical Features**
- donor twin: IUGR, hypovolemia, hypotension, anemia, oligohydramnios
- recipient twin: hypervolemia, hypertension, CHF, polycythemia, edema, polyhydramnios, kernicterus in neonatal period

**Investigations**
- detected by U/S screening, Doppler flow analysis

**Management**
- therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
- intrauterine blood transfusion to donor twin if necessary
- laparoscopic occlusion of placental vessels

---

**Growth Discrepancies**

**Intrauterine Growth Restriction**

**Definition**
- infant weight <10th percentile for GA or <2,500 g

**Etiology/Risk Factors**
- maternal causes
  - malnutrition, smoking, drug abuse, alcoholism, cyanotic heart disease, Type 1 DM, SLE, pulmonary insufficiency, previous IUGR
  - maternal-fetal
    - any disease causing placental insufficiency
    - includes gestational HTN, chronic HTN, chronic renal insufficiency, gross placental morphological abnormalities (infarction, hemangiomas)
- fetal causes:
  - TORCH infections, multiple gestation, congenital anomalies

**Clinical Features**
- symmetric/Type I (20%): occurs early in pregnancy
  - head:abdomen ratio may be normal (>1 up to 32 wk; =1 at 32-34 wk; <1 after 34 wk GA)
  - usually associated with congenital anomalies or TORCH infections
- asymmetric/Type II (80%): occurs late in pregnancy
  - brain is spared, therefore head:abdomen ratio increased
  - usually associated with placental insufficiency
  - more favorable prognosis than Type I
  - complications
    - prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, and mental retardation
    - greater risk of perinatal morbidity and mortality

**Investigations**
- SFH measurements at every antepartum visit
- if mother at high risk or SFH lags >2 cm behind GA:
  - anatomy U/S for BPD, head and abdominal circumference, femur length and fetal weight, AFV (decrease associated with IUGR)
  - ± BPP
  - Doppler analysis of umbilical cord blood flow

**Management**
- prevention via risk modification prior to pregnancy is ideal
- modify controllable factors: smoking, alcohol, nutrition and treat maternal illness
- bed rest in LLDP
- serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
- delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if GA >34 wk
- liberal use of C/S since IUGR fetus withstands labour poorly

---

**TORCH**
- Toxoplasmosis
- Others: e.g. syphilis
- Rubella
- CMV
- HSV
- See Table 13, OB20

---

**Differential Diagnosis of Incorrect Uterine Size for Dates**
- Inaccurate dates
- Maternal: diabetes mellitus
- Maternal-fetal: polyhydramnios, oligohydramnios
- Fetal: abnormal karyotype, IUGR, macrosomia, fetal anomaly, abnormal lie, multiple gestation

---

**Monitoring Fetal Growth with U/S**
Done biweekly to show growth beyond the margin of error.
### Macrosomia

**Definition**
- infant weight >90th percentile for a particular GA or >4,000 g

**Etiology/Risk Factors**
- maternal obesity, GDM, past history of macrosomic infant, prolonged gestation, multiparity

**Clinical Features**
- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labour (see Medical Conditions in Pregnancy, OB13)

**Investigations**
- serial SFH
- further investigations if mother at high risk or SFH >2 cm ahead of GA
- U/S predictors
  - polyhydramnios
  - third trimester AC >1.5 cm/wk
  - HC/AC ratio <10th percentile
  - FL/AC ratio <20th percentile

**Management**
- prophylactic C/S is a reasonable option where EFW >5,000 g in non-diabetic woman and EFW >4,500 g in diabetic woman
- no evidence that prophylactic C/S improves outcomes
- early induction of labour is not recommended for non-diabetic mothers
- risks and benefits of early induction (risk of C/S vs. risk of dystocia) must be weighed in diabetic mothers, as current research is unclear

### Polyhydramnios/Oligohydramnios

**Normal Labour and Delivery**

### Definition of Labour

- **true labour**: regular, painful contractions of increasing intensity associated with progressive **dilatation** and **effacement** of cervix and descent of presenting part, or progression of station
  - preterm (>20 but <36+6 wk GA)
  - term (37-41+6 wk GA)
  - post-term (>42 wk GA)
- **false labour**: Braxton-Hicks contractions
  - irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any dilatation, effacement or descent
  - often relieved by rest or sedation

### The Cervix

- **dilatation**: latent phase: 0-3 cm; active phase: 4-10 cm
- **effacement**: thinning of the cervix by percentage or length of cervix (cm)
- **consistency**: firm vs. soft
- **position**: posterior vs. anterior
- **application**: contact between the cervix and presenting part (i.e. well or poorly applied)
- see Bishop score (Table 23, OB36)

### The Fetus

- **fetal lie**: orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, oblique)
- **fetal presentation**
  - fetal part presenting at pelvic outlet
    - breech (complete, frank, footling) (see Figure 9, OB40)
    - cephalic (vertex, face, asynclitic)
    - transverse (shoulder)
    - compound (fetal extremity prolapses along with presenting part)
  - all except vertex are considered malpresentations (see **High Risk Labour and Delivery**, OB38)
- **fetal position**
  - position of presenting part of the fetus relative to the maternal pelvis
    - OA: most common presentation (“normal”) – left OA most common
    - OP: most rotate spontaneously to OA; may cause prolonged second stage of labour
    - OT: leads to arrest of dilatation
    - normally, fetal head enters maternal pelvis and engages in OT position
    - subsequently rotates to OA position (or OP in a small percentage of cases)

---

</table>

**Prognosis**

- 2-5 fold increase in risk of perinatal mortality
- Poorer with early onset
- High mortality related to congenital malformations and pulmonary hypoplasia when diagnosed during T2

**Maternal Triage Assessment**

**ID**: Age, GPA, EDD, GA, GBS, Rh, Ser

**CC**

**HPI**: 4 key questions:

- **Contractions**: Since when, how close (q x min), how long (x s), how painful
- **Bleeding**: Since when, how much (pads), colour (pink mucous = show vs. brownish vs. bright red = clots), pain?, last U/S, trauma/intercourse?
- **Fluid (ROM)**: Since when, large gush vs. trickle, soaked pants?, clear vs. green vs. red?, continuous?
- **FM**: As much as usual?, When last movement?, Kick counts (lie still for 1-2 h, cold juice, feel FM – should have 6 movements in 2 h)

**HxPreg**: Any complications (HTN, GDM, infections), IPS/FTS screening, last ultrasound (BPP score, growth/estimated fetal weight, position), last vaginal exam

**POBHX**: Every previous pregnancy and outcome: Year, SVD/CS/miscarriage/abortion, baby size, length of labour, use of vacuum or forceps, complications

**PMHx, Meds, Allergies, SHx**

**O/E**: Maternal vitals, fetal heart tracing (baseline, variability, presence of accelerations/decelerations), Leopold’s, vaginal exam, U/S

**Reference point for describing fetal position:**

- Occiput for cephalic presentation
- Sacrum for breech presentation
- Mentum for face presentation
• attitude
  ▪ flexion/extension of fetal head relative to shoulders
    • brow presentation: head partially extended (requires C/S)
    • face presentation: head fully extended
      – mentum posterior always requires C/S, mentum anterior will deliver vaginally

• station
  ▪ position of presenting part relative to ischial spines – determined by vaginal exam
    • at ischial spines = station 0 = engaged
    • -5 to -1 cm above ischial spines or
    • +1 to +5 cm below ischial spines
    • alternatively stations can be placed on a scale from -3 to +3

---

Four Stages of Labour

First Stage of Labour
• latent phase
  ▪ uterine contractions typically infrequent and irregular
  ▪ slow cervical dilatation (usually to 3-4 cm) and effacement
• active phase
  ▪ rapid cervical dilatation to full dilatation (nulliparous ~1.2 cm/h, multiparous ~1.5 cm/h)
  ▪ phase of maximum slope on cervical dilatation curve (see Figure 10, OB43)
  ▪ painful, regular contractions q2-3 min, lasting 45-60 s
  ▪ contractions strongest at fundus, weakest at lower segment

Second Stage of Labour
• from full dilatation to delivery of the baby
• mother feels a desire to bear down and push with each contraction
• women may choose a comfortable position that enhances pushing efforts and delivery
  ▪ upright (semi-sitting, squatting) and LLDP are supported in the literature
• progress measured by descent

Third Stage of Labour
• separation and expulsion of the placenta
• can last up to 30 min before intervention indicated
• start oxytocin IV drip or give 10 U IM after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
• routine oxytocin administration in third stage of labour can reduce the risk of PPH by >40%
Fourth Stage of Labour
• first postpartum hour
• monitor vital signs and bleeding
• repair lacerations
• ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
• inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
• 3rd and 4th stages of labour most dangerous to the mother (i.e. hemorrhage)

The Cardinal Movements of the Fetus During Delivery

<table>
<thead>

Figure 8. Cardinal movements of fetus during delivery
Adapted from illustration in Williams Obstetrics, 19th ed

Analgesic and Anesthetic Techniques in Labour and Birth

• pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

Non-pharmacologic Pain Relief Techniques
• reduction of painful stimuli
  • maternal movement, position change, counter-pressure, abdominal compression
  • activation of peripheral sensory receptors
  • superficial heat and cold
  • immersion in water during labour
  • touch and massage, acupuncture and acupressure
  • TENS
  • intradermal injection of sterile water
  • aromatherapy
• enhancement of descending inhibitory pathways
  • attention focusing and distraction
  • hypnosis
  • music and audio analgesia
  • biofeedback

Pharmacologic Methods (see Anesthesia, A22)
• nitrous oxide (e.g. self-administered Entonox®)
• narcotics (usually combined with anti-emetic)
• pudendal nerve block
• perineal infiltration with local anesthetic
• regional anesthesia (epidural block, CSE, spinal)
Fetal Monitoring in Labour

- see online Fetal Heart Rate Tutorial

Vaginal Exam
- membrane status
- cervical effacement (thinning), dilatation, consistency, position, application
- fetal presenting part, position, station
- bony pelvis size and shape
- monitor progress of labour at regular intervals and document in a partogram

Intrapartum Fetal Monitoring
- intermittent fetal auscultation with Doppler device q15-30min for 1 min in first stage active phase following a contraction, q5min during second stage when pushing has begun
- continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labour, and labour which is induced or augmented
  - routine use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate
  - techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
- fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

Electronic FHR Monitoring
- FHR measured by Doppler; contractions measured by tocometer
- described in terms of baseline FHR, variability (short term, long term) and periodicity (accelerations, decelerations)

Baseline FHR
- normal range is 110-160 bpm
- parameter of fetal well-being vs. distress

Variability
- physiologic variability is a normal characteristic of FHR
- variability is measured over a 15 min period and is described as: absent, minimal (less than 6 bpm), moderate (6-25 bpm), marked (greater than 25 bpm)
- normal variability indicates fetal acid-base status is acceptable
- can only be assessed by electronic fetal monitoring (CTG)
- variability decreases intermittently even in healthy fetus
- (see Table 21)

Periodicity
- accelerations: increase of ≥15 bpm lasting ≥15 s, in response to fetal movement or uterine contraction (or ≥10 bpm lasting ≥10 s if <32 wk GA)
- decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability (see Table 20)

- Hypoxia

Continuous CTG as a Form of EFM for Fetal Assessment during Labour
Cochrane DB Syst Rev 2006;3:CD006066

Purpose: To examine the effectiveness of continuous fetal heart monitoring (cardiotocography) during labour on improving health outcomes.

Methods: Systematic review comparing continuous fetal monitoring with no monitoring, intermittent auscultation, and intermittent monitoring.

Results: 12 trials (37,000 women) meeting search criteria were identified, of which 2 trials were high quality. Continuous electronic fetal heart monitoring did not have an effect on overall perinatal death rate compared to intermittent auscultation, with a relative risk (RR) of 0.85, 95% CI 0.59-1.23. Continuous monitoring also led to increased incidence of CS (RR 1.86, 95% CI 1.30 to 2.63, n=18,761, 10 trials) and instrument assisted vaginal delivery (RR 1.2, 95% CI 1.01 to 1.32, n = 18,181, nine trials). These results appeared consistent regardless if pregnancy was high risk, low risk, or preterm.

Conclusion: Continuous fetal cardiotocography does not significantly improve infant mortality or other standards of infant well-being. It increases the incidence of CS and instrument assisted vaginal delivery.

Fetal Scalp Blood Sampling
- indicated when atypical or abnormal fetal heart rate is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns, including unexplained low variability, repetitive late decelerations, complex variable decelerations, fetal cardiac arrhythmias
  - pH ≥7.25: normal, repeat if abnormal FHR persists
  - pH 7.21-7.24: repeat assessment in 30 min or consider delivery if rapid fall since last sample
  - pH ≤7.20: indicates fetal acidosis, delivery is indicated
contraindications
- known or suspected fetal blood dyscrasia (hemophilia, von Willebrand disease)
- active maternal infection (HIV, genital herpes)

### Table 20. Comparison of Decelerations

<td>Accelerations</td>
<td>Accelerations spontaneous or during scalp stimulation</td>
<td>Absent with scalp stimulation</td>
<td>Nearly absent</td>
</tr>
<tr>
<td>Action</td>
<td>EFM may be interrupted for ≤30 min if mother/fetus stable</td>
<td>Further assessment required</td>
<td>Action required: review clinical situation, obtain scalp pH, prepare for possible delivery</td>
</tr>
</tbody>
</table>

Adapted from SOGC guidelines, September 2008
*Previous classification was “reassuring” vs. “non-reassuring”, but distinction is now made between tracings that have some concerning changes but do not require immediate action (atypical) versus those with major concerns requiring immediate intervention (abnormal)

### Approach to the Management of Abnormal FHR

POISON – ER
- Position (LLPD)
- O₂ (100% by mask)
- IV fluids (corrects maternal hypotension)
- Fetal scalp stimulation
- Fetal scalp electrode
- Fetal scalp pH
- Stop Oxygen
- Notify MD

Vaginal Exam to r/o cord prolapse

Rule out fever, dehydration, drug effects, prematurity
- If above fails, consider C/S

### Fetal Oxygenation

- uterine contractions during labour decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
- most fetuses tolerate this reduction in flow and have no adverse effects
- distribution of oxygen to the fetus depends on maternal, uteroplacental and fetal factors
• fetal response to hypoxia/asphyxia
  ▪ decreased movement, tone, and breathing activities
  ▪ redistribution of fetal blood flow
  ▪ increased flow to brain, heart, and adrenals
  ▪ decreased flow to kidneys, lungs, gut, liver and peripheral tissues
  ▪ increase in blood pressure
  ▪ transient fetal bradycardia followed by fetal tachycardia
  ▪ anaerobic metabolism (decreased pH)

Table 22. Factors Affecting Fetal Oxygenation

<table>
<thead>
<tr>
<th>Factor</th>
<th>Mechanism</th>
<th>Example</th>

</tr>
</tbody>
</table>

Induction of Labour

Definition
• artificial initiation of labour before its spontaneous onset for the purpose of delivery of the fetus and placenta

Prerequisites for Labour Induction
• capability for C/S if necessary
• maternal
  ▪ short, thin, soft, anterior cervix with open os (“inducible” or “ripe”)
  ▪ if cervix is not ripe, use prostaglandin vaginal insert (Cervidil®), prostaglandin gel (Prepidil®), or Foley catheter
• fetal
  ▪ normal fetal heart tracing
  ▪ cephalic presentation
  ▪ adequate fetal monitoring available
  ▪ likelihood of success determined by Bishop score
    ▪ cervix considered unfavourable if <6
    ▪ cervix favourable if ≥6
    ▪ score of 9-13 associated with high likelihood of vaginal delivery

Table 23. Bishop Score

<td>-1, 0</td>
<td>+1, +2, +3</td>
</tr>
</tbody>
</table>

Indications
• post-dates pregnancy (generally >41 wk) = most common reason for induction
• maternal factors
  ▪ diabetes mellitus = second most common reason for induction
  ▪ gestational HTN
  ▪ other maternal medical problems, e.g. renal or lung disease
• maternal-fetal factors
  ▪ isoimmunization, PROM, chorioamnionitis, post-term pregnancy

Induction vs. Augmentation
Induction is the artificial initiation of labour.
Augmentation promotes contractions when spontaneous contractions are inadequate.

Induction is indicated when the risk of continuing pregnancy exceeds the risks associated with induced labour and delivery.

Consider the Following before Induction
• Indication for induction
• Contraindications
• GA
• Cervical favourability
• Fetal presentation
• Potential for CPD
• Fetal well-being/FHR
• Membrane status
• fetal factors
  ▪ suspected fetal jeopardy as evidenced by biochemical or biophysical indications
  ▪ fetal demise, IUGR

Risks
• failure to achieve labour and/or vaginal birth
• uterine hyperstimulation and fetal compromise
• maternal side effects to medications
• uterine atony and PPH
• uterine rupture

Contraindications
• maternal
  ▪ prior classical or inverted T-incision or uterine surgery (e.g. myomectomy)
  ▪ unstable maternal condition
  ▪ active maternal genital herpes
  ▪ invasive cervical carcinoma
  ▪ pelvic structure deformities
• maternal-fetal
  ▪ placenta previa or vasa previa
  ▪ cord presentation
• fetal
  ▪ fetal distress, malpresentation, preterm fetus without lung maturity

Induction Methods

CERVICAL RIPENING

Definition
• use of medications or other means to soften, efface and dilate the cervix to increase likelihood of induction success
• ripening of an unfavourable cervix (Bishop score <6) is warranted prior to induction of labour

Methods
• intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
  ▪ recommended dosing interval of prostaglandin gel is every 6 to 12 h up to 3 doses
  ▪ continuous release, can be removed if needed
  ▪ controlled release PGE2
• Foley catheter placement to mechanically dilate the cervix

INDUCTION OF LABOUR

Amniotomy
• artificial rupture of membranes (amniotomy) to stimulate PG synthesis and secretion; may try this as initial measure if cervix is dilated
• few studies address the value of amniotomy alone for induction of labour
• amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (relative risk = 0.03) and had fewer instrumental vaginal deliveries (relative risk = 5.5)

Oxytocin
• oxytocin (Pitocin®): 10 U in 1L NS, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60 min to a max of 36-48 mU/min
  ▪ reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR 0.16)
  ▪ ideal dosing regime of oxytocin is not known
  ▪ current recommendations: use the minimum dose to achieve active labour and increase q30min as needed
  ▪ reassessment should occur once a dose of 20 mU/min is reached
• potential complications
  ▪ hyperstimulation/tetanic contraction (may cause fetal distress or rupture of uterus)
  ▪ uterine muscle fatigue, uterine atony (may result in PPH)
  ▪ vasopressin-like action causing anti-diuresis

Augmentation of Labour
• augmentation of labour is used to promote adequate contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur
• oxytocin (0.5-2 mU/min IV increasing by 1-2 mU/min q20-60 min to a max of 36-48 mU/min)
Preterm Labour

Definition
• labour occurring between 20 and 37 wk gestation

Etiology
• idiopathic (most common)
• maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), genital infection (bacterial vaginosis is associated with a 2-fold increase in relative risk of preterm birth), HTN, DM, chronic illness, mechanical factors, previous obstetric, gynecological and abdominal surgeries, socio-environmental (poor nutrition, smoking, drugs, alcohol, stress)
• maternal-fetal: PPROM (common), polyhydramnios, placenta previa or abruption, placental insufficiency
• fetal: multiple gestation, congenital abnormalities of fetus, fetal hydrops
• uterine: incompetent cervix, excessive enlargement (hydramnios), malformations (leiomyomas, septate uterus)

Epidemiology
• preterm labour complicates about 10% of pregnancies

Risk Factors and Prediction of PTL
• maternal risk scoring using above etiologies fails to identify up to 70% of preterm deliveries and is therefore of limited use
• prior history of spontaneous PTL: most important risk factor
• prior history cervical excisions or mechanical dilatation
• cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk)
• identification of bacterial vaginosis (Rx metronidazole) and ureaplasma urealyticum (Rx erythromycin) infections: routine screening not supported by current data but it is reasonable to screen high risk women
• fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue functioning to maintain integrity of chorionic-decidual interface in asymptomatic women
  • positive if >50 ng/mL
  • in symptomatic women (i.e. preterm contractions), fetal fibronectin is most effectively combined with U/S detecting cervical length
  • if cervical length is not short and fetal fibronectin is negative, preterm labour is highly unlikely

Clinical Features
• regular contractions (2 in 10 min)
• cervix >2 cm dilated or 80% effaced or documented change in cervix

Management
A. Initial
• transfer to appropriate facility if stable
• hydration (NS at 150 mL/h)
• bed rest in LLDP
• sedation (morphine)
• avoid repeated pelvic exams (increased infection risk)
• U/S examination of fetus (GA, BPP, position, placenta location, estimated fetal weight)
• prophylactic antibiotics; controversial but may help delay delivery, important to consider if PPROM

B. Suppression of Labour – Tocolysis
• does not inhibit preterm labour completely, but may buy time to allow for betamethasone valerate (Celestone®) and/or transfer to appropriate centre
• requirements (all must be satisfied)
  • preterm labour
  • live, immature fetus, intact membranes, cervical dilatation of <4 cm
  • absence of maternal or fetal contraindications
• contraindications
  • maternal: bleeding (placenta previa or abruption), maternal disease (hypertension, diabetes, heart disease), preeclampsia or eclampsia, chorioamnionitis
  • fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)
• tocolytic procedure
  • should be used only for <48 h and/or until transfer to an appropriate facility for care of the premature infant

Positive fetal fibronectin in cervicovaginal fluid (>50 ng/mL) at 24 wk gestation predicted spontaneous PTL at <34 wk with sensitivity of 23%, specificity of 97%, PPV of 25%, NPV of 96%.
• agents
  • calcium channel blockers: Nifedipine
    • 20 mg PO loading dose followed by 20 mg PO 90 min later. 20 mg can be continued q3-8h for 72 h or to a max of 180 mg
    • 10 mg PO q20min x 4 doses
  • prostaglandin synthesis inhibitors: Indomethacin
    • 1st line for early preterm labour (<30 wk GA) or polyhydramnios
    • 50-100 mg PO loading dose followed by 25 mg q4-6h
    • Magnesium sulphate was previously used for tocolysis. Currently, its primary use in obstetrics is limited to neuroprotection.

C. Enhancement of Fetal Pulmonary Maturity
• betamethasone valerate (Celestone®) 12 mg IM q24h x 2 or dexamethasone 6 mg IM q12h x 4
• 28-34 wk GA: reduces incidence of RDS
• 24-28 wk GA: reduces severity of RDS, overall mortality and rate of IVH
• specific maternal contraindications: active TB

D. Cervical Cerclage
• definition: placement of cervical sutures at the level of the internal os, usually at the end of the first trimester and removed in the third trimester
• indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)
  • emerging evidence indicates that progesterone suppositories are superior to cerclage in preventing preterm labour late in pregnancy
  • diagnosis of cervical incompetence
    • obstetrical Hx: silent cervical dilation
    • ability of cervix to hold an inflated Foley catheter during a hysterosonogram
  • proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. conization of the cervix, connective tissue disorders)
  • benefit is variable in those with secondary cervical incompetence causing premature ripening of the cervix (e.g. infection, abnormal placentation)

Prognosis
• prematurity is the leading cause of perinatal morbidity and mortality
• 30 wk or 1,500 g (3.3 lb) = 90% survival
• 33 wk or 2,000 g (4.4 lb) = 99% survival
• morbidity due to asphyxia, hypoxia, sepsis, RDS, intraventricular cerebral hemorrhage, thermal instability, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis

Prevention of Preterm Labour
• currently there are no agents approved by Health Canada to arrest preterm labour
• preventative measures: good prenatal care, identify pregnancies at risk, treat silent vaginal infection or UTI, patient education
• transvaginal ultrasound of cervical length is recommended only for high-risk pregnancies

Premature Rupture of Membranes

Definitions
• PROM or amniorrhexis: rupture of membranes prior to labour at any GA
• prolonged ROM: >24 h elapsed between rupture of membranes and onset of labour
• preterm ROM: ROM occurring before 37 wk gestation (associated with PTL)
• PPROM: rupture of membranes before 37 wk AND prior to onset of labour

Risk Factors
• maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STI, UTI), family history of PROM, low socioeconomic class/poor nutrition
• fetal: congenital anomaly, multiple gestation
• other risk factors associated with PTL

Clinical Features
• history of fluid gush or continued leakage

Investigations
• sterile speculum exam (avoid introduction of infection)
  • pooling of fluid in the posterior fornix
  • may observe fluid leaking out of cervix on cough/Valsalva ("cascade")
  • nitrazine (amniotic fluid turns nitrazine paper blue)
  • low specificity as can be positive with blood, urine or semen
• ferning (high salt in amniotic fluid evaporates, looks like ferns under microscope)
• U/S to r/o fetal anomalies, assess GA and BPP

Cerclage for Short Cervix on Ultrasonography in Women With Singleton Gestations and Previous Preterm Birth
Obstet Gynecol 2011;117:663-671

Purpose: To determine if cerclage prevents preterm birth (<35 wk gestation) and perinatal morbidity and mortality among women with previous spontaneous preterm birth, asymptomatic singleton gestation, and short cervical length (<25 mm before 24 wk gestation) on transvaginal ultrasound.

Methods: Meta-analysis of randomized trials identified using searches on MEDLINE, PUBMED, EMBASE and the Cochrane Library.

Results: 5 trials included. Preterm birth was significantly lower among women receiving cerclage versus those not (RR = 0.70, 95% CI: 0.55, 0.88). Cerclage also significantly reduced preterm birth before 24, 28, 32, and 37 wk of gestation. Perinatal mortality and morbidity were significantly lower in the cerclage group (RR = 0.84, 95% CI: 0.45, 0.91).

Conclusions: Cerclage significantly prevents preterm birth and perinatal mortality and morbidity in this specific group of women.
Management
- admit for expectant management and monitor vitals q4h, daily BPP and WBC count
- avoid introducing infection with examinations (do NOT do a bimanual exam)
- cultures (cervix for GC, lower vagina for GBS)
- assess fetal lung maturity by L/S ratio of amniotic fluid
  - consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <32 wk and no evidence of infection
  - consider tocolysis for 48 h to permit administration of steroids if PPROM induces labour
- if not in labour or labour not indicated, consider antibiotics (controversial)
  - studies show broad spectrum coverage increases the time to onset of labour from PROM by 5-7 d with no increase in maternal or neonatal morbidity or mortality
- deliver urgently if evidence of fetal distress and/or chorioamnionitis

Table 24. PROM Management

<table>
<thead>
<tr>
<th>Degree of Prematurity</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;24 wk</td>
<td>Consider termination (poor outcome due to pulmonary hypoplasia)</td>

</tr>
<tr>
<td>34-36 wk</td>
<td>“Grey zone” where risk of death from RDS and neonatal sepsis is the same</td>
</tr>
<tr>
<td>≥37 wk</td>
<td>Induction of labour since the risk of death from sepsis is greater than RDS</td>
</tr>
</tbody>
</table>

Prognosis
- varies with gestational age
- 90% of women with PROM at 28-34 wk GA go into spontaneous labour within 1 wk
- 50% of women with PROM at <26 wk GA go into spontaneous labour within 1 wk
- complications: cord prolapse, intrauterine infection (chorioamnionitis), premature delivery, limb contracture

Breech Presentation

Definition
- fetal buttocks or lower extremity is the presenting part as determined on U/S (see Figure 9)
- complete (10%): flexion at hips and knees
- frank (60%): flexion at hips, extension at knees
- most common type of breech presentation
- most common breech presentation to be delivered vaginally
- footling (30%): may be single or double with extension at hip(s) and knee(s) so that foot is the presenting part

Epidemiology
- occurs in 3-4% of pregnancies at term (25% before 28 wk)

Risk Factors
- maternal: pelvis (contracted), uterus (shape abnormalities, intrauterine tumours, fibroids), extraterine tumours causing compression, grand multiparity
- maternal-fetal: placenta (previa), amniotic fluid (poly/oligohydramnios)
- fetal: prematurity, multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy

Management
- ECV: repositioning of fetus within uterus under U/S guidance
  - overall success rate of 65%
  - criteria: <37 wk, singleton, unengaged presenting part, reactive NST
  - contraindications: previous T3 bleed, prior classical C/S, previous myomectomy, oligohydramnios, PROM, placenta previa, abnormal U/S, suspected IUGR, hypertension, uteroplacental insufficiency, nuchal cord
  - risks: abruption, cord compression
  - method: tocometry, followed by ultrasound guided transabdominal manipulation of fetus with consistent fetal heart monitoring
  - if patient Rh negative, give Rhogam® prior to procedure
  - good prognostic factors (for a successful version)
    - multiparous, good fluid volume, small baby, skilled obstetrician
  - pre- or early labour ultrasound to assess type of breech presentation, fetal growth, estimated weight, attitude of fetal head; if ultrasound unavailable, recommend C/S
  - trial of labour and elective C/S should be presented as options with the risks and benefits outlined; obtain informed consent

Criteria for Vaginal Breech Delivery
- Frank or complete breech, GA ≥36 wk
- EFW 2,500-3,800 g based on clinical and U/S assessment (5.5–8.5 lb)
- Fetal head flexed
- Continuous fetal monitoring
- 2 experienced obstetricians, assistant, and anaesthetist present
- Ability to perform emergency C/S within 30 min if required
• method for vaginal breech delivery:
  ▪ encourage effective maternal pushing efforts
  ▪ at delivery of after-coming head, assistant must apply suprapubic pressure to flex and engage fetal head
  ▪ delivery can be spontaneous or assisted; avoid fetal traction
  ▪ apply fetal manipulation only after spontaneous delivery to level of umbilicus
• C/S recommended if: the breech has not descended to the perineum in the second stage of labour after 2 h, in the absence of active pushing, or if vaginal delivery is not imminent after 1 h of active pushing
• contraindications to vaginal breech delivery:
  ▪ cord presentation
  ▪ clinically inadequate maternal pelvis
  ▪ fetal factors incompatible with vaginal delivery (see OB37)

Prognosis
• regardless of route of delivery, breech infants have lower birth weights and higher rates of perinatal mortality, congenital anomalies, abruption and cord prolapse

Vaginal Birth After Cesarean (VBAC) aka Trial of Labour After Cesarean (TOLAC)
• recommended after previous low transverse incision
• success rate varies with indication for previous C/S (generally 60-80%)
• risk of uterine rupture (<1% with low transverse incision)

Contraindications
• previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
• history of hysterotomy or previous uterine rupture
• multiple gestation
• non-vertex presentation or placenta previa
• inadequate facilities or personnel for emergency C/S

Prolonged Pregnancy

Definition
• pregnancy beyond 42 wk GA

Epidemiology
• 41 wk GA: up to 27%
• 42 wk GA: 4-14%

Etiology
• most cases idiopathic
• anencephalic fetus with no pituitary gland
• placental sulfatase deficiency (X-linked recessive condition in 1/2,000-1/6,000 infants) – rare

Clinical Features
• postmaturity syndrome: 10-20% of post-term pregnancies (fetal weight loss, reduction in subcutaneous fat, scaling, dry skin from placental insufficiency, long thin body, open-eyed, alert and worried look, long nails, palms and soles wrinkled)
• with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries

Management
• GA 40-41 wk: expectant management
  ▪ no evidence to support IOL or C/S unless other risk factors for morbidity are present (see prognosis)
• GA >41 wk: offer IOL if vaginal delivery is not contraindicated
• IOL shown to decrease C/S, fetal heart rate changes, meconium staining, macrosomia and death when compared with expectant management
• GA >41 wk and expectant management elected: serial fetal surveillance
  ▪ fetal movement count by the mother
  ▪ BPP q3-4d
  ▪ If AFI is decreased, labour will be induced
**Prognosis**
- If >41 wk, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
- Morbidity increased with hypertension in pregnancy, DM, abruption, IUGR and multiple gestation

**Intrauterine Fetal Death**

**Definition**
- Fetal death in utero after 20 wk GA

**Epidemiology**
- 1% of pregnancies

**Etiology**
- 50% idiopathic
- 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, APS

**Clinical Features**
- Decreased perception of fetal movement by mother
- SFH and maternal weight not increasing
- Absent fetal heart tones (not diagnostic)
- High MSAFP

**Management**
- Diagnosis: Absent cardiac activity and fetal movement on U/S required for diagnosis
- Determine secondary cause
  - Maternal: HbA1c, Kleihauer-Betke, VDRL, ANA, antibody screens, INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, TORCH screen
  - Fetal: Chromosomes, cord blood, skin biopsy, genetics evaluation, autopsy
  - Placenta: Pathology, bacterial cultures

**Treatment**
- Induction of labour
- Monitor for maternal coagulopathy (10% risk of DIC)
- Parental psychological care as per hospital protocol
- Comprehensive discussion within 3 mo about final investigation and post-mortem results, help make plans for future pregnancies

**Complications of Labour and Delivery**

**Meconium in Amniotic Fluid**

**Epidemiology**
- Present early in labour in 10% of pregnancies
- In general, meconium may be present in up to 25% of all labours; usually NOT associated with poor outcome, but extra care is required at time of delivery to avoid aspiration

**Etiology**
- Likely cord compression ± uterine hypertonus
- May indicate undiagnosed breech
- Increasing meconium during labour may be a sign of fetal distress

**Features**
- Consistency and colour:
  - Light yellow/green or dark green-black in colour.
  - May be watery or thicker

**Treatment**
- Call respiratory therapy, neonatology or pediatrics to delivery room
- Oropharynx suctioning upon head expulsion or immediately after delivery if baby not breathing spontaneously (do NOT stimulate infant before)
- Consider amnioinfusion of ~800 mL of IV NS over 50-80 min during active stage of labour and a maintenance dose of ~3 mL/min until delivery
- Closely monitor FHR for signs of fetal distress

DIC: Generalized Coagulation and Fibrinolysis Leading to Depletion of Coagulation Factors

**Obstetrical Causes**
- Abruption
- Gestational HTN
- Fetal demise
- PPH

**DIC-specific Bloodwork**
- Platelets
- aPTT and PT
- FDP
- Fibrinogen

**Treatment**
- Treat underlying cause
- Supportive
  - Fluids
  - Blood products
  - FFP, platelets, cryoprecipitate
  - Consider anti-coagulation as VTE prophylaxis

Dark green or black meconium is associated with lower APGARS and increased risk of meconium aspiration.
Abnormal Progression of Labour (Dystocia)

**Definition**
- expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labour (see Figure 10)
- during active phase: >4 h of <0.5 cm/h
- during 2nd phase: >1 h with no descent during active pushing

**Etiology**
- **Power** (leading cause): contractions (hypotonic, incoordinate), inadequate maternal expulsive efforts
- **Passenger**: fetal position, attitude, size, anomalies (hydrocephalus)
- **Passage**: pelvic structure (CPD), maternal soft tissue factors (tumours, full bladder or rectum, vaginal septum)
- **Psyche**: hormones released in response to stress may contribute to dystocia. Psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed

**Figure 10. Normal and abnormal courses of the first stage of labour**

**Arrest Disorder (Curve C)**
- arrest of dilatation
  - dilatation progress does not occur for ≥2 h in a patient who has entered the active phase
  - arrest usually occurs at a cervical dilatation of 5-8 cm
- arrest of descent
  - no progress in station for >1 h during second stage
  - should search for factors causing CPD (nearly 50% require C/S)
  - CPD diagnosed if adequate contractions measured by intrauterine pressure catheter (IUPC) with no descent/dilatation for >2 h
  - if CPD ruled out, IV oxytocin and amniotomy can be attempted

**Protraction Disorders (Curve D)**
- protraction of dilatation: slope of cervical dilatation <1.2 cm/h in primigravida or <1.5 cm/h in multigravida
- protraction of descent: a rate of descent of <1.0 cm/h in primigravida or 2.0 cm/h in multigravida
- treatment: oxytocin augmentation if contractions are inadequate ± amniotomy

**Prolonged Latent Phase (Curve E)**
- ≥20 h in primigravida or ≥14 h in multigravida during which labour has not progressed to the active phase
- most often due to false labour (avoid amniotomy for fear of false labour and increased risk of intrauterine infection)
- premature or excessive use of sedation or analgesia may play a role
- careful search for factors of CPD should be made
- management: oxytocin augmentation if diagnosis of labour is certain, otherwise rest ± sedation

**Risks of Dystocia**
- inadequate progression of labour is associated with an increased incidence of:
  - maternal stress
  - maternal infection
  - postpartum hemorrhage
  - need for neonatal resuscitation
Shoulder Dystocia

Definition
- Impaction of anterior shoulder of fetus against symphysis pubis after fetal head has been delivered
- Life threatening emergency

Etiology/Epidemiology
- Incidence 0.15-1.4% of deliveries
- Occurs when breadth of shoulders is greater than biparietal diameter of the head

Risk Factors
- Maternal: obesity, diabetes, multiparity
- Fetal: prolonged gestation, macrosomia
- Labor
  - Prolonged 2nd stage
  - Prolonged deceleration phase (8-10 cm)
  - Instrumental midpelvic delivery

Clinical Features
- “turtle sign”: head delivered but retracts against inferior portion of pubic symphysis
- Complications
  - Chest compression by vagina or cord compression by pelvis can lead to hypoxia
  - Brachial plexus injury (Erb’s palsy: C5-C7; Klumpke’s palsy: C8-T1)
  - 90% resolve within 6 mo
  - Fetal fracture (clavicle, humerus, cervical spine)
  - Maternal perineal injury, may result in PPH

Treatment
- Goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved (see sidebar)
- Other options:
  - Cleidotomy (deliberate fracture of neonatal clavicle)
  - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent C/S
  - Symphysiotomy

Prognosis
- 1% risk of long term disability for infant

Approach to the Management of Shoulder Dystocia
ALARMER
- Apply suprapubic pressure and ask for help
- Legs in full flexion (McRobert’s maneuver)
- Anterior shoulder disimpaction (suprapubic pressure)
- Release posterior shoulder by rotating it anteriorly with hand in the vagina under adequate anesthesia
- Manual corkscrew i.e. rotate the fetus by the posterior shoulder until the anterior shoulder emerges from behind the maternal symphysis
- Episiotomy
- Rollover (on hands and knees)
- *Note that suprapubic pressure and McRoberts maneuver together will resolve 90% of cases

Umbilical Cord Prolapse

Definition
- Descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

Etiology/Epidemiology
- Increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, CPD
- Incidence: 0.17-0.63%

Clinical Features
- Visible or palpable cord
- FHR changes (variable decelerations, bradycardia or both)

Treatment
- Emergency C/S
- O2 to mother, monitor fetal heart
- Alleviate pressure of the presenting part on the cord by placing digit in vagina (maintain this position until C/S)
- Keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
- Position mother in Trendelenburg or knee-to-chest position
- If fetal demise or too premature (<22 wk), allow labour and delivery

Umbilical Cord Accident Causes
- Nuchal cord
  - Type A (looped)
  - Type B (hitched)
- Body loop
- Single artery
- True knot
- Torsion
- Velamentous
- Short cord < 35 cm
- Long cord > 80 cm
Uterine Rupture

Etiology/Epidemiology
- associated with previous uterine scar (in 40% of cases), hyperstimulation with oxytocin, grand multiparity and previous intrauterine manipulation
- generally occurs during labour, but can occur earlier with a classical incision
- 0.5-0.8% incidence, up to 12% with classical incision

Clinical Features
- prolonged fetal bradycardia – most common presentation
- acute onset abdominal pain
- hyper or hypotonic uterine contractions
- vaginal bleed

Risk Factors:
- uterine scarring (i.e. previous uterine surgeries including Cesarean, perforation with D&C)
- excessive uterine stimulation (i.e. protracted labour, oxytocin)
- uterine trauma (i.e. operative equipment, ECV)
- multiparity
- uterine abnormalities

Treatment
- rule out placental abruption
- immediate delivery for fetal survival
- maternal stabilization (may require hysterectomy)

Complications
- maternal mortality 1-10%
- maternal hemorrhage, shock, DIC
- amniotic fluid embolus
- hysterectomy if uncontrollable hemorrhage
- fetal distress, associated with 50% fetal mortality

Amniotic Fluid Embolus

Definition
- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

Etiology/Epidemiology
- rare intrapartum or immediate postpartum complication
- 60-80% maternal mortality rate, accounts for 10% of all maternal deaths
- leading cause of maternal death in induced abortions and miscarriages
- 1/8,000-1/80,000 births

Risk Factors
- placental abruption
- rapid labour
- multiparity
- uterine rupture
- uterine manipulation

Differential Diagnosis
- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruptio, chronic coagulopathy

Clinical Features
- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia) and coagulopathy
- seizure in 10%
- ARDS and left ventricular dysfunction seen in survivors

Management
- supportive measures (high flow O₂, ventilation support, fluid resuscitation, inotropic support, ± intubation), coagulopathy correction
- ICU admission

Maternal Mortality Causes
- Thromboembolism
- Cardiac event
- Suicide
- Sepsis
- Eclectic pregnancy
- Hypertension
- Amniotic-fluid embolism
- Hemorrhage

* In Canada (2005), lifetime risk of maternal death is 1 in 11,000
**Chorioamnionitis**

**Definition**
- infection of the chorion, amnion and amniotic fluid typically due to ascending infection by organisms of normal vaginal flora

**Etiology/Epidemiology**
- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- ascending from vagina
- predominant microorganisms include GBS, Bacteroides and Prevotella species, E. coli and anaerobic Streptococcus

**Risk Factors**
- prolonged ROM, long labour, multiple vaginal exams during labour, internal monitoring
- bacterial vaginosis and other vaginal infections

**Clinical Features**
- maternal fever, maternal or fetal tachycardia, uterine tenderness, foul and purulent cervical discharge

**Investigations**
- CBC: leukocytosis
- amniotic fluid: leukocytes or bacteria

**Treatment**
- IV antibiotics
  - ampicillin (2 g IV q6h) and gentamicin (1.5 mg/kg q8h)
  - anaerobic coverage i.e. clindamycin if C/S
- expedient delivery regardless of gestational age

**Complications**
- bacteremia of mother or fetus, wound infection if C/S, pelvic abscess, infant meningitis

**Operative Obstetrics**

**Operative Vaginal Delivery**

**Definition**
- forceps or vacuum extraction

**Indications**
- fetal
  - atypical or abnormal fetal heart rate tracing
  - consider if second stage is prolonged as this may be due to poor contractions or failure of fetal head to rotate
- maternal
  - need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
  - exhaustion, lack of cooperation and excessive analgesia may impair pushing effort

**Forceps**

**Outlet Forceps Position**
- head visible between labia in between contractions
- sagittal suture in or close to AP diameter
- rotation cannot exceed 45°

**Low Forceps Position**
- presenting part at station +2 or greater
- subdivided based on whether rotation less than or greater than 45 degrees

**Mid Forceps Position**
- presenting part below spines but above station +2
- rarely done

**Types of Forceps**
- Simpson forceps for OA presentations
- Kielland (rotational) forceps when rotation of head to OA is recessing
- Piper forceps for breech
Vacuum Extraction

- traction instrument used as alternative to forceps delivery; aids maternal pushing

Table 25. Advantages and Disadvantages of Forceps versus Vacuum Extraction

<table>
<thead>
<tr>
<th></th>
<th>Forceps</th>
<th>Vacuum Extraction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advantages</td>
<td>Higher overall success rate for vaginal delivery</td>
<td>Easier to apply</td>

</tbody>
</table>

Lacerations

- first degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- second degree: involves fascia and muscles of the perineal body but not the anal sphincter
- third degree: involves the anal sphincter but does not extend through it
- fourth degree: extends through the anal sphincter into the rectal mucosa

Episiotomy

Definition
- incision in the perineal body at the time of delivery
- essentially a controlled second degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernous muscle
  - better healing but increased risk of deep tear
  - mediolateral: incision through bulbocavernous, superficial transverse perineal muscle, and levator ani
  - reduced risk of extensive tear but poorer healing and more pain
  - easier to repair

Indications
- to relieve obstruction of the unyielding perineum
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

Complications
- infection, hematoma, extension into anal musculature or rectal mucosa, fistula formation, incontinence

Cesarean Delivery

Epidemiology
- incidence 20-25%

Indications
- maternal: obstruction, active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery, underlying maternal illness (eclampsia, HELLP syndrome, heart disease)
- maternal-fetal: failure to progress, placental abruption or previa, vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, certain congenital anomalies

- after 3 pulls over 3 contractions with no progress, after 3 pop-offs with no obvious cause
- 20 min and delivery is not imminent
Types of Cesarean Incisions

- skin
  - transverse (aka Pfannensteil)
    - decreased exposure and slower entry
    - improved strength and cosmesis
  - vertical midline
    - rapid peritoneal entry and increased exposure
    - increased dehiscence
- uterine
  - low transverse (most common): in noncontractile segment
    - decreased chance for rupture in subsequent pregnancies
  - low vertical
    - used for very preterm infants, poorly developed maternal lower uterine segment
  - classical (rare): in thick, contractile segment
    - used for transverse lie, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid

Risks/Complications

- anesthesia
- hemorrhage (average blood loss ~1,000 cc)
- infection (UTI, wound, endometritis)
  - single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g)
- thromboembolism
- increased recovery time/hospital stay
- maternal mortality (<0.1%)

Puerperal Complications

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

Postpartum Hemorrhage

Definition

- loss of >500 mL of blood at the time of vaginal delivery, or >1,000 mL with C/S
- early – within first 24 h postpartum
- late – after 24 h but within first 6 wk

Epidemiology

- incidence 5-15%

Etiology (4 Ts)

1. Tone
   - uterine atony
     - most common cause of PPH
     - avoid by giving oxytocin with delivery of the anterior shoulder or placenta
     - occurs within first 24 h
     - due to:
       - labour (prolonged, precipitous, induced, augmented)
       - uterus (infection, over-distention)
       - placenta (abruption, previa)
       - maternal factors (grand multiparity, gestational HTN)
       - halothane anesthesia

2. Tissue
   - retained placental products
   - retained blood clots in an atonic uterus
   - gestational trophoblastic neoplasia

3. Trauma
   - laceration (vagina, cervix, uterus), episiotomy, hematoma (vaginal, vulvar, retroperitoneal), uterine rupture, uterine inversion

4. Thrombin
   - coagulopathy
     - most identified prior to delivery (low platelets increases risk)
     - includes hemophilia, DIC, Aspirin® use, ITP, TTP, vWD (most common)
     - therapeutic anti-coagulation

Common OR Questions

7 layers to dissect
Skin, fatty layer, fascia, muscle separation (rectus abdominis), peritoneum, bladder flap, uterus

Layers of the rectus sheath
Above the arcuate line: external oblique, internal oblique, rectus abdominis
Below the arcuate line: external oblique, transversus abdominis, rectus abdominis

Name of the obliterated umbilical ligament
Urachus

Uterine atony is the most common cause of PPH.

DDx of Early PPH – 4 Ts
Tone (atony)
Tissue (retained placenta, clots)
Trauma (laceration, inversion)
Thrombin (coagulopathy)

DDx of Late PPH
Retained products
± endometritis
Sub-involution of uterus
Investigations
- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of tone, tissue or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7–10 min indicates coagulation problem

Management
- ABCs
- 2 large bore IVs and crystalloids
- CBC, coagulation profile, cross and type 4 units pRBCs
- treat underlying cause

Medical Therapy
- oxytocin 20 U/L NS or RL IV continuous infusion
  - in addition can give 10 U IMM after delivery of the placenta
- methylergonovine maleate (ergotamine) 0.25 mg IM/MM q5min up to 1.25 mg; can be given as IV bolus of 0.125 mg (may exacerbate HTN)
- carboprost (Hemabate®), a synthetic PGF-1α analog 0.25 mg IM/MM q15min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal and hepatic dysfunction)

Local Control
- bimanual compression: elevate the uterus and massage through patient's abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

Surgical Therapy (Intractable PPH)
- D&C (beware of vigorous scraping which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), internal iliac artery (not proven), ovarian artery, or hypogastric artery
- hysterectomy last option with angiographic embolization if post-hysterectomy bleeding

Retained Placenta

Definition
- placenta undelivered after 30 min postpartum

Etiology
- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, placenta percreta)

Risk Factors
- placenta previa, prior C/S, post-pregnancy curettage, prior manual placental removal, uterine infection

Clinical Features
- incomplete placenta removed
- risk of postpartum hemorrhage and infection

Investigations
- explore uterus
- assess degree of blood loss

Management
- 2 large bore IVs, type and screen
- Brant maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL NS into umbilical vein
- manual removal if above fails
- D&C if required
**Uterine Inversion**

**Definition**
- inversion of the uterus through cervix ± vaginal introitus

**Etiology/Epidemiology**
- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous (lax uterine ligaments)
- 1/1500-1/2000 deliveries

**Clinical Features**
- can cause profound vasovagal response with vasodilation and hypovolemic shock
- shock may be disproportionate to maternal blood loss

**Management**
- urgent management essential, call anesthesia
- ABCs: initiate IV crystalloids
- can use tocolytic drug (see Management of Preterm Labour, OB38) or nitroglycerin IV to relax uterus and aid replacement
- replace uterus without removing placenta
- remove placenta manually and withdraw slowly
- IV oxytocin infusion (only after uterus replaced)
- re-explore uterus
- may require GA ± laparotomy

**Postpartum Pyrexia**

**Definition**
- fever >38°C on any 2 of the first 10 d postpartum, except the first day

**Etiology**
- endometritis
- wound infection secondary to C/S
- mastitis/engorgement
- UTE
- atelectasis
- pneumonia

**Investigations**
- detailed history and physical exam, relevant cultures
- for endometritis: blood and genital cultures

**Treatment**
- depends on etiology
  - infection: empiric antibiotics, adjust when sensitivities available
  - endometritis: clindamycin + gentamycin IV
  - mastitis: cefoxaxillin or cefazolin
  - wound infection: cephalaxin
  - DVT: anticoagulants
- prophylaxis against post-C/S endometritis: begin antibiotic immediately after cord clamping and administer only 1-3 doses – cefazolin is most common choice

**ENDOMETRITIS**
- definition: infection of uterine myometrium and parametrium
- clinical features: fever, chills, abdominal pain, uterine tenderness, foul-smelling discharge or lochia
- treatment: depends on infection severity; oral antibiotics if well, IV with hospitalization in moderate to severe cases

**VENOUS THROMBOEMBOLISM**
- see Venous Thromboembolism, OB21
Mastitis

- definition: inflammation of mammary glands
- must r/o inflammatory carcinoma, as indicated
- differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, grey to green), often postmenopausal women

| Table 26. Lactational versus Non-Lactational Mastitis |
|---------------------------------|------------------------|------------------------|
| **Lactational**                  | **Non-Lactational**    |
| Epidemiology                    | Periductal mastitis most common |
|                                 | Mean age 32 yr          |
| Etiology                        | S. aureus               |
|                                 | May be sterile          |
|                                 | May be infected with S. aureus or other anaerobes |
|                                 | Smoking is risk factor  |
|                                 | May be associated with mammary duct ectasia |
| Symptoms                        | Unilateral localized pain |
|                                 | Tenderness              |
|                                 | Erythema                |
| Treatment                       | Heat or ice packs       |
|                                 | Continued nursing/pumping |
|                                 | Antibiotics (dicloxacillin/cephalexin) |
|                                 | (Erythromycin if pen-allergic) |
| Abscess                         | Fluctuant mass          |
|                                 | Purulent nipple discharge |
|                                 | Fever, leukocytosis     |
|                                 | Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&D usually required |
|                                 | If mass does not resolve, FNA to exclude cancer and USS to assess presence of abscess |
|                                 | Treatment includes antibiotics, aspiration or I&D (tends to recur) |
|                                 | May develop mammary duct fistula |
|                                 | A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually S. aureus) |

Postpartum Mood Alterations

POSTPARTUM BLUES
- 85% of new mothers, onset day 3-10; extension of the “normal” hormonal changes and adjustment to a new baby
- self-limited, should resolve by 2 wk
- manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency

POSTPARTUM DEPRESSION
- definition: major depression occurring in a woman within 6 mo of childbirth (see Psychiatry, PS12)
- epidemiology: 10-20%, risk of recurrence 50%
- risk factors
  - personal or family history of depression (including PPD)
  - prenatal depression or anxiety
  - stressful life situation
  - poor support system
  - unwanted pregnancy
  - colicky or sick infant
- clinical features: suspect if the “blues” last beyond 2 wk, or if the symptoms in the first two wk are severe (e.g. extreme disinterest in the baby, suicidal or homicidal/infanticide ideation)
- assessment: Edinburgh Postnatal Depression Scale or other
- treatment: antidepressants, psychotherapy, supportive care, ECT if refractory
- prognosis: interferes with bonding and attachment between mother and baby so it can have long term effects

POSTPARTUM PSYCHOSIS
- definition: onset of psychotic symptoms over 24-72 h within first month postpartum, can present in the context of depression
- epidemiology: rare (0.2%)
Postpartum Care

Postpartum Office Visit at 6 Weeks

Care of Baby
- assess weight, feeding, immunization
- encourage breastfeeding if no contraindications

Care of Mother (The 10 Bs)
- Be careful: do not use douches or tampons for 4-6 wk post-delivery
- Be fit: encourage gradual increases in walking, Kegel exercises
- Birth control: assess for use of contraceptives; breastfeeding is NOT an effective method of birth control (see Gynecology, GY19 for more detail about different contraceptive options postpartum)
- Bladder: assess for urinary incontinence, maintain high fluid intake
- Bleeding: (see Lacerations, OB47), 300 µg of RhIG should be given if Rh+ fetus and Rh− mother or extensive bleeding at delivery
- Blood pressure: especially if gestational HTN
- Blood tests: glucose, CBC (for anemia as sign of hematomas, retained placenta)
- Blues: (see Postpartum Mood Alterations, OB51)
- Bowel: fluids and high-fibre foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, Sitz baths, ice compresses
- Breast and pelvic exam: watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk

Physiological Changes Postpartum
- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
  † should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d for non-lactating women and within 3-6 mo for lactating women
- lochia: normal vaginal discharge postpartum
  † decreases and changes in colour from red (lochia rubra; presence of erythrocytes) → yellow (lochia serosa) → white (lochia alba; residual leukorrhea) over 3-6 wk
  † foul smelling lochia suggests endometritis

Breastfeeding Problems
- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisture cream, topical steroid if needed
- mastitis: treat promptly (see Postpartum Pyrexia, OB50)
- inverted nipples: makes feeding difficult
- maternal medications: may require pediatric consultation (see Breastfeeding and Drugs, OB53)

Bladder Dysfunction
- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management: pelvic floor retraining with Kegel exercises, vaginal cones or pessaries, lifestyle modifications (e.g. limit fluid, caffeine intake)
- surgical management: minimally invasive procedures (tension-free vaginal tape, transobturator tape, midurethral sling) (see Gynecology, GY35)

Puerperal Pain
- “after pains” common in first 3 d due to uterine contractions; encourage simple analgesia
- ice packs can be used on perineum if painful
- encourage regular analgesia and stool softener

The acronym “BUBBLES” for what to ask about when rounding on postpartum care. Modify this for C/S or vaginal delivery

Baby care and breastfeeding (latch, amount)
Uterus – firm or boggy?
Bladder function – Voiding well? Dysuria?
Bowel function – Passing gas or stool? Constipated?
Lochia or discharge – Any blood?
Episiotomy/laceration/incision – Pain controlled?
Symptoms of VTE – Dyspnea? calf pain?
Breastfeeding and Drugs

Table 27. Drug Safety During Breastfeeding

<table>
<thead>
<tr>
<th>Safe During Breastfeeding</th>

Common Medications

Table 28. Common Medications

<table>
<thead>
<tr>
<th>Drug Name (Brand Name)</th>
<th>Dosing Schedule</th>
<th>Indications/Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>betamethasone valerate (Celestone®)</td>
<td>12 mg IM q24h x 2 doses</td>
<td>Enhancement of fetal pulmonary maturity for PTL</td>
</tr>
<tr>
<td>carprofen (Hemabate®)</td>
<td>0.25 mg IM/MM q15min; max 2 mg</td>
<td>Treatment of uterine atony</td>
</tr>
<tr>
<td>cefazolin</td>
<td>2 g IV then 1 g q8h</td>
<td>GBS prophylaxis (penicillin allergic and not at risk for anaphylaxis)</td>
</tr>
<tr>
<td>clindamycin</td>
<td>900 mg IV q8h</td>
<td>GBS prophylaxis (penicillin allergic and at risk for anaphylaxis)</td>
</tr>
<tr>
<td>dexamethasone</td>
<td>6 mg IM q12h x 4 doses</td>
<td>Enhancement of fetal pulmonary maturity for PTL</td>
</tr>
<tr>
<td>dinoprostone (Cervidil®; PGE2 impregnated thread)</td>
<td>10 mg PV (remove after 12h) max of 3 doses</td>
<td>Induction of labour</td>
</tr>
<tr>
<td>doxilamivam</td>
<td>2 tabs qhs + 1 tab qAM + 1 tab qPM max of 8 tabs/d</td>
<td>Each tablet contains 10 mg doxilamivam succinate with vitamin B6</td>
</tr>
<tr>
<td>erythromycin</td>
<td>500 mg IV q6h</td>
<td>GBS prophylaxis (penicillin allergic and at risk for anaphylaxis)</td>
</tr>
<tr>
<td>folic acid</td>
<td>0.4-1 mg PO OD x 1-3 mo; prepregnancy and T1</td>
<td>Prevention of oNTD</td>
</tr>
<tr>
<td>methotrexate</td>
<td>5 mg PO OD with past Hx of NTD</td>
<td>For ectopic pregnancy or medical abortion</td>
</tr>
<tr>
<td>methylfetamine (Ergotamine®)</td>
<td>0.075 mg IM/IMM q5min up to 1.25 mg IV or BOS 0.125 mg</td>
<td>Treatment of uterine atony</td>
</tr>
<tr>
<td>misoprostol (Cytotec®)</td>
<td>80-1000 µg PR x 1 dose 400 µg PO x 1 dose or 800 µg PV x 1 dose, 3 to 7 d after methotrexate</td>
<td>For treatment of PPH</td>
</tr>
<tr>
<td>oxytocin (Pitocin®)</td>
<td>0.5-2.0 mU/min F, or 10 U/L NS incr. by 1-2 mU/min q20-60min max of 36-48 mU/min 10 U IM at delivery of anterior shoulder and of placenta 20 U/L NS or RL IV continuous infusion</td>
<td>Augmentation of labour (also induction of labour)</td>
</tr>
<tr>
<td>Penicillin G</td>
<td>5 million U IV then 2.5 million U IV q4h until delivery</td>
<td>Treatment of uterine atony</td>
</tr>
<tr>
<td>PGE2 gel (Prostin® gel)</td>
<td>0.5 mg PV q6-12h; max of 3 doses</td>
<td>Induction of labour</td>
</tr>
<tr>
<td>Rh IgG (Rhogam®)</td>
<td>300 µg IM x 1 dose</td>
<td>Given to Rh negative women</td>
</tr>
<tr>
<td>misoprostol (Cytotec®) is also indicated to protect against NSAID-induced gastric ulcers in non-pregnant individuals. The use of misoprostol for cytoprotection is contraindicated in pregnancy. Warn female patients of this contraindication.</td>

**Basic Anatomy Review**

**Lateral View**

- Tendon of superior rectus muscle
- Ciliary muscle and body
- Lens
- Conjunctival fornix

**Superior View**

- Anterior chamber iris
- Ciliary muscle and body
- Retina
- Tendon of lateral rectus muscle
- Sclera

**Figure 1. Anatomy of the eye**

**Figure 2. Layers of the retina**
### Differential Diagnoses of Common Presentations

#### Loss of Vision

- **Transient** (seconds to hours)
  - Cornea/Anterior Segment
    - Corneal edema
    - Hyphema
    - Acute angle-closure glaucoma
    - Trauma/foreign body
  - Vitreous/Retina/Optic Nerve
    - Vitreous hemorrhage
    - Retinal detachment
    - Retinal artery/vein occlusion
    - Acute macular lesion
    - Optic neuritis
    - Temporal arteritis
    - Anterior ischemic optic neuropathy (AION)
  - Cortical/Other
    - Occipital infarction/hemorrhage
    - Cortical blindness
    - Functional (non-organic, diagnosis of exclusion)

- **Acute** (seconds to days)
  - Cornea/Anterior Segment
    - Corneal dystrophy/scar/edema
    - Cataract
    - Glaucoma
  - Vitreous/Retina/Optic Nerve
    - Age-related macular degeneration (ARMD)
    - Diabetic retinopathy
    - Retinal vascular insufficiency
    - Compressive optic neuropathy (intracranial mass, orbital mass)
    - Intraocular neoplasm
    - Retinitis pigmentosa
  - Cortical/Other
    - Pituitary adenoma
    - Medication-induced (sildenafil, amiodarone)
    - Nutritional deficiency
    - Papilledema

- **Chronic** (weeks to months)
  - Cornea/Anterior Segment
    - Cataract
    - Refractive error
    - Corneal dystrophy
  - Vitreous/Retina/Optic Nerve
    - ARMD
    - Glaucoma
    - Diabetic retinopathy
  - Cortical/Other
    - Reversible
      - Trauma/foreign body
      - Retinal artery/vein occlusion
      - Retinal detachment
    - Irreversible
      - ARMD
      - Glaucoma
      - Diabetic retinopathy

Note: Anti-VEGF treatment for exudative ARMD and diabetic macular edema may reverse some vision loss.
Red Eye
- lids/orbit/lacrimal system
  - hordeolum/chalazion
  - blepharitis
  - entropion/ectropion
  - foreign body/laceration
  - dacryocystitis/dacryoadenitis
- conjunctiva/sclera
  - subconjunctival hemorrhage
  - conjunctivitis
  - dry eyes
  - pterygium
  - episcleritis/scleritis
  - preseptal/orbital cellulitis
- cornea
  - foreign body (including contact lens)
  - keratitis
  - abrasion, laceration
  - ulcer
- anterior chamber
  - anterior uveitis (iritis, iridocyclitis)
  - acute angle-closure glaucoma
  - hyphema (blood in anterior chamber)
  - hypopyon (pus in anterior chamber)
- other
  - trauma
  - post-operative
  - endophthalmitis

Ocular Pain
- differentiate from eye fatigue (asthenopia)
- herpes zoster prodrome
- trauma/foreign body
- keratitis
- corneal abrasion, corneal ulcer
- acute angle-closure glaucoma
- acute uveitis
- scleritis, episcleritis
- optic neuritis

Floaters
- age-related vitreous syneresis (shrinkage and collapse of vitreous gel)
- posterior vitreous detachment (PVD)
- vitreous hemorrhage
- retinal tear/detachment
- posterior uveitis

Flashes of Light (Photopsia)
- PVD
- retinal tear/detachment
- migraine with aura

Photophobia (Severe Light Sensitivity)
- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis
- meningitis, encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

Diplopia (Double Vision)
- binocular diplopia (occurs with both eyes open, eliminated with occlusion of either eye)
  - strabismus, CN palsy (III, IV, VI) 2° to ischemia, diabetes, tumour, trauma, myasthenia gravis, muscle restriction/entrapment, thyroid ophthalmopathy, internuclear ophthalmoplegia (INO) 2° to multiple sclerosis, brainstem infarct
- monocular diplopia (occurs with one eye open, remains with occlusion of unaffected eye)
  - refractive error, strands of mucus in tear film, keratoconus, cataracts, dislocated lens, peripheral iridotomy

Ocular Problems in the Elderly
- blepharitis
- ptosis
- entropion, ectropion
- dry eyes, epiphora (excessive tearing)
- presbyopia
- cataracts
- glaucoma
- age-related macular degeneration
- retinal artery/vein occlusion
- temporal arteritis (arteritic ischemic optic neuropathy)

Ocular Problems in the Contact Lens Wearer
- superficial punctate keratitis (SPK) from dry eyes
- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- giant papillary conjunctivitis/contact lens allergy
- sterile corneal infiltrates (immunologic)
- infected ulcers (*Pseudomonas, Acanthamoeba*)

Acute Painless Vision Loss
- vitreous hemorrhage
- retinal artery/vein occlusion
- retinal detachment
- anterior ischemic optic neuropathy (AION)
- optic neuritis
- amaurosis fugax

Ocular Emergencies

These require urgent consultation to an ophthalmologist for management

**Sight Threatening**
- lid/globe lacerations
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute angle-closure glaucoma
- CRAO
- intraocular foreign body
- retinal detachment (especially when macula threatened)
- endophthalmitis

**Life Threatening**
- proptosis (r/o cavernous sinus fistula or thrombosis)
- CN III palsy with dilated pupil (intracranial aneurysm or neoplastic lesion)
- papilledema (must r/o intracranial mass lesion)
- orbital cellulitis
- temporal (giant cell) arteritis
- leukocoria: white reflex (absent red reflex, must rule out retinoblastoma)

The Ocular Examination

**Visual Acuity – Distance**
- Snellen Acuity (Figure 5) = testing distance (usually 20 feet or 6 metres)
  - smallest line patient can read on the chart
  - e.g. 20/40 = what the patient can see at 20 feet (numerator), what a “normal” person can see at 40 feet (denominator)
- testing hierarchy for low vision: Snellen acuity (20/x) → counting fingers at a given distance (CF) → hand motion (HM) → light perception with projection (LP with projection) → light perception (LP) → no light perception (NLP)
- legal blindness is BCVA that is ≤20/200 in best eye
- minimum visual requirements to operate a non-commercial automobile in Ontario are: with both eyes open and examined together, 20/50 BCVA

**Visual Acuity – Near**
- use pocket vision chart (Rosenbaum Pocket Vision Screener)
- record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
- conversion to distance VA possible (e.g. immobile patient, no distance chart available)

Example 1
- SC 20/40 -1
- 20/80 +2 → 20/25 PH

Example 2
- CC CF 3’
- HM

Note: RIGHT EYE visual acuity always listed on top.

- V Vision
- SC Without correction
- CC With correction
- 20/40 +1 All except one letter of 20/40
- 20/80 +2 All of 20/80 plus two letters of 20/70
- PH Visual acuity with pinhole correction
- CF Counting fingers
- HM Hand motion

Figure 5. Ophthalmology nomenclature for VA

Normal Infant and Child Visual Acuity
- 6-12 mo: 20/120
- 1-2 yr: 20/80
- 2-4 yr: 20/20

Not every red eye has conjunctivitis.
Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics

- newborns
  - VA cannot be tested
- 3 mo-3 yr (can only assess visual function, not acuity)
  - test each eye for fixation symmetry using an interesting object
  - normal function noted as “CSM” = central, steady, and maintained
- 3 yr until alphabet known
  - pictures or letter cards/charts such as HOTV or Sheridan-Gardner test (children point to optotypes on a provided matching card)
  - tumbling “E” chart

Colour Vision

- test with Ishihara pseudoisochromatic plates
- record number of correctly identified plates presented to each eye, specify incorrect plates
- important for testing optic nerve function (e.g. optic neuritis, chloroquine use, thyroid ophthalmopathy)
- note: red-green colour blindness is sex-linked and occurs in 7-10% of males

VISUAL FIELDS

- test “visual fields by confrontation” (4 quadrants, each eye tested separately) for estimation of visual field loss (Figure 6)
- accurate, quantifiable assessment with automated visual field testing (Humphrey or Goldmann) or Tangent Screen
- use Amsler grid (each eye individually) to test for central or paracentral scotomas (island-like gaps in the vision) in patients with ARMD

PUPILS

- use reduced room illumination with patient focusing on distant object to prevent “near reflex”
- examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
- test for relative afferent pupillary defect (RAPD) with swinging flashlight test
- test pupillary constriction portion of near reflex by bringing object close to patient’s nose
- “normal” pupil testing often noted as PERLA (pupils equal, round, and reactive to light and accommodation)

ANTERIOR CHAMBER DEPTH

- shine light tangentially from temporal side
- if >2/3 of nasal side of iris in shadow → shallow anterior chamber

The van Herick method

- shine thin angled slit beam onto the peripheral cornea of each eye
- estimate depth between the posterior surface of the cornea and the iris as a proportion of corneal thickness
- follow-up with gonioscopy for ratios ≤1/4

Gonioscopy

- allows direct visualization of the angle structures
- angle considered open if trabecular meshwork, scleral spur, and iris processes are visualized
- angle considered narrow (occludable) if only Schwalbe’s line or a small portion of the trabecular meshwork is seen

EXTRAOCULAR MUSCLES

Alignment

- Hirschberg corneal reflex test
  - examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
  - shine light into patient’s eyes from ~30 cm away
  - corneal light reflex should be symmetric and at the same position on each cornea
- strabismus testing as indicated (cover test, cover-uncover test, prism testing) (see Strabismus, OP38)
Movement
- examine movement of eyeball through six cardinal positions of gaze (Figure 8)
- ask patient if diplopia is present in any position of gaze
- observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
- resolving horizontal nystagmus at end-gaze is usually normal
- see sidebar for cranial nerve innervation of extraocular muscles

Diplopia
- major symptom associated with dysfunction of extraocular muscles or abnormalities of the motor nerves innervating these muscles
- must determine whether diplopia is monocular or binocular
- determine whether diplopia was sudden onset (due to an acute event such as ischemia) or gradual (due to progressive process such as tumour or inflammation)
- with myasthenia gravis, diplopia and ptosis usually worsen on prolonged upgaze; can rule out with a Tensilon® test (see Neurology, N32)
- if suspect compressive lesion (most commonly seen with CN III palsy with a blown pupil), need MRI and angiography to rule out aneurysm or tumour
- new-onset diplopia that disappears with occlusion of either eye (binocular diplopia) needs urgent referral while chronic binocular diplopia and monocular diplopia should be referred non-urgently

Diplopia
- major symptom associated with dysfunction of extraocular muscles or abnormalities of the motor nerves innervating these muscles
- must determine whether diplopia is monocular or binocular
- determine whether diplopia was sudden onset (due to an acute event such as ischemia) or gradual (due to progressive process such as tumour or inflammation)
- with myasthenia gravis, diplopia and ptosis usually worsen on prolonged upgaze; can rule out with a Tensilon® test (see Neurology, N32)
- if suspect compressive lesion (most commonly seen with CN III palsy with a blown pupil), need MRI and angiography to rule out aneurysm or tumour
- new-onset diplopia that disappears with occlusion of either eye (binocular diplopia) needs urgent referral while chronic binocular diplopia and monocular diplopia should be referred non-urgently

Figure 8. Diagnostic positions of gaze for isolated primary actions of extraocular muscles

Figure 9. Diplopia

EXTERNAL EXAMINATION
- four Ls
  - lymph nodes (preauricular, submandibular)
  - lids
  - lashes
  - lacrimal system

SLIT-LAMP EXAMINATION
- systematically examine all structures of the anterior segment and anterior vitreous (for structures see Figure 1)
  - when necessary, use:
    - fluorescein dye: stains Bowman’s membrane in de-epithelialized cornea; dye appears green with cobalt blue filtered light
    - Rose Bengal dye: stains devitalized corneal epithelium
  - special lenses (78 or 90 D) used with the slit-lamp allow a binocular, stereoscopic view of the fundus and vitreous

Aqueous Flare
- resembles dust particles in a beam of light
- results from protein leaking from blood vessels
- distinguish from aqueous cells (individual cells in anterior chamber)

Note:
RIGHT EYE drawn on the left,
LEFT EYE drawn on the right
(as if looking at patient’s face).
TONOMETRY
- measurement of intraocular pressure (IOP) (Figure 11)
- normal range is 10-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by:
  - Goldmann applanation tonometry (GAT): gold standard, performed using the slit-lamp with special tip (prism)
  - Tono-Pen®: benefit is portability and use of disposable probe tips. Use when cornea is scarred/asymmetric (GAT inaccurate)
  - air puff (non-contact and least reliable)
- use topical anesthetic for GAT and Tono-Pen®

OPHTHALMOSCOPY/FUNDOSCOPY
- performed with:
  - direct ophthalmoscope (monocular with small field of view, only posterior pole visualized)
  - slit-lamp with 78 or 90 D lens (binocular view, visualization to mid-periphery of retina)
  - indirect ophthalmoscopy with headlamp and 20 or 28 D lens (binocular view, visualization of entire retina to ora serrata/edge of retina)
- best performed with pupils dilated (see Table 11 for list of mydriatics and cycloplegics)
  1. assess red reflex
     - light reflected off the retina produces a “red reflex” when viewed from ~1 foot away
     - anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract)
  2. examine the posterior segment of the eye (Figure 10)
     - vitreous
     - optic disc (colour, C:D ratio, sharpness of disc margin)
     - macula (~2 disc diameters temporal to disc), fovea (foveal light reflex)
     - retinal vessels
     - retinal background
- contraindications to pupillary dilatation
  - shallow anterior chamber – can precipitate acute angle-closure glaucoma
  - iris-supported anterior chamber lens implant
  - potential neurologic abnormality requiring pupil evaluation
  - use caution with cardiovascular disease – mydriatics may cause tachycardia

REFRACITION
- two techniques used
  - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
  - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
- a typical lens prescription would contain:
  - sphere power in D (measurement of refractive power of lens, equal to reciprocal of focal length in meters)
  - cylinder power in D to correct astigmatism (always positive value)
  - axis of cylinder in degrees
  - “add” (bifocal/progressive reading lens) for presbyopes
    - e.g. -1.50 + 1.00 x 120 degrees, add +2.00

REFRACTIVE EYE SURGERY
- permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
- used for correction of myopia, hyperopia, and astigmatism
- common types include PRK and LASIK (see Surgical Ophthalmology, OP44)
- potential risks/side-effects: infection, under/overcorrection, decreased night vision (nyctalopia), corneal haze, dry eyes, regression, complete sever of corneal flap (LASIK only)

<td></td>
<td>Light rays from distant object focus behind retina</td>
<td>“Nearsightedness”</td>
<td>When symptomatic, correct with positive diopter/convex/“plus” lenses to converge light rays</td>
</tr>
<tr>
<td></td>
<td>May be developmental or due to any etiology that shortens globe</td>
<td>May develop accommodative esotropia (see Strabismus; OP38)</td>
<td>Hyperopia corrected with positive converging lens</td>
</tr>
<tr>
<td><strong>Astigmatism</strong></td>
<td>Light rays not refracted uniformly in all meridians due to non-spherical surface of cornea or non-spherical lens (e.g. football-shaped)</td>
<td>Affects approximately 30% of population, with prevalence increasing with age</td>
<td>Correct with cylindrical lens (if regular), try contact lens (if irregular)</td>
</tr>
<tr>
<td></td>
<td>Two types:</td>
<td>Mild astigmatism unnoticeable</td>
<td>Refractive eye surgery</td>
</tr>
<tr>
<td></td>
<td>Regular—curvature uniformly different in meridians at right angles to each other</td>
<td>Higher amounts of astigmatism may cause blurring vision, squinting, asthenopia, or headaches</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Irregular—distorted cornea caused by injury, keratoconus (cone-shaped cornea), corneal scar, or severe dry eye</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Presbyopia</strong></td>
<td>Normal aging process (&gt;40 yr)</td>
<td>If initially emmetropic, person begins to hold reading material farther away, but distance vision remains unaffected</td>
<td>Correct with positive diopter/convex/“plus” lenses for reading</td>
</tr>
<tr>
<td></td>
<td>Hardening/reduced deformability of lens results in decreased accommodative ability</td>
<td>If initially myopic, person removes distance glasses to read</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Accommodative power is 14D at age 10, diminishes to 3.5D by age 40</td>
<td>If initially hyperopic, symptoms of presbyopia occur earlier</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Near images cannot be focused onto the retina (focus is behind the retina as in hyperopia)</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Anisometropia</strong></td>
<td>Difference in refractive errors between eyes</td>
<td></td>
<td>Second most common cause of amblyopia in children</td>

### Imaging Modalities

- **Adaptive optics scanning laser ophthalmology** – optical coherence tomography (SLO-OCT)
  - combines the surface detail of confocal ophthalmoscopy with the internal detail of OCT
  - allows 3D OCT images, volume and area maps, and retinal thickness maps, at the resolution of living rods and cones
  - can visualize photoreceptors, nerve fibres and blood cells in retinal capillaries
- **CT, MRI**
  - orbital imaging, particularly in orbital trauma and neuro-ophthalmology
- **Fluorescein angiography**
  - non-invasive evaluation of vascular pattern of the fundus
  - commonly used in ARMD, DR, retinal vascular diseases
- **Indocyanine green angiography**
  - uses infra-red light and intravenous ICG dye for imaging of choroidal structure
  - particularly useful to detect polypoidal vasculopathy (variant of ARMD) more commonly present among Asian patients
• Heidelberg retinal tomograph (HRT)
  ▪ confocal scanning laser tomography of retinal nerve head and surrounding nerve fibre layer
  ▪ used to assess extent of structural glaucomatous changes
• optical coherence tomography (OCT)
  ▪ non-invasive, cross-sectional, high-resolution imaging of vitreous, retinal layers, optic nerve
  ▪ commonly used to assess macular edema/holes/cysts, ARMD progression, epi-retinal membrane, retinal detachment (RD)
• anterior segment optical coherence tomography (AS-OCT)
  ▪ non-invasive, cross-sectional, high-resolution imaging of cornea, aqueous, iris and lens
• perimetry
  ▪ quantitative evaluation of visual fields, used to screen for scotomas and monitor progression
    (e.g. in glaucoma)
• ultrasonography
  ▪ evaluation of orbit in real-time. A-scans (one-dimensional), B-scans (two-dimensional), and Doppler are all used (e.g. large RDs, foreign bodies, monitoring intraocular tumours)

### The Orbit

#### Globe Displacement

#### Preseptal Cellulitis

• infection of soft tissue anterior to orbital septum

**Etiology**
• usually follows periorbital trauma or dermal infection

**Clinical Features** (Table 4)

**Treatment**
• systemic antibiotics (suspect *H. influenzae* in children; *S. aureus* or *Streptococcus* in adults)
  ▪ e.g. amoxicillin-clavulanic acid
  ▪ if severe or child <1 yr, treat as orbital cellulitis

#### Orbital Cellulitis

• OCULAR and MEDICAL EMERGENCY
• inflammation of orbital contents posterior to orbital septum
• common in children, elderly, and immunocompromised

**Etiology**
• usually 2° to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

**Clinical Features** (Table 4)

**Treatment**
• admit, blood cultures x2, orbital CT, IV antibiotics (ceftriaxone + vancomycin) for 1 wk
• surgical drainage of abscess with close follow-up, especially in children

---

**Periorbital and Orbital Cellulitis Before and After the Advent of Haemophilus influenzae type B Vaccination**

*Ophthalmol 2000;107:1450-1453*

**Study:** Retrospective case series.

**Patients:** 315 pediatric inpatients in Massachusetts with a discharge diagnosis of periorbital or orbital cellulitis.

**Results:** Prior to the introduction of the Hib vaccine, 11.7% of cases were culture positive for Hib. After the vaccination program was initiated, the case rate dropped to 3.5% (P=0.028). All cases of orbital cellulitis were associated with sinusitis, and cases of periorbital cellulitis were most commonly associated with upper respiratory tract infections or sinusitis.
Complications
• optic nerve inflammation, cavernous sinus thrombosis, meningitis and brain abscess with possible loss of vision, death

Lacrimal Apparatus
• tear film made up of three layers
  ▪ outer oily layer (reduces evaporation): secreted by the Meibomian glands
  ▪ middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
  ▪ inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells
• tears drain from the eyes through the upper and lower lacrimal puncta → superior and inferior canaliculi → lacrimal sac → nasolacrimal duct → nasal cavity behind inferior concha (Figure 3)

Dry Eye Syndrome (Keratoconjunctivitis Sicca)

Etiology
• aqueous-deficient (lacrimal pathology)
  ▪ Sjögren Syndrome (autoimmune etiology e.g. rheumatoid arthritis, SLE)
  ▪ non-Sjögren Syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy; anticholinergics, antihistamines, diuretics, β-blockers)
• evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
  ▪ Meibomian gland dysfunction (posterior blepharitis)
  ▪ vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
  ▪ eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
  ▪ preserved topical ocular medications
  ▪ contact lenses, allergic conjunctivitis
• overlap of mixed etiologies common

Clinical Features
• dry eyes, red eyes, foreign body sensation, blurred vision, tearing
• slit-lamp exam: decreased tear meniscus, decreased tear break up time (normally should be 10 s), SPK
• surface damage observed with fluorescein/Rose Bengal staining
• decreased distance in Schirmer’s test

Complications
• erosions and scarring of cornea

Treatment
• medical: preservative-free artificial tears up to q1h and ointment at bedtime (preservative toxicity becomes significant if used more than q1h PRN)
  ▪ for severe cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) can be used
• procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
• treat underlying cause

Long term use of artificial tears with preservatives should be avoided when treating dry eyes.
**Epiphora (Excessive Tearing)**

**Etiology**
- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacryocystitis)
- paradoxical gustatory lacrimation reflex (crocodile tears)

**Investigations**
- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

**Treatment**
- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy (see Surgical Ophthalmology, OP44) – forming a new connection between the lacrimal sac and the nasal cavity

**Dacryocystitis**
- acute or chronic infection of the lacrimal sac
- most commonly due to obstruction of the nasolacrimal duct
- commonly associated with *S. aureus*, *S. pneumoniae*, *Pseudomonas* species

**Clinical Features**
- pain, swelling, redness over lacrimal sac at medial canthus
- epiphora, crusting, ± fever
- digital pressure on the lacrimal sac may extrude pus through the punctum
- in the chronic form, epiphora may be the only symptom

**Treatment**
- warm compresses, nasal decongestants, systemic and topical antibiotics
- if chronic, obtain cultures by aspiration
- once infection resolves, consider dacryocystorhinostomy (see Surgical Ophthalmology, OP44)

**Dacryoadenitis**
- inflammation of the lacrimal gland (outer third of upper eyelid)
- acute causes: *S. aureus*, mumps, EBV, herpes zoster, *N. gonorrhoeae*
- chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, thyroid ophthalmopathy

**Clinical Features**
- pain, swelling, tearing, discharge, redness of the outer region of the upper eyelid
- chronic form is more common and may present as painless enlargement of the lacrimal gland

**Treatment**
- supportive: warm compresses, oral NSAIDs
- systemic antibiotics if bacterial cause
- if chronic, treat underlying disorder

**Lids and Lashes**

**Lid Swelling**

**Etiology**
- commonly due to allergy, with shriveling of skin between episodes
- dependent edema on awakening (e.g. CHF, renal or hepatic failure)
- orbital venous congestion due to mass or cavernous sinus fistula
- dermatochalasis (loose skin due to aging or heredity)
- lid cellulitis, thyroid disease (e.g. myxedema), trauma, chemosis
Ptosis

- drooping of upper eyelid

Etiology

- aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
  - associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
- mechanical
  - incomplete opening of eyelid due to mass or scarring
- neuromuscular
  - myasthenia gravis (neuromuscular palsy), myotonic dystrophy
  - CN III palsy
  - Horner’s syndrome (see Constricted Pupil, Horner’s Syndrome, OP32)
- congenital
- pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)

Treatment

- surgery

Trichiasis

- eyelashes turned inwards
- may result from chronic inflammatory lid diseases (e.g. blepharitis), Stevens-Johnson syndrome, trauma, burns
- patient complains of red eye, foreign body sensation, tearing
- may result in corneal ulceration and scarring

Treatment

- topical lubrication, eyelash plucking, electrolysis, cryotherapy

Entropion

- lid margin turns in towards globe causing tearing, foreign body sensation, and red eye
- most commonly affects lower lid
- may cause abrasions with 2nd corneal scarring

Etiology

- involutional (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

Treatment

- lubricants, evert lid with tape, surgery

Ectropion

- lid margin turns outward from globe causing tearing and possibly exposure keratitis

Etiology

- involutional (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, surgery)
- mechanical (lid edema, tumour, herniated fat)
- congenital

Treatment

- topical lubrication, surgery

Hordeolum (Stye)

- acute inflammation of eyelid gland: either Meibomian glands (internal lid) or glands of Zeis (modified sweat gland) or Moll (modified sebaceous gland in external lid)
- infectious agent is usually S. aureus
- painful, red swelling of lid

Treatment

- warm compresses, lid care, gentle massage
- topical antibiotics (e.g. erythromycin ointment bid)
- usually resolves in 2-5 d
**Chalazion**

- chronic granulomatous inflammation of Meibomian gland often preceded by an internal hordeolum
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell adenoma, Meibomian gland carcinoma

**Treatment**

- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

---

**Blepharitis**

- inflammation of lid margins

**Etiology**

- two main types
  - staphylococcal (S. aureus): ulcerative, dry scales
  - seborrheic: no ulcers, greasy scales

**Clinical Features**

- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids ("toothpaste sign")

**Complications**

- recurrent chalazia
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

**Treatment**

- warm compresses and lid scrubs with diluted "baby shampoo"
- topical or systemic antibiotics as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids

---

**Xanthelasma**

- eyelid xanthoma (lipid deposits in dermis of lids)
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (approximately 50% of patients)
- common in the elderly, more concerning in the young

**Treatment**

- excision for cosmesis only, commonly recurs

---

**Conjunctiva**

- thin, vascular mucous membrane/epithelium
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

---

**Pinguecula**

- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea
- associated with sun and wind exposure, aging
- common, benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops
**Pterygium**
- fibrovascular triangular encroachment of epithelial tissue onto the cornea, usually nasally
- may induce astigmatism, decrease vision
- excision for chronic inflammation, threat to visual axis, cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after excision, lower recurrence with conjunctival autograft (5%)

**Subconjunctival Hemorrhage**
- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, hypertension
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- if recurrent, consider medical/hematologic work-up

**Conjunctivitis**

**Etiology**
- infectious
  - bacterial, viral, chlamydial, fungal, parasitic
- non-infectious
  - allergic: atopic, seasonal, giant papillary conjunctivitis (contact lens wearers)
  - toxic: irritants, dust, smoke, irradiation
  - 2nd to another disorder: dacryocystitis, dacryoadenitis, cellulitis, Kawasaki's disease

**Clinical Features**
- red eye (conjunctival injection often with limbal pallor), chemosis, subepithelial infiltrates
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, lid edema
- preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

**ALLERGIC CONJUNCTIVITIS**

**Atopic**
- associated with rhinitis, asthma, dermatitis, hay fever
- small papillae, chemosis, thickened and erythematous lids, corneal neovascularization
- seasonal (pollen, grasses, plant allergens)
- treatment: cool compresses, antihistamine, mast cell stabilizer (e.g. ketotifen, olopatadine)

**Giant Papillary Conjunctivitis**
- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva
- treatment: clean, change or discontinue use of contact lens

**Vernal Conjunctivitis**
- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal ulcers and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves
- treatment: consider topical steroid, topical cyclosporine (by ophthalmologist)

**VIRAL CONJUNCTIVITIS**
- serous discharge, lid edema, follicles
- subepithelial corneal infiltrates
- may be associated with rhinorrhea
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye
- mainly due to adenovirus – highly contagious for up to 12 d

**Treatment**
- cool compresses, topical lubrication
- usually self-limiting (7-12 d)
- proper hygiene is very important
**BACTERIAL CONJUNCTIVITIS**
- purulent discharge, lid swelling, papillae, conjunctival injection, chemosis
- common agents include *S. aureus, S. pneumoniae, H. influenzae* and *M. catarrhalis*
- in neonates or if sexually active must consider *N. gonorrhoeae* (invades cornea to cause keratitis)
- *Chlamydia trachomatis* is the most common cause in neonates (see *Chlamydial Conjunctivitis*, below)

**Treatment**
- topical broad-spectrum antibiotic
- systemic antibiotics if indicated, especially in neonates and children
- usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment

**CHLAMYDIAL CONJUNCTIVITIS**
- caused by *Chlamydia trachomatis*
- affects neonates (ophthalmia neonatorum) on day 3-5, sexually active individuals
- causes trachoma and inclusion conjunctivitis

**Trachoma**
- leading infectious cause of blindness in the world
- severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
- initially, follicles on superior palpebral conjunctiva
- treatment: topical and systemic tetracycline

**Inclusion Conjunctivitis**
- chronic conjunctivitis with follicles and subepithelial infiltrates
- most common cause of conjunctivitis in newborns
- prevention: topical erythromycin at birth
- treatment: topical and systemic tetracycline, doxycycline or erythromycin

**Sclera**
- white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
- continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
- episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

**Episcleritis**
- immunologically mediated inflammation of episclera
- 1/3 bilateral; simple (80%) or nodular (20%)
- more frequent in women than men (3:1)

**Etiology**
- mostly idiopathic
- in 1/3 of cases, associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, syphilis), inflammatory bowel disease, rosacea, atopy

**Clinical Features**
- usually asymptomatic; may have discomfort, heat sensation, red eye (often interpalpebral), rarely pain
- sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
- blanches with topical phenylephrine (constricts superficial conjunctival vessels)

**Treatment**
- generally self-limited, recurrent in 2/3 of cases
- topical steroid for 3-5 d if painful (prescribed and monitored by ophthalmologist)

**Scleritis**
- usually bilateral: diffuse, nodular, or necrotizing
- anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
- posterior scleritis: rapidly progressive blindness, may cause exudative RD
- more common in women and elderly

---

**Antibiotics versus Placebo for Acute Bacterial Conjunctivitis**
Cochrane DB Syst Rev 2006;2:CD001211

**Study:** Cochrane systemic review and meta-analysis of 5 heterogeneous trials investigating the efficacy of topical antibiotic treatment for bacterial conjunctivitis.

**Patients:** 1034 participants randomized to topical antibiotic treatment or placebo.

**Results:** Topical antibiotics are beneficial in improving early (days 2 to 5) clinical and microbiological remission rates, with respective risk ratios (RR) of 1.24 and 1.77, respectively. Later (days 6 to 10) cure rates are lower than earlier values, with a clinical RR of 1.11 and a microbiological RR of 1.56. Most cases would, however, clinically resolve spontaneously on days 2-5 with placebo treatment only (85%). There were no reported serious outcomes in either group.

**Conclusion:** Topical antibiotic treatment of acute bacterial conjunctivitis is associated with a significantly improved rate of early clinical and microbiological remission, although most cases are self-limiting, and serious sight-threatening complications are rare.
Etiology
- may be a manifestation of systemic disease
- collagen vascular disease, e.g. SLE, rheumatoid arthritis, ankylosing spondylitis
- granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
- metabolic, e.g. gout, thyrotoxicosis
- infectious, e.g. S. aureus, S. pneumoniae, P. aeruginosa, herpes zoster
- chemical or physical agents (e.g. thermal, alkali, or acid burns)
- idiopathic

Clinical Features
- severe pain, photophobia, red eye, decreased vision
- pain is best indicator of disease progression
- inflammation of scleral, episcleral, and conjunctival vessels
- may have anterior chamber cells and flare, corneal infiltrate, scleral thinning
- sclera may have a blue hue (best seen in natural light), due to rearranged scleral fibres
- scleral edema or thinning
- failure to blanch with topical phenylephrine

Treatment
- systemic NSAID or steroid (topical steroids are not effective)
- treat underlying etiology

Cornea

- function
  - transmission of light
  - refraction of light (2/3 of total refractive power of eye)
  - barrier against infection, foreign bodies
- transparency due to avascularity, uniform structure and deturgescence (relative dehydration)
- 5 layers (anterior to posterior): epithelium, Bowman’s membrane, stroma, Descemet’s membrane, endothelium (dehydrates the cornea; dysfunction leads to corneal edema)
- extensive sensory fibre network (V1 distribution); therefore abrasions and inflammation (keratitis) are very painful

Foreign Body
- foreign material in or on cornea
- may have associated rust ring if metallic
- patients may note tearing, photophobia, foreign body sensation, red eye
- signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, anterior chamber cells/flare

Complications
- abrasion, infection, scarring, rust ring, 2° iritis

Treatment
- remove under magnification using local anesthetic and sterile needle or refer to ophthalmology (depending on depth and location)
- treat as per corneal abrasion

Corneal Abrasion

- epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

Clinical Features (Table 5)
- pain, redness, tearing, photophobia, foreign body sensation
- de-epithelialized area stains with fluorescein dye
- pain relieved with topical anesthetic

Complications
- infection, ulceration, recurrent erosion, 2° iritis

Treatment
- topical antibiotic (drops or ointment)
- consider topical NSAID, cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch
- most abrasions clear spontaneously within 24-48 h
Recurrent Erosions

- recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
- usually occurs upon awakening
- associated with improper adherence of epithelial cells to the underlying basement membrane

Etiology

- previous traumatic corneal abrasion
- corneal dystrophy
- idiopathic

Treatment

- as for corneal abrasion until re-epithelialization occurs
- topical hypertonic saline ointment at bedtime for 3 mo, topical lubrication
- bandage contact lens, anterior stromal puncture or phototherapeutic keratectomy for chronic recurrences

Corneal Ulcer

Etiology

- local necrosis of corneal tissue due to infection
- infection is usually bacterial, rarely viral, fungal or protozoan (Acanthamoeba)
- 2° to corneal exposure, abrasion, foreign body, contact lens use (50% of ulcers)
- also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

Clinical Features

- pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
- corneal opacity that necroses and forms an excavated ulcer with infiltrative base
- overlying corneal epithelial defect that stains with fluorescein
- may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
- bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

Complications

- decreased vision, corneal perforation, iritis, endophthalmitis

Investigations

- Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect penetrating lesions. Any aqueous leakage will change dark orange dye to bright yellow-green at site of wound

Treatment

- urgent referral to ophthalmology
- culture prior to treatment
- topical antibiotics every hour
- must treat vigorously to avoid complications

Herpes Simplex Keratitis

- usually HSV type 1 (90% of population are carriers)
- may be triggered by stress, fever, sun exposure, immunosuppression

Clinical Features

- pain, tearing, foreign body sensation, red eye, may have decreased vision, eyelid edema
- corneal hypoesthesia
- dendritic (thin and branching) lesion in epithelium that stains with fluorescein

Antiviral Treatment and other Therapeutic Interventions for Herpes Simplex Virus Epithelial Keratitis

Cochrane DB Syst Rev 2010;12:CD002898

Rates of corneal re-epithelialization after acute HSV corneal epithelial keratitis are similar after treatment with trifluridine or acyclovir, and significantly better than after treatment with idoxuridine or vidarabine. Brivudine and ganciclovir are not inferior to acyclovir. Combining an antiviral agent with Interferon or corneal epithelial debridement did not improve outcomes overall, but did hasten corneal healing. Debridement with concomitant antiviral treatment was more effective than debridement alone.

Patching for corneal abrasion.

Cochrane DB Syst Rev 2006;2:CD004764

Patching is not indicated for simple corneal abrasions, measuring less than 10 mm. There is no improvement in healing rates on days 1-3, no changes in reported pain and no difference in the use of antibiotics between the patch and non-patch groups.

Figure 14. Corneal abrasion vs. ulcer

Abrasion vs. Ulcer on Slit Lamp

An abrasion appears clear while an ulcer is more opaque.

Figure 14. Corneal abrasion vs. ulcer
Complications
- corneal scarring (can lead to loss of vision)
- chronic interstitial keratitis due to penetration of virus into stroma
- 2° iritis, 2° glaucoma

Treatment
- topical antiviral such as trifluridine, consider systemic antiviral such as acyclovir
- dendritic debridement
- NO STEROIDS initially – may exacerbate condition
- ophthalmologist must exercise caution if adding topical steroids for chronic keratitis or iritis

Herpes Zoster
- dermatitis of the forehead (CN V1 territory) may involve globe
- Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then eye will be involved in approximately 75% of cases
- if no nasal involvement, eye is involved in 1/3 of patients

Clinical Features
- pain, tearing, photophobia, red eye
- corneal edema, pseudodendrite, superficial punctate keratitis
- corneal hypoesthesia

Complications
- corneal keratitis, ulceration, perforation and scarring
- 2° iritis, 2° glaucoma, cataract
- muscle palsies (rare) due to CNS involvement
- occasionally severe post-herpetic neuralgia

Treatment
- oral antiviral (acyclovir, valcyclovir, or famciclovir) immediately
- topical steroids, cycloplegia as indicated for keratitis, iritis
- erythromycin ointment if conjunctival involvement

Keratoconus
- bilateral paracentral thinning and bulging (ectasia) of the cornea to form a conical shape
- usually sporadic, but associated with Down's syndrome, atopy, contact lens use (theorized to be related to chronic vigorous eye rubbing)
- associated with breaks in Descemet's and Bowman's membrane
- results in irregular astigmatism, scarring, stromal edema

Treatment
- attempt correction with spectacles or contact lens
- cross-linking treatment may halt or slow disease progression
- intrastromal corneal ring segments can help flatten the corneal cone
- penetrating keratoplasty (corneal transplant) 90% successful
- post-operative complications: endophthalmitis, graft rejection, graft failure, graft dehiscence

Arcus Senilis
- hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
- common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
- may be associated with hypercholesterolemia if age <40 yr, check lipid profile
- no associated visual symptoms, no complications, no treatment necessary

Kayser-Fleischer Ring
- brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
- due to deposition of copper pigment in Descemet's membrane
- associated with Wilson's disease
- no associated symptoms or complications of ring
- treat underlying disease
The Uveal Tract

- uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- vascularized, pigmented middle layer of the eye, between the sclera and the retina

Uveitis

- uveal inflammation which may involve one or all three parts of the tract
- idiopathic or associated with autoimmune, infectious, granulomatous, malignant causes
- should be managed by an optometrist or ophthalmologist
- anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis or panuveitis based on primary site of inflammation

Table 6. Anatomic Classification of Uveitis

</tbody>
</table>

Clinical Features

- Photophobia (due to reactive spasm of inflamed iris muscle), ocular pain, tenderness of the globe, brow ache (ciliary muscle spasm), decreased VA (in severe cases with hydropopy), lacrimation
- Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle)
- Anterior chamber “cells” (WBC in anterior chamber), decreased VA, episcleral injection, keratic precipitates, corneal neovascularization
- Iris typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis, or iritis from herpes simplex and zoster may cause an inflammatory glaucoma (trabeclitis)
- Insidious onset of blurred vision, accompanied by vitreous floaters
- Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric
- Associated with anterior uveitis, most severe cases of 2° intermediate uveitis
- Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells)
- Posterior segment ‘snowbank’ = grey-white fibrovascular plaque at the pars plana
- Painless as choroid has no sensory innervation
- Often no conjunctival or scleral injection present
- Decreased VA
- Floaters (debris and inflammatory cells)
- Vitreous cells and opacities
- Hypopyon formation

Complications

- Inflammatory glaucoma
- Posterior synechiae
  - Adhesions of posterior iris to anterior lens capsule
  - Indicated by an irregularly shaped pupil
  - If occurs 360° entraps aqueous in posterior chamber, iris bows forward “iris bombé” → angle closure glaucoma
- Peripheral anterior synechiae (rare); adhesions of iris to cornea → secondary angle closure glaucoma
- Cataracts
- Band keratopathy (with chronic iritis)
- Superficial corneal calcification keratopathy
- Macular edema with chronic iritis
- Cystoid macular edema (30% of cases), cataract, and glaucoma
- Macular edema
- Vitritis
- Neovascularization
- Visual field loss/scotoma

Treatment

- Mydriatics: dilate pupil to prevent formation of posterior synechiae and to decrease pain from ciliary spasm
- Steroids: topical, sub-tenon or systemic
- Systemic analgesia
- Extensive medical workup may be indicated to rule out 2° causes
- Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents
- Vitrectomy, cryotherapy or laser photoagulation to the “snowbank”
- Steroids: sub-tenon, intravitreal or systemic if indicated (e.g. threat of vision loss)
Lens

- consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

Cataracts

- any opacity of the lens, regardless of etiology
- most common cause of reversible blindness worldwide
- types: nuclear sclerosis, cortical, posterior subcapsular

Etiology

- acquired
  - age-related (over 90% of all cataracts)
  - cataract associated with systemic disease (may have juvenile onset)
    - diabetes mellitus
    - metabolic disorders (e.g. Wilson's disease, galactosemia, homocystinuria)
    - hypocalcemia
    - traumatic (may be rosette shaped)
    - intraocular inflammation (e.g. uveitis)
    - toxic (steroids, phenothiazines)
    - radiation
  - congenital
    - high myopia
    - present with altered red reflex or leukocoria
    - treat promptly to prevent amblyopia

Clinical Features

- gradual, painless, progressive decrease in VA
- glare, dimness, halos around lights at night, monocular diplopia
- "second sight" phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens (in nuclear sclerosis only)
  - patient may read without previously needed reading glasses
- diagnose by slit-lamp exam, and by noting changes in red reflex using ophthalmoscope
- may impair view of retina during fundoscopy

Treatment

- medical: attempt correction of refractive error, no strong evidence suggesting benefit of vitamin supplementation
- surgical: definitive treatment
  - indications for surgery
    - to improve visual function in patients whose visual loss leads to functional impairment (no need to wait for "ripe" cataract, may postpone surgery as long as one eye has sufficient vision)
    - to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
  - congenital or traumatic cataracts
  - phacoemulsification (phaco = lens)
  - most commonly used surgical technique (see Surgical Ophthalmology, OP44)
  - post-operative complications
    - RD, endophthalmitis, dislocated IOL, macular edema, glaucoma
    - with new foldable IOLs that have truncated edges, <10% of patients get posterior capsular opacification, which should be treated with YAG laser

Prognosis

- excellent if not complicated by other ocular disease

Dislocated Lens (Ectopia Lentis)

Etiology

- associated with Marfan's Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
- traumatic
Clinical Features
- decreased VA
- may get unilateral diplopia
- iridodenesis (quivering of iris with movement)
- direct ophthalmoscopy may elicit abnormal red reflex

Complications
- cataract, glaucoma, uveitis

Treatment
- surgical correction ± lens replacement

Vitreous
- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of eye
- normally adherent to optic disc, pars plana, and along major retinal blood vessels

Posterior Vitreous Detachment (PVD)

Etiology
- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, molecules that hold water condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

Clinical Features
- floaters, flashes of light

Complications
- traction at areas of abnormal vitreoretinal adhesions may cause retinal tears/detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

Treatment
- acute onset of PVD requires a dilated fundus exam to r/o retinal tears/detachment
- no specific treatment available for floaters/flashes of light

Vitreous Hemorrhage
- bleeding into the vitreous cavity

Etiology
- proliferative diabetic retinopathy (PDR)
- retinal tear/detachment
- PVD
- retinal vein occlusion
- trauma

Clinical Features
- sudden loss of VA
- may be preceded by many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

Treatment
- ultrasound (B-scan) to r/o retinal detachment
- expectant: in non-urgent cases (e.g. no retinal detachment), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± retinal detachment repair ± retinal endolaser to possible bleeding sites/vessels
**Endophthalmitis and Vitritis**

- intraocular infection: acute, subacute, or chronic

**Etiology**
- most commonly a postoperative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

**Clinical Features**
- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, hyphema, decreased IOP, etc.)

**Treatment** (see Ocular Trauma, OP42)
- **OCULAR EMERGENCY:** presenting vision best indicates prognosis
  - LP or worse: admission, immediate vitrectomy and intravitreal antibiotics to prevent loss of vision
  - HM or better: vitreous tap for culture and intravitreal antibiotics
  - topical fortified antibiotics

**Retina**

- composed of two parts (Figure 2)
  - neurosensory retina: comprises 9 of the 10 retinal layers, including the photoreceptors and the ganglion cell layer
  - retinal pigmented epithelium (RPE) layer: external to neurosensory retina
  - macula: rich in cones (for colour vision); most sensitive area of retina; looks darker due to lack of retinal vessels and thinning of retina in this region; 15° temporal and slightly below the optic disc
  - fovea: centre of macula; responsible for acute, fine vision
  - optic disc: slightly oval vertically, pinkish colour with centrally depressed yellow cup (normal cup:disc ratio is <0.5), retinal artery and vein pass through cup
  - ora serrata: irregularly-shaped, anterior margin of the retina (can only be visualized with indirect ophthalmoscopy of the far peripheral retina, or through a Goldmann 3 mirror lens)

**Central Retinal Artery Occlusion (CRAO)**

**Etiology**
- emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
- thrombus
- temporal arteritis

**Clinical Features**
- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD
- patient may have experienced transient episodes in the past (amaurosis fugax)
- fundoscopy
  - “cherry-red spot”
  - retinal pallor
  - narrowed arterioles, boxcarring (segmentation of blood in arteries)
  - cotton-wool spots (retinal infarcts)
  - cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations
  - after ~6 wk cherry-red spot recedes and optic disc pallor becomes evident

**Treatment**
- **OCULAR EMERGENCY:** attempt to restore blood flow within 2 h
  - the sooner the treatment = better prognosis (irreversible retinal damage if >90 min of complete CRAO)
  - massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
  - decrease intraocular pressure
    - topical β-blockers
    - inhaled oxygen-carbon dioxide mixture
    - IV acetazolamide
    - IV mannitol (draws fluid from eye)
  - drain aqueous fluid – anterior chamber paracentesis (carries risk of endophthalmitis)
  - treat underlying cause to prevent CRAO in other eye

**Endophthalmitis Vitrectomy Study**

For treatment of post-cataract surgery endophthalmitis:
- Intravitreal antibiotics preferred over systemic antibiotics
- Vitrectomy indicated only if vision LP or worse

**Figure 18. Retina**

**Hallmark of CRAO**
“Cherry-red spot” located at centre of macula (visualisation of unaffected highly vascular choroid through the thin fovea).

**Treatment for a central retinal artery occlusion (CRAO) must be initiated within 2 h of symptom onset for any hope of restoring vision.**
Branch Retinal Artery Occlusion (BRAO)
- only part of the retina becomes ischemic resulting in a visual field loss
- more likely to be of embolic etiology than CRAO; need to search for source
- management: ocular massage to dislodge embolus if VA is affected

Central/Branch Retinal Vein Occlusion (CRVO/BRVO)
- second most frequent "vascular" retinal disorder after DR
- usually a manifestation of a systemic disease (e.g. hypertension, diabetes mellitus)
- thrombus occurs within the lumen of the blood vessel

Predisposing Factors
- arteriosclerotic vascular disease
- hypertension
- diabetes mellitus
- glaucoma
- hyperviscosity (e.g. polycythemia rubra vera, sickle-cell disease, lymphoma, leukemia)
- drugs (e.g. oral contraceptive pill, diuretics)

Clinical Features
- painless, monocular, gradual or sudden visual loss
- ± RAPD
- fundoscopy
  - "blood and thunder" appearance
  - diffuse retinal hemorrhages, cotton-wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
  - venous stasis/non-ischemic retinopathy
    - no RAPD, VA approximately 20/80
    - mild hemorrhage, few cotton wool spots
    - resolves spontaneously over weeks to months
    - may regain normal vision if macula intact
  - hemorrhagic/ischemic retinopathy
    - usually older patient with deficient arterial supply
    - RAPD, VA approximately 20/200, reduced peripheral vision
    - more hemorrhages, cotton wool spots, congestion
    - poor visual prognosis

Complications
- degeneration of retinal pigment epithelium
- neovascularization of retina and iris (2° rubeosis), leading to 2° glaucoma
- vitreous hemorrhage
- macular edema

Treatment
- no treatment available to restore vision in CRVO/BRVO
- treat underlying cause/contributing factor
- fluorescein angiography to determine extent of retinal non-perfusion (risk of neovascularization)
- retinal laser photocoagulation, or intravitreal anti-VEGF injection to reduce retinal or iris neovascularization and prevent neovascular glaucoma
- macular grid laser photocoagulation for the treatment of macular edema in BRVO, not CRVO, intravitreal or slow-release biodegradable corticosteroid, or anti-VEGF injection is effective in the treatment of macular edema in both CRVO and BRVO

Retinal Detachment (RD)
- cleavage in the plane between the neurosensory retina and the retinal pigment epithelium (RPE)
- three types
  - rhegmatogenous (most common)
    - caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
    - tears may be caused by posterior vitreous detachment (PVD), degenerative retinal changes, trauma or iatrogenically
    - incidence increases with advancing age, in high myopes and after ocular surgery/trauma
  - tractional
    - caused by traction (due to vitreal, epiretinal, or subretinal membrane) pulling the neurosensory retina away from the underlying RPE
    - found in conditions such as DR, CRVO, sickle cell disease, ROP, and ocular trauma
  - exudative
    - caused by damage to the RPE resulting in fluid accumulation in the subretinal space
    - main causes are intraocular tumours, posterior uveitis, central serous retinopathy
Clinical Features
- sudden onset
- flashes of light
- due to mechanical stimulation of the retinal photoreceptors
- floaters
- hazy spots in the line of vision which move with eye position, due to drops of blood from torn vessels bleeding into the vitreous
- curtain of blackness/portal field loss
- darkness in one field of vision when the retina detaches in that area
- loss of central vision (if macula “off”)
- decreased IOP (usually 4-5 mmHg lower than the other, normal eye)
- ophthalmoscopy: detached retina is grey-white with surface blood vessels, loss of red reflex
- ± RAPD

Treatment
- prophylactic: symptomatic tear (flashes or floaters) can be sealed off with laser/cryotherapy, with the goal of preventing progression to detachment
- therapeutic
  - rhegmatogenous
    - scleral buckle procedure (see Surgical Ophthalmology, OP44)
  - pneumatic retinopexy (see Surgical Ophthalmology, OP44)
  - both treatments above are used in combination with localization of retinal tears/holes and subsequent treatment with cryotherapy or laser to create adhesions between the RPE and the neurosensory retina
  - vitrectomy plus injection of gas or silicone oil in cases of recurrent detachment
  - tractional
    - vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
    - exudative
    - treat underlying cause

Complications
- loss of vision, vitreous hemorrhage, recurrent retinal detachment
- a retinal detachment is an emergency, especially if the macula is still attached (macula "on")
- prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

Retinitis Pigmentosa
- worldwide incidence between 1/3500 and 1/7000 people
- many forms of inheritance, most commonly autosomal recessive (60%)
- hereditary degenerative disease of the retina manifested by rod > cone photoreceptor degeneration and retinal atrophy

Clinical Features
- night blindness, decreased peripheral vision ("tunnel vision"), decreased central vision (macular changes), glare (from cataract)

Investigations
- fundoscopy: areas of “bone-spicule” pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
- electrophysiological tests: electroretinography (ERG) and electrooculography (EOG) assist in diagnosis

Treatment
- no treatments available to reverse the condition; cataract extraction improves visual function; vitamin A and vitamin E supplementation can reduce progression of disease in some patients

Leber’s Congenital Amaurosis
- worldwide incidence 1/80,000
- inherited degeneration, autosomal recessive
- symptoms: resting nystagmus, sluggish or no papillary response, severe vision loss/blindness
- diagnosis: 11 types, confirmed by genetic testing
- management: no treatments available to reverse the conditions for most forms; one form (LCAS) shown to be successfully treatable by gene replacement using adeno-associated virus
Age-Related Macular Degeneration (ARMD)

- leading cause of irreversible blindness in the western world, associated with increasing age, usually bilateral
- 10% of people >65 yr old have some degree of ARMD
- female > male
degenerative changes are concentrated at the macula, thus only central vision is lost; peripheral vision (important for navigation) is maintained so patients can usually maintain an independent lifestyle

Classification
- Non-Exudative/“Dry” (Non-Neovascular) ARMD
  - most common type of ARMD (90% of cases)
  - slowly progressive loss of visual function
  - drusen: yellow-white deposits between the retinal pigment epithelium (RPE) and Bruch’s membrane (area separating inner choroidal vessels from RPE)
  - RPE atrophy: coalescence of depigmented RPE, clumps of focal hyperpigmentation or hypopigmentation
  - may progress to neovascular ARMD

- Exudative/“Wet” (Neovascular) ARMD
  - 10% of ARMD, but 80% of ARMD that results in severe visual loss
  - choroidal neovascularization: drusen predisposes to breaks in Bruch’s membrane causing subsequent growth and proliferation of choroidal capillaries
  - may lead to serous detachment of overlying RPE and retina, hemorrhage and lipid precipitates into subretinal space
  - can also lead to an elevated subretinal mass due to fibrous metaplasia of hemorrhagic retinal detachment
  - leads to disciform scarring and severe central visual loss

Risk Factors
- female
- increased age
- family history
- smoking
- Caucasian race
- blue irides

Clinical Features
- variable degree of progressive central visual loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations
- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assess degree of neovascularization – pathologic new vessels leak dye

Treatment
- non-neovascular “dry” ARMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed-circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visors
  - see Age-related Eye Disease Study (AREDS) sidebar
- neovascular “wet” ARMD
  - see Common Medications, OP44
  - laser photocoagulation for neovascularization
  - 50% of choroidal neovascularization cannot be treated initially
  - no definitive treatment for disciform scarring
  - PDT with verteporfin (Visudyne®)
  - IV injection of verteporfin followed by low intensity laser to area of choroidal neovascularization
  - intravitreal injection of anti-vascular endothelial growth factor (anti-VEGF)
  - pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®) (see OP45)

Exudative ARMD
- Hard/Soft Exudates: lipid deposits in the retina associated with diabetic retinopathy and hypertension
- Drusen vs. Exudate
  - Drusen: hyaline material secreted by RPE seen frequently in ARMD typically in peri-macular region
  - Hard/Soft Exudates: lipid deposits in the retina associated with diabetic retinopathy and hypertension

Exudative ARMD Lesions on Fluorescein Angiography
- Classic: well-defined leakage
- Occult: mottled or ill-defined leakage

Classified ARMD Lesions on Fluorescein Angiography
- Classic: well-defined leakage
- Occult: mottled or ill-defined leakage

Common Medications
- Age-related Eye Disease Study (AREDS) Study: A multicentre, single-blind, randomized controlled trial comparing the effects of ranibizumab and bevacizumab on visual acuity in patients with age-related macular degeneration (ARMD).
- Patients: 1208 patients aged 50 or more with age-related macular degeneration (ARMD).
- Intervention: Intravitreal injections of ranibizumab vs. intravitreal injections of bevacizumab.
- Results: The monthly use of either bevacizumab or ranibizumab results in the same visual acuity outcome. This finding holds true for the mean visual acuity and the proportion of patients who gain 15 letters, lose 15 letters, or remain stable. Equivalent visual-acuity outcomes were observed with both the monthly and the as-needed regimens of ranibizumab.
- Conclusion: This study supports the use of either bevacizumab or ranibizumab for the treatment of neovascular ARMD. The continued-global use of intravitreal bevacizumab is an equally effective, low-cost alternative to ranibizumab.
**Glucoma**

**Definition**
- progressive optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
- commonly associated with high IOP, but not required for diagnosis

**Background**
- aqueous is produced by the ciliary body and flows from the posterior chamber to the anterior chamber through the pupil, and drains into the episcleral veins via the trabecular meshwork and the Canal of Schlemm (Figure 20)
- an isolated increase in IOP is termed ocular hypertension (or glaucoma suspect) and these patients should be followed for increased risk of developing glaucoma (10% if IOP 20-30 mmHg; 40% if IOP 30-40 mmHg; and most if IOP >40 mmHg)
- pressures >21 mmHg are more likely to be associated with glaucoma; however, up to 50% of patients with glaucoma do not have IOP >21 mmHg
- loss of peripheral vision most commonly precedes central loss
- sequence of events: gradual pressure rise → increased C:D ratio → visual field loss

**Investigations**
- medical and family history
- VA testing
- slit lamp exam to assess anterior chamber depth
- ophthalmoscopy to assess the disc features
- tonometry by applanation or indentation to measure IOP
- visual field testing
- pachymetry to measure corneal thickness
- future follow-up includes optic disc examination, IOP measurement, and visual field testing to monitor course of disease

**Anti-angiogenic Therapy with Anti-vascular Endothelial Growth Factor Modalities for Neovascular Age-related Macular Degeneration**

**Cochrane DB Syst Rev** 2008;2:CD005139

**Study:** Cochrane systematic review of RCTs investigating the use of anti-VEGF (vascular endothelial growth factor) modalities for the treatment of wet age-related macular degeneration (ARMD).

**Patients:** Classic or occult wet type ARMD.

**Interventions:** Pegaptanib/Macugen® (aptamer comprised of ribonucleic acids that bind VEGF), ranibizumab/Lucentis® (anti VEGF fragment antibody) and verteporfin/Visudyne® photodynamic therapy (PDT).

**Results:** The MARINA trial showed that the pooled relative risk (RR) for a gain of 15 or more letters of visual acuity was 5.81 for ranibizumab versus placebo, while the FOCUS trial showed that the pooled RR for a gain of 15 or more letters at one year was 4.44 for a combination of ranibizumab + verteporfin PDT versus verteporfin PDT alone.

**Conclusion:** Ranibizumab offers significant benefit for the treatment of wet ARMD with significant improvements in best corrected visual acuity at one year.
Primary Open Angle Glaucoma (POAG)

- most common form, >95% of all glaucoma cases
- due to obstruction of aqueous drainage within the trabecular meshwork and its drainage into the Canal of Schlemm
- insidious and asymptomatic, screening is critical for early detection

Major Risk Factors

- elevated intraocular pressure (>21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic

Minor Risk Factors

- myopia
- hypertension
- diabetes
- hyperthyroidism (Graves’ disease)
- chronic topical ophthalmic steroid use in steroid responders – yearly eye exams recommended if >4 wk of steroid use
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

Clinical Features

- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
  - increased C: D ratio (vertical C: D >0.6)
  - significant C: D asymmetry between eyes (>0.2 difference)
  - thinning, notching of the neuroretinal rim
  - flame shaped disc hemorrhage
  - 360º of peripapillary atrophy
  - nerve fibre layer defect
  - large vessels become nasally displaced
- visual field loss
  - slow, progressive, irreversable loss of peripheral vision
  - paracentral defects, arcuate scotoma and nasal step are characteristics (Figure 19)
- late loss of central vision if untreated

Treatment

- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see Glaucoma Medications, Table 12, OP45)
  - increase aqueous outflow
    * topical cholinergics
    * topical prostaglandin analogues
    * topical α-adrenergics
  - decrease aqueous production
    * topical β-blockers
    * topical and oral carbonic anhydrase inhibitor
    * topical α-adrenergics
- laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
- trabeculectomy (see Surgical Ophthalmology, OP44)
- serial optic nerve head examinations, IOP measurements, and visual field testing to monitor disease course

Normal Tension Glaucoma

- POAG with IOP in normal range
- often found in women >60 but may occur earlier
- damage to optic nerve may be due to vascular insufficiency

Treatment

- treat reversible causes
Secondary Open Angle Glaucoma

- increased IOP 2° to ocular/systemic disorders that obstruct the trabecular meshwork
  - steroid-induced glaucoma
  - traumatic glaucoma
  - pigmentary dispersion syndrome
  - pseudoexfoliation syndrome

Primary Angle-Closure Glaucoma

- 5% of all glaucoma cases
- peripheral iris bows forward in an already susceptible eye with a shallow anterior chamber obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block, and results in inability of the aqueous to flow from the posterior chamber to the anterior chamber resulting in a sudden rise in IOP

Risk Factors

- hyperopia: small eye, big lens – large lens crowds the angle
- age >70
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

Clinical Features

- red, painful eye = RED FLAG
- unilateral, but other eye increased risk
- decreased visual acuity, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- corneal edema with conjunctival injection
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

Complications

- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synchiae, resulting in permanent angle closure

Treatment

- refer to ophthalmologist – acute angle closure glaucoma is an EMERGENCY
  - laser iridotomy
  - aqueous suppressants and hyperosmotic agents
- medical treatment (see Glaucoma Medications, Table 12, OP45)
  - miotic drops (pilocarpine) to reverse pupillary block
  - decrease IOP
    - topical β-blockers
    - topical adrenergics
    - topical cholinergics
      - pilocarpine 1-4% q15min, up to q5min
    - systemic carbonic anhydrase inhibitors
      - IV acetazolamide 250-500 mg
    - systemic hyperosmotic agents
      - oral glycerine 1 g/kg
      - IV mannitol 1 g/kg

Secondary Angle-Closure Glaucoma

Uveitis

- inflamed iris adheres to lens (posterior synchiae)

Neovascular Glaucoma

- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with proliferative diabetic retinopathy or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris vessels
Pupils

- pupil size is determined by the balance between the sphincter muscle and the dilator muscle
- sphincter muscle is innervated by the parasympathetic nervous system
  - carried by CN III; pre- and post-ganglionic fibres synapse in ciliary ganglion, and use acetylcholine as the neurotransmitter
- dilator muscle is innervated by the sympathetic nervous system (SNS)
  - first order neuron = hypothalamus → brainstem → spinal cord
  - second order preganglionic neuron = spinal cord → sympathetic trunk via internal carotid artery → superior cervical ganglion in neck
  - third order postganglionic fibres originate in the superior cervical ganglion, neurotransmitter is noradrenaline
  - as a diagnostic test, 4-10% cocaine prevents the re-uptake of noradrenaline, and will cause dilation of normal pupil, but not one with loss of sympathetic innervation (Horner’s Syndrome)
  - see Figure 8 in Neurology, N6

Pupillary Light Reflex

- light shone directly into eye travels along optic nerve (CN II, afferent limb) → optic tracts → bilateral midbrain
- impulses enter bilaterally in midbrain via pretectal area and Edinger-Westphal nuclei
- nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes

Pupil Abnormalities

Denervation Hypersensitivity
- when post-ganglionic fibres are damaged, the understimulated end-organ develops an excess of neuroreceptors and becomes hypersensitive
- postganglionic parasympathetic lesions (i.e. Adie’s pupil)
  - pupil will constrict with 0.125% pilocarpine (cholinergic agonist), normal pupil will not
- postganglionic sympathetic lesions (this test is used to differentiate between pre- and post-ganglionic lesions in Horner’s syndrome)
  - pupil will dilate with 0.125% adrenaline, normal pupil will not

Local Disorders of Iris
- posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
- ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o'clock positions resulting in a vertically oval pupil that reacts poorly to light
- trauma (e.g. post-intraocular surgery)

Anisocoria
- unequal pupil size
- idiopathic/physiologic anisocoria
  - 20% of population
  - round, regular, <1 mm difference
  - pupils reactive to light and accommodation
  - responds normally to mydriatics/miotics
- post eye surgery
- see Table 7 for other causes of anisocoria
**Patient with Anisocoria**

Relevant history and examination with specific attention to:
- History of ocular trauma
- Check old photographs (ptosis, ocular deviation, long standing anisocoria)
- Use of topical medications
- Exposure to toxins and drugs
- Associated ocular and neurologic symptoms/signs

**Which pupil is abnormal?**
Examine pupils in light and dark

- Anisocoria accentuated by darkness (small pupil abnormal)
  - Dilation lag
  - Ptosis
  - Test with 10% cocaine
  - Small pupil does not dilate
  - Horner’s syndrome
- Anisocoria equal in light and dark
  - Brisk reaction to light
  - Large pupil constricts
  - Large pupil does not constrict
  - Adie’s tonic pupil
  - Physiologic anisocoria
- Anisocoria accentuated by light (large pupil is abnormal)
  - Isolated sluggish to light
  - Light near dissociation
  - Use of 0.1% pilocarpine
  - Minimal/no constriction
  - Use of 0.1% pilocarpine
  - Pharmacologic anisocoria
  - Third nerve palsy

**Patient Must Fixate on Distant Target**

Figure 22. Approach to anisocoria

</table>
Dilated Pupil (Mydriasis)

Sympathetic Stimulation
- fight or flight response
- mydriatic drugs: epinephrine, dipivefrin (Propine®), phenylephrine

Parasympathetic Understimulation
- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
  - eye deviated down and out with ptosis present
  - etiology includes stroke, neoplasm, aneurysm, acute rise in ICP, diabetes mellitus (may spare pupil), trauma
  - CN III palsy will respond to drugs (e.g. pilocarpine), unlike a pupil dilated from medication (mydriatics)

Acute Angle-Closure Glaucoma
- fixed, mid-dilated pupil

Adie's Tonic Pupil
- 80% unilateral, females > males
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- if decreased deep tendon reflexes may be Adie's syndrome
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
  - dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
  - long-standing Adie's pupils are smaller than unaffected eye

Trauma
- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphincter ruptures

Constricted Pupil (Miosis)

Senile Miosis
- decreased sympathetic stimulation with age

Parasympathetic Stimulation
- local or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - cholinesterase inhibitor: phospholine iodide
  - opiates, barbiturates

Horner's Syndrome
- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis, anhydrosis of ipsilateral face/neck
- application of cocaine 4-10% (blocks reuptake of noradrenaline) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirms diagnosis
- hydroxyamphetamine 1% (stimulates noradrenaline release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- postganglionic lesions result in denervation hypersensitivity, which will cause pupil to dilate with 0.125% adrenaline, whereas normal pupil will not
- causes: carotid or subclavian aneurysm, brainstem infarct, demyelinating disease, cervical or mediastinal tumour, Pancoast tumour, goiter, cervical lymphadenopathy, surgical sympathectomy, Lyme disease, cervical ribs, tabes dorsalis, cervical vertebral fractures

Iritis
- miotic pupil initially
- later, may be irregularly shaped pupil due to posterior synechiae
- later stages non-reactive to light
Argyll-Robertson Pupil
- both pupils irregular and <3 mm in diameter, ± ptosis
- does not respond to light stimulation
- responds to accommodation (light-near dissociation)
- suggestive of neurosyphilis or other conditions (DM, encephalitis, MS, chronic alcoholism, CNS degenerative diseases)

Other Causes
- optic neuritis, retinal lesions

Relative Afferent Pupillary Defect (RAPD)

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light, caused by a lesion in visual afferent (sensory) pathway anterior to optic chiasm
- DDx: large retinal detachment, BRAO, CRAO, CRVO, advanced glaucoma, optic nerve compression, optic neuritis (most common)
- does not occur with media opacity (e.g. corneal edema, cataracts)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
  - if light is shone in the affected eye, direct and consensual response to light is decreased
  - if light is shone in the unaffected eye, direct and consensual response to light is normal
  - if the light is moved quickly from the unaffected eye to the affected eye, “paradoxical” dilation of both pupils occurs
  - observe red reflex, especially in patients with dark irides
- if the defect is bilateral there is no RAPD, as dilation is measured relative to the other eye

Cataracts never produce an RAPD.

It is possible to have RAPD and normal vision at the same time, e.g. in damaged superior colliculus caused by thalamic hemorrhage.

Differentiate RAPD from physiologic pupillary athetosis (“hippus”), which is rapid, rhythmic fluctuations of the pupil, with equal amplitude in both eyes.
Malignancies

• uncommon site for 1° malignancies
• eye usually affected secondarily by cancer or cancer treatments
• see Retinoblastoma, OP41

Lid Carcinoma

Etiology
• basal cell carcinoma (rodent ulcer) (90%)
  ▪ spread via local invasion, rarely metastasizes
  ▪ ulcerated centre, indurated base with pearly rolled edges, telangiectasia
• squamous cell carcinoma (<5%)
  ▪ spread via local invasion, may also spread to nodes and metastasize
  ▪ ulceration, keratosis of lesion
• sebaceous cell carcinoma (1-5%)
  ▪ often masquerades as chronic blepharitis or recurrent chalazion
  ▪ highly invasive, metastasize
• Kaposi’s sarcoma, malignant melanoma, Merkel cell tumour, metastatic tumour

Treatment
• incisional or excisional biopsies
• may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
• surgical reconstruction

Malignant Melanoma

• most common 1° intraocular malignancy in adults
• more prevalent in Caucasians
• arise from uveal tract, 90% choroidal melanoma
• hepatic metastases predominate

Treatment
• imaging to investigate spread
• depending on the size of the tumour, either radiotherapy, enucleation, limited surgery

Metastases

• most common intraocular malignancy in adults
• most commonly from breast and lung in adults, neuroblastoma in children
• usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
• may present with decreased or distorted vision, irregularly shaped pupil, iritis, hyphema

Treatment
• local radiation, chemotherapy
• enucleation if blind, painful eye

Ocular Manifestations of Systemic Disease

HIV/AIDS

• up to 75% of patients with AIDS have ocular manifestations

External Ocular Signs
• Kaposi’s sarcoma
  ▪ 2° to human herpes virus 8 (HHV-8), affects conjunctiva of lid or globe
  ▪ numerous vascular skin malignancies
  ▪ DDx: subconjunctival hemorrhage (non-clearing), hemangioma
• multiple molluscum contagiosum
• herpes simplex keratitis
• herpes zoster keratitis
Retina
- HIV retinopathy (most common)
  - cotton wool spots in >50% of HIV patients
  - intraretinal hemorrhage
- CMV retinitis
  - ocular opportunistic infection that develops in late stages of HIV when severely
    immunocompromised (CD4 count ≤50)
  - a necrotizing retinitis, with retinal hemorrhage and vasculitis, “brushfire” or “pizza pie”
    appearance
  - presents with scotomas (macular involvement and retinal detachment), blurred vision, and
    floaters
  - untreated infection will progress to other eye in 4-6 wk
- treatment: virostatic agents (e.g. gancyclovir or foscarnet) via IV or intravitreal injection
- necrotizing retinitis
  - from herpes simplex virus, herpes zoster, toxoplasmosis
- disseminated choroiditis
- Pneumocystis carinii, Mycobacterium avium intracellulare, Candida

Other Systemic Infections
- herpes zoster
  - see Herpes Zoster, OP19
- candidal endophthalmitis
  - fluffy, yellow-white, superficial retinal infiltrate that may eventually result in vitritis
  - may present with inflammation of the anterior chamber
- treatment: systemic amphotericin B, oral fluconazole
- toxoplasmosis
  - focal, grey-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous
    infiltration (vitreous cells)
  - can be congenital (transplacental) or acquired (caused by Toxoplasma gondii protozoa
    transmitted through raw meat and cat feces)
  - congenital form more often causes visual impairment (more likely to involve the macula)
  - treatment: pyrimethamine, sulfonamide, folinic acid, or clindamycin. Consider adding
    steroids if severe inflammation (vitrinitis, macular or optic nerve involvement)

Diabetes Mellitus (DM)
- see Endocrinology, E6
- most common cause of blindness in young people in North America
- consider DM if unexplained retinopathy, cataract, extraocular muscle palsy, optic neuropathy,
  sudden change in refractive error
- loss of vision due to:
  - progressive microangiopathy leading to macular edema
  - progressive diabetic retinopathy → neovascularization → traction → retinal detachment
  - vitreous hemorrhage
  - rubeosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

DIABETIC RETINOPATHY (DR)

Background
- altered vascular permeability (loss of pericytes, breakdown of blood-retinal barrier, thickening
  of basement membrane)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

Classification
- non-proliferative: increased vascular permeability and retinal ischemia
  - microaneurysms
  - dot and blot hemorrhages
  - hard exudates (lipid deposits), non-specific for DR
  - macular edema
- advanced non-proliferative (or pre-proliferative):
  - non-proliferative findings plus:
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular anomalies (IRMA) in 1 of 4 retinal quadrants
      - IRMA: dilated, leaky vessels within the retina
    - cotton wool spots (nerve fibre layer infarcts)

Diabetes Mellitus (DM)
- see Endocrinology, E6
- most common cause of blindness in young people in North America
- consider DM if unexplained retinopathy, cataract, extraocular muscle palsy, optic neuropathy,
  sudden change in refractive error
- loss of vision due to:
  - progressive microangiopathy leading to macular edema
  - progressive diabetic retinopathy → neovascularization → traction → retinal detachment
  - vitreous hemorrhage
  - rubeosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

DIABETIC RETINOPATHY (DR)

Background
- altered vascular permeability (loss of pericytes, breakdown of blood-retinal barrier, thickening
  of basement membrane)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

Classification
- non-proliferative: increased vascular permeability and retinal ischemia
  - microaneurysms
  - dot and blot hemorrhages
  - hard exudates (lipid deposits), non-specific for DR
  - macular edema
- advanced non-proliferative (or pre-proliferative):
  - non-proliferative findings plus:
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular anomalies (IRMA) in 1 of 4 retinal quadrants
      - IRMA: dilated, leaky vessels within the retina
    - cotton wool spots (nerve fibre layer infarcts)
• proliferative:
  ▪ 5% of patients with diabetes will reach this stage
  ▪ neovascularization of iris, disc, retina to vitreous
  ▪ neovascularization of iris (rubeosis iridis) can lead to neovascular glaucoma
  ▪ vitreous hemorrhage from bleeding, fragile new vessels, fibrous tissue can contract causing tractional retinal detachment
  ▪ high risk of severe visual loss 2° to vitreous hemorrhage, retinal detachment

Screening Guidelines for Diabetic Retinopathy
• type 1 DM
  ▪ screen for retinopathy beginning annually 5 yr after disease onset
  ▪ annual screening indicated for all patients over 12 yr and/or entering puberty
• type 2 DM
  ▪ initial examination at time of diagnosis, then annually
• pregnancy
  ▪ oculary exam in 1st trimester, close follow-up throughout as pregnancy can exacerbate DR
  ▪ gestational diabetics are not at risk for diabetic retinopathy

Treatment
• Diabetic Control and Complications Trial (DCCT)
  ▪ tight control of blood sugar decreases frequency and severity of microvascular complications
  ▪ blood pressure control
  ▪ focal laser for clinically significant macular edema, intravitreal injection of corticosteroid or anti-VEGF for focal involved diabetic macular edema
• panretinal laser photocoagulation for proliferative diabetic retinopathy; reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand → reduces risk of blindness
  ▪ vitrectomy for non-clearing vitreous hemorrhage and retinal detachment in proliferative diabetic retinopathy
  ▪ vitrectomy before vitreous hemorrhage does not improve the visual prognosis

Lens Changes
• earlier onset of senile nuclear sclerosis and cortical cataract
• may get hyperglycemic cataract, due to sorbitol accumulation (rare)
• changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3–4 diopters

Extraocular Muscle Palsy
• usually CN III infarct
• pupil usually spared in diabetic CN III palsy, but ptosis is observed
• may involve CN IV and VI
• usually recover within few months

Optic Neuropathy
• visual acuity loss due to infarction of optic disc/nerve

---

*Figure 25. DM vs. HTN retinopathy*
Hypertension

- retinopathy is the most common ocular manifestation
- chronic HTN retinopathy: arteriovenous (AV) nicking, blot retinal hemorrhages, microaneurysms, cotton wool spots
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema

Multiple Sclerosis (MS)

- see Neurology, N46

Clinical Features

- blurred vision and decreased colour vision: 2° to optic neuritis
- central scotoma: due to damage to papillomacular bundle of retinal nerve fibres
- diplopia: 2° to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

Treatment

- IV steroids with taper to oral form for optic neuritis
  - DO NOT treat with oral steroids in isolation as this increases likelihood of eventual development of MS

TIA/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles)

Graves’ Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur 2° to sympathetic overdrive and/or specific inflammatory infiltrate of the orbital tissue

Clinical

- initial inflammatory phase is followed by a quiescent cicatricial phase

Treatment

- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, proptosis and compressive optic neuropathy with one or a combination of:
  - steroids (during acute phase)
  - orbital bony decompression
  - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjogren's syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)
Giant Cell Arteritis (GCA)/Temporal Arteritis

- see Rheumatology, RH20

Clinical
- more common in women >60 yr
- abrupt monocular loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and past medical history of polymyalgia rheumatica
- ischemic optic atrophy
  - 50% lose vision in other eye if untreated

Diagnosis
- temporal artery biopsy + increased ESR (ESR can be normal, but likely 80-100 in first hour), CRP
- if biopsy of one side is negative, biopsy the other side

Treatment
- high dose corticosteroid to relieve pain and prevent further ischemic episodes
- if diagnosis of GCA is suspected clinically: start treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation (DO NOT WAIT TO TREAT)

Sarcoidosis
- granulomatous uveitis with large “mutton fat” keratitic precipitates and posterior synechiae
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

Treatment
- steroids and mydriatics

Pediatric Ophthalmology

Strabismus
- ocular misalignment in one or both eyes, found in 3% of children
- object not visualized simultaneously by fovea of each eye
- terms used to describe strabismus depend upon:
  - direction of deviation relative to the fixating eye
  - conditions under which it presents: ‘latent’, ‘manifest’ misalignment
  - change with the position of gaze: ‘comitant’ (usually nonparalytic), ‘incomitant’ (usually occurs with paralytic or restrictive strabismus)
- often presents with parental concern about a wandering eye, crossing eye, or poor vision
- elicit a detailed family history of strabismus, amblyopia, type of eyeglasses and history of wear, extraocular muscle surgery or other eye surgery, and genetic diseases to identify children at higher risk
- distinguish from pseudostrabismus (prominent epicanthal folds, hypertelorism, markedly positive or negative angle κ)
- complications: amblyopia, cosmesis

HETEROTROPIA
- manifest deviation
- deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

Types
- exo- (lateral deviation), eso- (medial deviation)
- hyper- (upward deviation), hypo- (downward deviation)
- esotropia = “crossed-eyes”; exotropia = “wall-eyed”

Differentiate from Pseudostrabismus
- prominent epicanthal folds: give appearance of esotropia but Hirschberg test is normal, more common in Asians
- markedly elevated angle κ (the angle formed by the pupillary axis and the visual axis at the centre of the pupil)
  - caused by the failure of optical axis of the eye and the visual axis to coincide
  - a small positive (up to 5°) angle κ is physiologic
  - a large positive angle κ (nasally deviated fovea) simulates eso-appearance
  - a large negative angle κ (temporally deviated fovea) gives an exo-appearance

ESR in Temporal Arteritis
- Males > age/2
- Females > (age + 10)/2

Does this Patient have Temporal Arteritis?
JAMA 2002;287:92-101
Rule in: jaw claudication and diplopia on history, temporal artery beading, prominence of the artery and tenderness over the artery on exam.
Rule out: no temporal artery abnormalities on exam, normal ESR.

Strabismus in children under 4 mo of age sometimes resolves, particularly if the deviation is intermittent, variable or measures less than 40 prism diopters
Tests

- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
  - light reflex lateral to central cornea indicates esodeviation; light reflex medial to central cornea indicates exodeviation
  - false positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle κ)
- cover test (Figure 26)
- the deviation can be quantified using prisms

HETEROPHORIA

- latent deviation
- deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
- Hirschberg test will be normal (light reflexes symmetrical)
- very common – majority are asymptomatic
- may be exacerbated or become manifest with asthenopia (eye strain, fatigue)

Tests

- cover-uncover test
- alternate cover test
  - alternating the cover between both eyes reveals the total deviation, both latent and manifest
  - maintain cover over one eye for 2-3 s before rapidly shifting to other eye

Figure 26. Cover and cover-uncover tests for detection of tropias and phorias

Table 9. Paralytic vs. Non-Paralytic Strabismus

<table>

</tbody>
</table>
Accommodative Esotropia

- normal response to approaching object is the triad of the near reflex: convergence, accommodation and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over-activation of the near reflex
- average age of onset is 2.5 yr
- usually reversible with correction of refractive error

Non-accommodative Esotropia

- accounts for 50% of childhood strabismus
- most are idiopathic
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

Amblyopia

Definition

- a neurodevelopmental visual disorder with unilateral (or less commonly, bilateral) reduction of best corrected visual acuity that cannot be attributed only and directly to the effect of a structural abnormality of the eye. It is caused by abnormal visual experience early in life and cannot be remedied immediately by spectacle glasses alone
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia). Other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors), and concomitant structural ocular problems

Detection

- “Holler Test”: young child upset if good eye is covered
- quantitative visual acuity by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
- prognosis: 90% will have good vision restored and maintained if treated <4 yr old

Etiology and Management

- strabismus
  - correct with glasses for accommodative esotropia (50% of children experience relief of their esotropia with glasses and will not require surgery)
  - occlusion of unaffected eye forces brain to use previously strabismic eye; aims to bring vision in previously suppressed eye to normal before surgery
  - surgery: recession (weakening) – moving muscle insertion further back on the globe; or resection (strengthening) – shortening the muscle
  - botulinum toxin for single muscle weakening
  - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until approximately age 8 yr
- anisometropia
  - amblyopia usually in the more hyperopic eye
  - the more emmetropic (normal refraction) eye receives a clear image while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
  - treat with glasses to correct refractive error
  - patching is required if visual acuity difference persists after 4-8 wk of using glasses
- deprivation amblyopia
  - occlusion due to ptosis, cataract, retinoblastoma, corneal opacity
  - occlusion amblyopia: prolonged patching of good eye may cause it to become amblyopic

Oclusion Therapy

- patching the good eye to force the brain to use the non-dominant eye and redevelop its vision
- atropine cycloplegic drops to impair accommodation and blur vision of the better seeing eye

Risks

- permanent loss of vision in the affected eye
- possibility of injury to ‘remaining’ good eye
  - safety glasses or polycarbonate lenses recommended if visual acuity in worse eye is less than 20/50
- loss of stereopsis
Leukocoria

- white reflex (red reflex is absent)

Differential Diagnosis
- cataract
- retinoblastoma
- retinal coloboma
- ROP
- persistent hyperplastic primary vitreous
- Coats' disease (exudative retinal telangiectasis)
- toxocariasis
- retinal detachment

Retinoblastoma

- most common primary intraocular malignancy in children
- incidence: 1/15,000; sporadic or genetic transmission; screening of siblings/offspring essential
- unilateral or bilateral (in 1/3 of cases)
- malignant – direct or hematogenous spread
- diagnosis
  - often presents with leukocoria or strabismus
  - U/S or CT scan may demonstrate calcified mass (present in most cases)

Treatment
- radiotherapy, chemotherapy combined with laser, cryopexy, and/or enucleation

Retinopathy of Prematurity (ROP)

- vasoproliferative retinopathy that is a major cause of blindness in the developed world

Risk Factors
- non-black race (black infants have lower risk of developing ROP)
- low gestational age, birth weight <1500 g
- high oxygen exposure after birth

Classification (ROP Staging)
- stage 1: faint demarcation line at the junction between the vascularized and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial retinal detachment (4A: macula "on", 4B: macula "off")
- stage 5: total retinal detachment
- plus (+) disease: dilatation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with 5 continuous or 8 cumulative clock hours of ROP involvement

Treatment
- threshold disease is treated with cryotherapy or laser (laser is now the standard treatment, with better refractive outcome), off label anti-VEGF intravitreal injections (see sidebar)
- ROP beyond threshold level is either watched carefully (usually stage 4A) or treated with vitrectomy/scleral buckle

Prognosis
- higher incidence of myopia among ROP infants, even if treated successfully
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

Nasolacrimal System Defects

- congenital obstruction of the nasolacrimal duct (failure of canalization), usually occurs at 1-2 mo of age
- epiphora, crusting, discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac
- treatment: massage over lacrimal sac at medial corner of eyelid
- vast majority spontaneously resolve in 9-12 mo, otherwise consider referral for duct probing
Ophthalmia Neonatorum

- newborn conjunctivitis in first month of life
- causes:
  - toxic: silver nitrate, erythromycin
  - infectious: bacterial (e.g. *Neisseria gonorrhoeae* – most common, *Chlamydia trachomatis*), herpes simplex virus
- diagnose using stains and cultures
- treatment: systemic antibiotics with possible hospitalization if infectious etiology
- topical prophylaxis, most commonly with erythromycin (or silver nitrate), is required by law at birth

Congenital Glaucoma

- due to inadequate development of the filtering mechanism of the anterior chamber angle

Clinical Features

- cloudy cornea, increased IOP
- photophobia, epiphora
- buphthalmos (large cornea, "ox eye", 2" to increased IOP), blepharospasm

Treatment

- filtration surgery is required soon after birth to prevent blindness

Ocular Trauma

Blunt Trauma

- caused by blunt object such as fist, squash ball
- history: injury, ocular history, drug allergy, tetanus status
- exam: VA first, pupil size and reaction, EOM (diplopia), external and slit lamp exam, ophthalmoscopy
- if VA normal or slightly reduced, globe less likely to be perforated
- if VA reduced may be perforated globe, corneal abrasion, lens dislocation, retinal tear
- bone fractures
  - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
  - ethmoid fracture: subcutaneous emphysema of lid
- lids: swelling, laceration, emphysema
- conjunctiva: subconjunctival hemorrhage
- cornea: abrasion – detect with fluorescein staining and cobalt blue filter using slit lamp or ophthalmoscope
- anterior chamber: assess depth, hyphema, hypopyon
- iris: prolapse, iritis
- lens: cataract, dislocation
- retinal tear/detachment

Penetrating Trauma

- include ruptured globe ± prolapsed iris, intraocular foreign body
- rule out intraocular foreign body, especially if history of "metal striking metal", orbit CT
- initial management: REFER IMMEDIATELY
  - ABCs
  - don’t press on eye globe!
  - don’t check IOP if possibility of globe rupture
  - check vision, diplopia
  - apply rigid eye shield to minimize further trauma
  - keep head elevated 30-45° to keep IOP down
  - keep NPO
  - tetanus status
  - give IV antibiotics
  - selecting appropriate agents depends on the mechanism of injury. Gram positive bacteria are more commonly involved than gram negatives. Retained intraocular foreign objects increase the risk of infections with Bacillus species, whereas exposure to vegetable matter increased the risk of a fungal etiology
Hyphema

- blood in anterior chamber often due to damage to root of the iris
- may occur with blunt trauma

Treatment
- refer to ophthalmology
  - shield and bedrest x 5 d or as determined by ophthalmologist
  - sleep with head upright
- may need surgical drainage if hyphema persists or if re-bleed

Complications
- risk of re-bleed highest on days 2-5, resulting in 2° glaucoma, corneal staining, and iris necrosis
- never prescribe Aspirin®, as it increases the risk of a re-bleed

Blow-Out Fracture

- see Plastic Surgery, PL31
- blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
- orbital rim remains intact
- inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
- infraorbital nerve courses along the floor of the orbit and may be damaged

Clinical Features
- pain and nausea at time of injury
- diplopia, restriction of EOM
- infraorbital and upper lip paresthesia (CN V2)
- enophthalmos (sunken eye), periorbital ecchymoses

Investigations
- plain films: Waters’ view and lateral
- CT: anteroposterior and coronal view of orbits

Treatment
- refrain from coughing, blowing nose
- systemic antibiotics may be indicated
- surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
- may delay surgery if the diplopia improves

Chemical Burns

- alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
- poor prognosis if cornea opaque, likely irreversible stromal damage
- even with a clear cornea initially, alkali burns can progress for weeks (thus, very guarded prognosis)

Treatment
- immediately irrigate at site of accident with water or buffered solution
  - IV drip for at least 20-30 min with eyelids retracted in emergency department
  - swab upper and lower fornices to remove possible particulate matter
- do not attempt to neutralize because the heat produced by the reaction will damage the cornea
- cycloplegic drops to decrease iris spasm (pain) and prevent 2° glaucoma (due to posterior synechiae formation)
- topical antibiotics and patching
- topical steroids (by ophthalmologist) to decrease inflammation, use for less than 2 wk (in the case of a persistent epithelial defect)

Fluorescein lights up alkali so you can detect it and assess whether it has been removed.

Shaken Baby Syndrome

- Syndrome of findings characterized by absence of external signs of abuse with respiratory arrest, seizures, or coma. Ocular exam findings are important diagnostically for Shaken Baby Syndrome. These findings include extensive retinal and vitreous hemorrhages that occur during the shaking process and are extremely rare in accidental trauma. A detailed fundoscopic exam or an ophthalmology referral should be conducted for all infants in whom abuse is suspected.

Classic Signs of Blow-Out
- Enophthalmos
- Decreased upgaze (IR trapped)
- Cheek anesthetized (infraorbital nerve trapped)
Surgical Ophthalmology

- **dacrocystorhinostomy (DCR):** excision of bone covering the nasolacrimal sac to restore tear drainage
- **LASIK (laser-assisted in-situ keratomileusis):** a microkeratome is used to create a corneal flap followed by laser remodeling of the stroma to correct refractive error
- ** trabeculectomy:** creation of a new outflow tract from anterior chamber to under conjunctiva; fibrosis prevented with mitomycin C or 5-FU injection during surgery
- **phacoemulsification (cataract extraction):** the use of ultrasonic waves to break up and aspirate a cataract followed by replacement with an artificial lens implant
- **vitrectomy:** the use of small trochars to enter the posterior segment and remove vitreous; commonly used to treat vitreous hemorrhage and retinal detachment
- **pneumatic retinopexy:** intraocular injection of air or an expandable gas in order to tamponade a retinal break for repair of retinal detachment
- **scleral buckle:** a band is secured on the outside of the globe that indents the eye wall, thereby relieving vitreous traction on the retina around any tears/holes and allowing the tears/holes to remain sealed

Common Medications

**TOPICAL OCULAR DIAGNOSTIC DRUGS**

**Fluorescein Dye**
- water soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope or slit lamp)
- absorbed in areas of epithelial loss (ulcer or abrasion)
- also stains mucus and contact lenses

**Rose Bengal Stain**
- stains devitalized epithelial cells and mucus
Anesthetics
- e.g. proparacaine HCl 0.5%, tetracaine 0.5%
- indications: removal of foreign body and sutures, tonometry, examination of painful cornea
- toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore NEVER prescribe

Mydriatics
- dilate pupils
- two classes
  - cholinergic blocking (e.g. tropicamide – Mydriacyl®)
    - dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
    - indications: refraction, ophthalmoscopy, therapy for iritis
  - adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
    - stimulate pupillary dilator muscles, no effect on accommodation
    - usually used with tropicamide for additive effects
- side effects: hypertension, tachycardia, arrhythmias

WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

Vascular Endothelial Growth Factors (VEGF) Inhibitors
- block vascular endothelial growth factor which prevents ocular angiogenesis and further development of choroidal neovascularization
- administered via intravitreal injections
- pegaptanib (Macugen®) is a selective anti-VEGF targeting VEGF isoform 165 (no longer widely used)
- ranibizumab (Lucentis®) is a non-selective anti-VEGF agent
- bevacizumab (Avastin®) is another non-selective anti-VEGF agent but is only FDA approved for metastatic breast cancer, colorectal cancer and non-small cell lung cancer. Therefore, its ophthalmologic use is off-label
TOPICAL OCULAR THERAPEUTIC DRUGS

NSAIDs
- used for less serious chronic inflammatory conditions
- e.g. ketorolac (Acular®), diclofenac (Voltaren®), nepafenac (Nevanac®) drops

Anti-Histamines
- used to relieve red and itchy eye, often in combination with decongestants
- sodium cromoglycate – stabilizes membranes

Decongestants
- weak adrenergic stimulating drugs (vasoconstrictor)
- e.g. naphazoline, phenylephrine ( Isopto Frin®)
- rebound vasodilation with overuse; rarely can precipitate angle closure glaucoma

Antibiotics
- indications: bacterial conjunctivitis, keratitis, or blepharitis
- commonly as topical drops or ointments, may give systemically
- e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), gentamicin (Garamycin®), erythromycin, tetracycline, bacitracin, polymyxin B, fluoroquinolones (ciprofloxacin [Ciloxan®], ofloxacin [ Ocuflox®], moxifloxacin [Vigamox®], gatifloxacin [Zymar®])

Corticosteroids
- e.g. fluorometholone (FML®), betamethasone, dexamethasone (Maxidex®), prednisolone ( Predsol® 0.5%, Pred Forte® 1%), rimexolone (Vexol®), loteprednol etabonate 0.5% (Lotamax®)
- primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
- complications
  ▪ potentiates HSV keratitis and fungal keratitis as well as mask symptoms
  ▪ increased IOP, more rapidly in steroid responders (within weeks)
  ▪ posterior subcapsular cataract (within months)

Acronyms

AC  acromioclavicular
ACL  anterior cruciate ligament
AIN  anterior interosseous nerve
ARDS acute respiratory distress syndrome
AVN  avascular necrosis
CA  coracoclavicular
CC  coracoclavicular
CRPS complex regional pain syndrome
DDH  developmental dysplasia of the hip
DRUJ  distal radioulnar joint
DVT  deep vein thrombosis
EtOH  ethanol/alcohol

FOOSH fall on outstretched hand
GA  general anesthetic
HD  heterotopic ossification
IBD  incision and drainage
IM  intramedullary
LCL  lateral collateral ligament
MCL  medial collateral ligament
MT  metatarsal
MTP  metatarsal phalangeal
MVC  motor vehicle collision
NVS  neurovascular status
NWB  non-weight bearing

OA  osteoarthritis
ORIF  open reduction internal fixation
PCL  posterior cruciate ligament
PE  pulmonary embolism
PIN  posterior interosseous nerve
RA  rheumatoid arthritis
RGI  range of motion
RSI  reflex sympathetic dystrophy
SCFE  slipped capital femoral epiphysis
SLAP  superior lateral, anterior posterior
SN  sensitivity
THA  total hip arthroplasty

Differential Diagnosis of Joint Pain

**Figure 3. Nerves and arteries of lower limbs**

**Figure 4. Intrinsic vs. extrinsic joint pain**
Fractures – General Principles

Fracture Description

1. Integrity of Skin/Soft Tissue
   - closed: skin/soft tissue over and near fracture is intact
   - open: skin/soft tissue over and near fracture is lacerated or abraded, fracture exposed to outside environment
     - signs: continuous bleeding from puncture site or fat droplets in blood are suggestive of an open fracture

2. Location (Figure 5)
   - epiphyseal: end of bone, forming part of the adjacent joint
   - metaphyseal: the flared portion of the bone at the ends of the shaft
   - diaphyseal: the shaft of a long bone (proximal, middle, distal)
   - physis: growth plate

3. Orientation/Fracture Pattern (Figure 6)
   - transverse: fracture line perpendicular to long axis of bone; direct high energy force
   - oblique: angular fracture line; angular or rotational force
   - butterfly: fracture site fragment which looks like a butterfly
   - segmental: a separate segment of bone bordered by fracture lines; high energy
   - spiral: complex, multi-planar fracture line; rotational force, low energy
   - comminuted/multi-fragmentary: more than 2 fracture fragments
   - intra-articular: fracture line crosses articular cartilage and enters joint
   - avulsion: tendon or ligament tears/pulls fragment off bone; often in children, high energy
   - torus: a buckle fracture of one cortex, often in children (Figure 51, OR38)
   - green-stick: an incomplete fracture of one cortex, often in children (Figure 51, OR38)
   - pathologic: fracture through bone weakened by disease/tumour

4. Displacement (Figure 6)
   - nondisplaced: fracture fragments are in anatomic alignment
   - displaced: fracture fragments are not in anatomic alignment
   - distracted: fracture fragments are separated by a gap
   - angulated: direction of fracture apex, e.g. varus/valgus
   - translated: percentage of overlapping bone at fracture site
   - rotated: fracture fragment rotated about long axis of bone

Management of Fractures

- ABCs, primary survey and secondary survey (ATLS protocol)
  - rule out other fractures/injuries
  - rule out open fracture (see sidebar on OR8)
- AMPLE history: Allergies, Medications, Past medical history, Last meal, Events surrounding injury
  - consider pathologic fracture with history of only minor trauma
- analgesia
- imaging
- splint extremity

Figure 5. Schematic diagram of the long bone

X-Ray Rule of 2s
2 sides = bilateral
2 views = AP + lateral
2 joints = joint above + below
2 times = before + after reduction

Varus/Valgus Angulation
Varus = Apex away from midline
Valgus = Apex toward midline

Displacement
Refers to position of the distal fragment relative to the proximal fragment.

Quick Nerve Exam
"Thumbs Up": PIN (Radial Nerve)  
"OK Sign": AIN (Median Nerve) 
"Spread Fingers": Ulnar Nerve

Reasons for Splinting
- Pain control
- Reduces further damage to vessels, nerves, and skin
- Reduces risk of inadvertently converting closed to open fracture
- Facilitates patient transport
1. obtain the reduction (refer to Table 27 for appropriate IV sedation)
   - closed reduction
   - apply traction in the long axis of the limb
   - reverse the mechanism that produced the fracture
   - reduce with IV sedation and muscle relaxation (fluoroscopy can be used if available)
   - indications for open reduction:
     - NO CAST
     - other indications include:
       - failed closed reduction
       - not able to cast or apply traction due to site (e.g. hip fracture)
       - pathologic fractures
       - potential for improved function with ORIF
   - re-check neurovascular status after reduction and obtain post-reduction x-ray

2. maintain the reduction
   - external stabilization: splints, casts, traction, external fixator
   - internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), intramedullary fixation (rods)
   - follow-up: evaluate bone healing

3. rehabilitate to regain function and avoid joint stiffness

Fracture Healing

Normal Healing

<table>
<thead>
<tr>
<th>Time</th>
<th>Description</th>

Orthopedic Emergencies

Trauma Patient Work-Up

Etiology
- high energy trauma e.g. motor vehicle accident, fall from height
- may be associated with spinal injuries or life-threatening visceral injuries

Clinical Presentation
- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension/hypovolemia
- consider involvement of alcohol or other substances

Investigations
- trauma survey (see Emergency Medicine, ER2)
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral of all bones suspected to be injured
- other views of pelvis: AP, inlet and outlet; Judet views for acetabular fracture (see Table 18 for classification of pelvic fractures)
**Treatment**
- ABCDEs and initiate resuscitation for life threatening injuries
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- DVT prophylaxis

**Complications**
- hemorrhage – life threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome (SOB, hypoxemia, petechial rash, thrombocytopenia and neurological symptoms)
- venous thrombosis – DVT and PE
- bladder/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic osteoarthritis of joints with intra-articular fractures
- sepsis if missed open fracture

**Open Fractures**

**Definition**
- fractured bone and hematoma in communication with the external environment

**Emergency Measures**
- removal of obvious foreign material
- irrigate with normal saline if grossly contaminated
- cover wound with sterile dressings
- immediate IV antibiotics (see Table 4)
- tetanus toxoid or immunoglobulin as needed
- reduce and splint fracture
- NPO and prepare for OR (bloodwork, consent, ECG, CXR)
- operative irrigation and debridement within 6-8 h to decrease risk of infection
- traumatic wound often left open to drain but vacuum-assisted closure dressing may be used
- re-examine with repeat I&D in 48 h

**Table 4. Gustilo Classification of Open Fractures**

<table>
<thead>
<tr>
<th>Gustilo Grade</th>
<th>Length of Open Wound</th>
<th>Description</th>
<th>Prophylactic Antibiotic Regimen</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>&lt;1 cm</td>
<td>Minimal contamination and soft tissue injury Simple or minimally comminuted fracture</td>
<td>First generation cephalosporin (cefazolin) for 3 d If allergy use fluoroquinolone If MRSA +ve use vancomycin</td>
</tr>
<tr>
<td>II</td>
<td>1-10 cm</td>
<td>Moderate contamination Soft tissue injury</td>
<td>First generation cephalosporin (cefazolin) for 3 d plus Gram-negative coverage (gentamicin) for at least 3 d</td>
</tr>
<tr>
<td>III*</td>
<td>&gt;10 cm</td>
<td>IIIA: Extensive soft tissue injury with adequate ability of soft tissue to cover wound IIB: Extensive soft tissue injury with periosteal stripping and bone exposure; inadequate soft tissue to cover wound IIIc: Vascular injury/compromise</td>
<td>As per Grade II For soil contamination, penicillin is added for clostridial coverage</td>
</tr>
</tbody>
</table>

*Any high energy, comminuted fracture, shot gun, farmyard/soil/water contamination, exposure to oral flora, or fracture more than 8 h old is immediately classified as Grade III

**Cauda Equina Syndrome**
- see Neurosurgery, NS26

**Compartment Syndrome**

**Definition**
- increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment) with little room for expansion
- interstitial pressure exceeds capillary perfusion pressure leading to muscle necrosis (in 4-6 h) and eventually nerve necrosis

**Etiology**
- intracompartamental: fracture (particularly tibial shaft fractures, pediatric supracondylar fractures, and forearm fractures), crush injury, ischemia-reperfusion injury
- extracompartamental: constrictive dressing (circumferential cast, poor positioning during surgery), circumferential burn
Figure 9. Pathogenesis of compartment syndrome

Clinical Features
- pain with active contraction of compartment
- pain with passive stretch
- swollen, tense compartment
- suspicious history
- 5 Ps: late sign (see sidebar) – do not wait for these to develop to make the diagnosis!

Investigations
- usually not necessary as compartment syndrome is a clinical diagnosis
- in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter AFTER clinical diagnosis is made (normal = 0 mmHg; elevated ≥30 mmHg or ≤30 mmHg of diastolic BP)

Treatment
- non-operative
  - remove constrictive dressings (casts, splints), elevate limb at the level of the heart
- operative
  - urgent fasciotomy
  - 48-72 h post-op: wound closure ± necrotic tissue debridement

Complications
- rhabdomyolysis, renal failure secondary to myoglobinuria
- Volkmann's ischemic contracture: ischemic necrosis of muscle, followed by secondary fibrosis and finally calcification; especially following supracondylar fracture of humerus

Articular Cartilage

Properties
- 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
- avascular (nutrition from synovial fluid), aneural, alymphatic
- composed of: collagen (90% is type II; gives tensile strength), water, proteoglycans (gives compressive strength), and chondrocytes

ARTICULAR CARTILAGE DEFECTS

Etiology
- overt trauma, repetitive minor trauma (such as patellar maltracking); common sports injury
- degenerative conditions such as early stage osteoarthritis or osteochondritis dissecans

Clinical Features
- similar to symptoms of osteoarthritis (joint line pain with possible effusion, etc.)
- often have predisposing factors, such as ligament injury, malalignment of the joint (varus/valgus), obesity, bone deficiency (avascular necrosis, osteochondritis dissecans, ganglion bone cysts), inflammatory arthropathy, and familial osteoarthropathy
- may have symptoms of locking or catching related to the torn/displaced cartilage

Investigations
- x-ray (to rule out bony defects and check alignment)
- MRI
- diagnostic arthroscopy (treatment is often guided by what is seen during arthroscopy)
Table 5. Outerbridge Classification of Chondral Defects

<table>
<thead>
<tr>
<th>Grade</th>
<th>Chondral Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Softening and swelling of cartilage</td>
</tr>
<tr>
<td>II</td>
<td>Fragmentation and fissuring &lt;1/2 inch in diameter</td>
</tr>
<tr>
<td>III</td>
<td>Fragmentation and fissuring &gt;1/2 inch in diameter</td>
</tr>
<tr>
<td>IV</td>
<td>Erosion of cartilage down to bone</td>
</tr>
</tbody>
</table>

**Treatment**
- individualized; must take into account patient factors (age, skeletal maturity, activity level, etc.) and defect factors (Outerbridge classification, subchondral bone involvement, etc.)
- non-operative: rest, NSAIDs, bracing
- operative: microfracture, osteochondral grafting (autograft or allograft), autologous chondrocyte implantation

**Osteomyelitis**

**Treatment**

<table>
<thead>
<tr>
<th>Acute Osteomyelitis</th>
<th>Chronic Osteomyelitis</th>
</tr>
</thead>
</table>
| IV antibiotics; started empirically and adjusted after obtaining blood and aspirate cultures ± surgery for abscess | Surgical debridement
|                                                                                   | Antibiotics: both local (e.g. antibiotic beads) and systemic (IV)                      |

**Septic Joint**

**Etiology**
- most commonly caused by *Staphylococcus aureus* in adults
- consider coagulase-negative *Staphylococcus* in patients with prior joint replacement
- consider *Neisseria gonorrhoeae* in sexually active adults
- most common route of infection is hematogenous
- risk factors: age >80 yr, DM, RA, prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, alcoholism, previous intra-articular corticosteroid injection

**Clinical Presentation**
- inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

**Investigations**
- x-ray (to rule out fracture, tumour, metabolic bone disease), ESR, CRP, WBC, blood cultures
- joint aspirate: WBC >80,000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level < blood glucose level, no crystals, positive Gram stain results
- listen for heart murmur (to rule out infective endocarditis)

**Treatment**
- IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
- for small joints: needle aspiration, serial if necessary until sterile
- for major joints such as knee, hip, or shoulder: urgent decompression and surgical drainage

**Shoulder**

**Shoulder Dislocation**

**Prognosis**
- recurrence rate depends on age of 1st dislocation: <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4%

**Specific Complications**
- rotator cuff or capsular tear, shoulder stiffness
- injury to axillary nerve/artery, brachial plexus
- recurrent/reduced dislocation (most common complication)

**Investigations**
- anterior dislocation x-rays (AP, trans-scapular, axillary views)
- posterior dislocation x-rays (AP, trans-scapular, axillary) or CT scan
## Table 6. Anterior and Posterior Shoulder Dislocation

<td>Cunningham’s method: low risk, low pain; if not successful try above methods</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Obtain post-reduction x-rays</td>
<td>Obtain post-reduction x-rays</td>
</tr>
<tr>
<td></td>
<td>Check post-reduction NVS</td>
<td>Check post-reduction NVS</td>
</tr>
<tr>
<td></td>
<td>Sling x 3 wk (avoid abduction and ext. rotation), followed by shoulder rehabilitation (dynamic stabilizer strengthening)</td>
<td>Sling in abduction and external rotation x 3 wk, followed by shoulder rehabilitation (dynamic stabilizer strengthening)</td>
</tr>
</tbody>
</table>

**Factors Causing Shoulder Instability**
- Shallow glenoid
- Loose capsule
- Ligamentous laxity

**Frequency of Dislocations:**
- Anterior shoulder > Posterior shoulder
- Posterior hip > Anterior hip

The glenohumeral joint is the most commonly dislocated joint in the body since stability is sacrificed for motion.
Rotator Cuff Disease

- rotator cuff consists of 4 muscles (Table 7) that act to stabilize humeral head within the glenoid fossa (see Figure 14)

Table 7. Rotator Cuff Muscles

<table>

SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

Etiology
- impingement: “painful arc syndrome”, compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of acromion, AC joint and CA ligament leads to bursitis, tendonitis and if left untreated, can lead to rotator cuff thinning and tear
- anything that leads to a narrow subacromial space
  - glenohumeral muscle weakness leading to abnormal motion of humeral head
  - scapular muscle weakness leading to abnormal motion of acromion
  - acromial abnormalities such as congenital narrow space or osteophyte formation

Clinical Features
- night pain and difficulty sleeping on affected side
- pain worse with active motion
- weakness and loss of range of motion especially between 90°-130° (e.g. trouble with overhead activities)
- tenderness to palpation over greater tuberosity
- rule out bicep tendinosis: Speed and Yergason’s tests; SLAP lesion: O’Brien’s test

</tbody>
</table>

**Figure 15. Rotator cuff tests**

**Investigations**
- x-rays: AP view may show high riding humerus relative to glenoid, evidence of chronic tendonitis
- MRI: coronal/sagittal oblique and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geyser sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: see full thickness tear, difficult to assess partial thickness tears

**Treatment and Prognosis**
- mild (“wear”)
  - treatment is non-operative (physiotherapy, NSAIDs)
- moderate (“tear”)
  - non-operative treatment ± steroid injection
- severe (“repair”)
  - impingement that is refractory to 2-3 mo physio and 1-2 injections
  - may require arthroscopic or surgical repair, i.e. acromioplasty, rotator cuff repair

**Screening Out Rotator Cuff Tears**
- No night pain (SN 87.7%)
- No painful arc (SN 97.5%)
- No impingement signs (SN 97.2%)
- No weakness

Returning to the bedside: Using the history and physical examination to identify rotator cuff tears.
*JAM Geri Soc* 2000;48:1633-1637

**Ruling in Rotator Cuff Tears – 98% probability of rotator cuff tear if all 3 of the following are present:**
- Supraspinatus weakness
- External rotation weakness
- Positive impingement sign(s)

Acromioclavicular Joint Pathology

- 2 main ligaments attach clavicle to scapula: AC and CC ligaments

Mechanism
- fall onto shoulder with adducted arm (fall onto tip of shoulder)

Clinical Features
- palpate step deformity between distal clavicle and acromion (with dislocation)
- pain with adduction of shoulder and/or palpation over AC joint
- limited ROM

Investigations
- x-rays: AP, Zanca view (10-15° cephalic tilt), axillary ± stress views (10 lb weight in patient’s hand)

Treatment
- non-operative (most common): sling 1-3 wk, ice, analgesia, rehabilitation
- operative
  - indications: AC and CC ligaments are both torn and/or clavicle displaced posteriorly
  - procedure: excision of lateral clavicle with AC/CC ligament reconstruction

Clavicle Fracture

- incidence: proximal (5%), middle (80%), or distal (15%) third of clavicle
- common in children (unites rapidly without complications)

Mechanism
- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

Clinical Features
- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

Treatment
- evaluate neurovascular status of entire upper limb
- medial and middle third clavicle fractures
  - figure-of-eight sling x 1-2 wk
  - early ROM and strengthening once pain subsides
  - if ends overlap >2 cm consider ORIF
- distal third clavicle fractures
  - undisplaced (with ligaments intact): sling x 1-2 wk
  - displaced (CC ligament injury): ORIF

Specific Complications (see General Fracture Complications, OR6)
- cosmetic bump usually only complication
- shoulder stiffness, weakness with repetitive activity
- pneumothorax, brachial plexus injuries and subclavian vessel (all very rare)

Frozen Shoulder (Adhesive Capsulitis)

Definition
- disorder characterized by progressive pain and stiffness of the shoulder usually resolving spontaneously after 18 mo
Mechanism
- primary adhesive capsulitis
  - idiopathic, usually associated with diabetes mellitus
  - usually resolves spontaneously in 9-18 mo
- secondary adhesive capsulitis
  - due to prolonged immobilization
  - shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling
  - following myocardial infarction, stroke, shoulder trauma
  - poorer outcomes

Clinical Features
- gradual onset (weeks to months) of diffuse shoulder pain with:
  - decreased active and passive ROM
  - pain worse at night and often prevents sleeping on affected side
  - increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

Investigations
- x-rays may be normal, or may show demineralization from disease

Treatment
- Freezing Phase
  - active and passive ROM (physiotherapy)
  - NSAIDs and steroid injections if limited by pain
- Thawing Phase
  - manipulation under anaesthesia and early physiotherapy
  - arthroscopy for debridement/decompression

Humerus

Proximal Humeral Fracture

Mechanism
- young: high energy trauma (MVC)
- elderly: FOOSH from standing height in osteoporotic individuals

Clinical Features
- proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm later

Investigations
- test axillary nerve function (deltoid contraction and skin over deltoid)
- x-rays: AP, trans-scapular, axillary are essential
- CT scan: to evaluate for articular involvement and fracture displacement

Classification
- Neer classification is based on 4 fracture fragments (see Neer Classification sidebar)
  - displaced: displacement >1 cm and/or angulation >45°
  - the Neer system regards displacement, not the fracture line, as meeting criteria for a ‘part’ in the classification scheme
  - ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

Treatment
- treat osteoporosis if needed
- non-operative (nondisplaced or minimally displaced)
  - broad arm sling immobilization (nondisplaced): begin ROM in 7-10 d to prevent stiffness
  - closed reduction (minimally displaced) with sling immobilization x 2 wk, gentle ROM
- operative
  - ORIF (anatomic neck fractures, displaced, associated dislocated glenohumeral joint)
  - hemiarthroplasty may be necessary, especially in elderly

Specific Complications (see General Fracture Complications, OR6)
- AVN, axillary nerve palsy, malunion, post-traumatic arthritis

Conditions Associated with an Increased Incidence of Adhesive Capsulitis
- Prolonged immobilization (most significant)
- Female gender
- Age >49 yr
- Diabetes mellitus (5x)
- Cervical disc disease
- Hyperthyroidism
- Stroke
- Myocardial infarction
- Trauma and surgery

Anatomic neck fractures disrupt blood supply to the humeral head and AVN of the humeral head may ensue.
Humeral Shaft Fracture

Mechanism
- direct blows/MVC (most common), FOOSH, twisting injuries, metastases (in elderly)

Clinical Features
- pain, swelling, ± shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment dorsum of hand

Investigations
- x-rays: AP and lateral radiographs of the humerus including the shoulder and elbow joints

Treatment
- in general, humeral shaft fractures are treated non-operatively
- non-operative (most common)
  - ± reduction; can accept deformity due to compensatory range of motion of shoulder
  - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
  - indications: open fracture, neurovascular injury, unacceptable fracture alignment, polytrauma, segmental fracture, pathological fracture, “floating elbow” (simultaneous unstable humeral and forearm fractures), intra-articular
  - ORIF: plating (most common), intramedullary rod insertion, external fixation

Specific Complications (see General Fracture Complications, OR6)
- radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
- non-union: most frequently seen in middle 1/3
- decreased ROM
- compartment syndrome

Elbow

Supracondylar Fracture

- most common in pediatric population (peak age ~7 yr old), rarely seen in adults
- fracture of the distal 1/3 of humerus just proximal to capitulum and trochlea, usually transverse
- AIN injury commonly associated with extension type

Mechanism
- >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

Clinical Features
- pain, swelling, point tenderness
- neurovascular injury: assess median and radial nerve, radial artery (check radial pulse)

Investigations
- x-rays: AP, lateral of elbow (Figure 17)
  - assess for anterior fat pad (‘sail sign’) or the presence of a posterior fat pad representative of an occult fracture (Figure 18)

Treatment
- reduction indications: evidence of arterial obstruction, unacceptable angulation, displaced (>50%)
- non-operative
  - nondisplaced: long arm plaster slab in 90° flexion x 3 wk
- operative
  - indications: displaced, vascular injury, open fracture
  - requires percutaneous pinning followed by limb cast with elbow flexed >90°
  - in adults, ORIF is necessary

Specific Complications (see General Fracture Complications, OR6)
- stiffness is most common
- brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkman’s ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)
### Radial Head Fracture

- a common fracture of the upper limb in young adults

**Mechanism**
- FOOSH with elbow extended and forearm pronated

**Clinical Features**
- marked local tenderness on palpation over radial head (lateral elbow)
- decreased ROM at elbow, mechanical block to forearm pronation and supination
- pain on pronation/supination

**Investigations**
- x-ray: enlarged anterior fat pad (“sail sign”) or the presence of a posterior fat pad indicates occult radial head fractures (Figure 18)

**Table 10. Classification and Treatment of Radial Head Fractures**

<table>

<td>3</td>
<td>Comminuted fracture</td>
<td>Radial head excision ± prosthesis</td>
</tr>
<tr>
<td>4</td>
<td>Comminuted fracture with posterior elbow dislocation</td>
<td>Radial head excision ± prosthesis</td>
</tr>
</tbody>
</table>

**Specific Complications** (see General Fracture Complications, OR6)
- myositis ossificans
- recurrent instability (if medial collateral ligament injured and radial head excised)

### Olecranon Fracture

**Mechanism**
- direct trauma to posterior aspect of elbow (fall onto the point of the elbow)

**Clinical Features**
- ± loss of active extension due to avulsion of triceps tendon

**Treatment**
- undisplaced (<2 mm, stable): cast x 10–14 d (elbow in 90° flexion) then gentle ROM
- displaced: ORIF (plate and screws or tension band wiring) and early ROM if stable

### Elbow Dislocation

- third most common joint dislocation after shoulder and patella
- usually the radius and ulna are dislocated together, or the radius head dislocates and the ulna remains (“Monteggia”)
- anterior capsule and collateral ligaments disrupted

**Mechanism**
- elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
- most commonly occurs in young people (5–25 yr) in sporting events or high speed MVCs
- 90% are posterior/posterolateral, anterior are rare and usually devastating

**Clinical Features**
- elbow pain, swelling, deformity
- flexion contracture
- ± absent radial or ulnar pulses

**Treatment**
- assess neurovascular status before reduction: brachial artery, median and ulnar nerves (can become entrapped during manipulation)
- closed reduction under conscious sedation (post-reduction x-rays required)
- Parvini’s method: patient lies prone with arm hanging down; apply gentle traction downwards on wrist, as olecranon slips distally, gently lift up the arm at elbow to reduce joint
- long-arm splint with forearm in neutral rotation and elbow in 90° flexion
- early ROM (<2 wk)

**Specific Complications** (see General Fracture Complications, OR6)
- stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
- recurrent instability uncommon

---

Terrible Triad
- Radial head fracture
- Coronoid fracture
- Elbow dislocation

To avoid stiffness do not immobilize elbow joint >2-3 wk.

Anterior fat pad

Posterior fat pad

Terrible Triad
- Radial head fracture
- Coronoid fracture
- Elbow dislocation

Anterior Humeral Line
Radio-Capitellar Line
Capitellum
Radial Head

Figure 19. Lateral view of elbow

Elbow Dislocation
The radio-capitellar line refers to an imaginary line along the longitudinal axis of the radius that passes through the centre of the capitellum regardless of the degree of elbow flexion. If the radio-capitellar line does not pass through the centre of the capitellum a dislocation should be suspected.

The anterior humeral line refers to an imaginary line drawn along the anterior surface of the humeral cortex that passes through the middle third of the capitellum when extended inferiorly. In sublux supracondylar fractures the anterior humeral line is disrupted, typically passing through the anterior third of the capitellum.
**Epicondylitis**

- lateral epicondylitis = "tennis elbow", inflammation of the common extensor tendon as it inserts into the lateral epicondyte
- medial epicondylitis = "golfer's elbow", inflammation of the common flexor tendon as it inserts into the medial epicondyte

**Mechanism**
- repeated or sustained contraction of the forearm muscles

**Clinical Features**
- point tenderness over humeral epicondyle and/or distal to it
- pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
- generally a self-limited condition, but may take 6-18 mo to resolve

**Treatment**
- rest, ice, NSAIDs
- use brace/strap
- physiotherapy, stretching and strengthening
- corticosteroid injection
- surgery: percutaneous or open release of common tendon from epicondyle (only after 6-12 mo of conservative therapy)

---

**Radius and Ulna Fracture**

**Mechanism**
- commonly a FOOSH or high-energy direct blow
- fractures usually accompanied by displacement due to high force

**Investigations**
- x-ray: 1) AP and lateral of forearm; 2) AP, lateral, oblique of elbow and wrist
- CT if fracture is close to joint

**Treatment**
- goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
- ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

**Complications** (see General Fracture Complications, OR6)
- soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted

---

**Monteggia Fracture**

- more common and better prognosis in the pediatric age group when compared to adults

**Definition**
- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury (Figure 20)

**Mechanism**
- direct blow on the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

**Clinical Features**
- decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

**Treatment**
- adults: ORIF of ulna with indirect radius reduction in 90% of patients
- splint and early post-op ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 6 wk
- pediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

---

**Figure 20. Monteggia fracture**

In all isolated ulna fractures, assess proximal radius to rule out a Monteggia fracture.
Specific Complications (see General Fracture Complications, OR6)
- PIN: most common nerve injury, especially with posterior approach to the radius fixation
- radial head instability/redislocation
- radioulnar synostosis

Nightstick Fracture

Definition
- isolated fracture of ulna without dislocation of radial head

Mechanism
- direct blow to forearm (e.g. holding arm up to protect face)

Treatment
- non-displaced: below elbow cast (x 10 d) followed by forearm brace (~8 wk)
- displaced: ORIF if >50% shaft displacement or >10° angulation

Galeazzi Fracture

Definition
- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis
- 3x more common than Monteggia fracture

Mechanism
- hand FOOSH with axial loading of pronated forearm

Investigations
- x-rays
  - shortening of distal radius >5 mm relative to the distal ulna
  - widening of the DRUJ space on AP
  - dislocation of radius with respect to ulna on true lateral

Treatment
- ORIF of radius; afterwards assess DRUJ stability by balloting distal ulna relative to distal radius
- if DRUJ is stable and reducible, splint for 10-14 d with early ROM encouraged
- if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 6 wk

Wrist

Colles’ Fracture

Definition
- extra-articular transverse distal radius fracture (about 2 cm proximal to the radiocarpal joint) with dorsal displacement ± ulnar styloid fracture

Epidemiology
- most common fracture in those >40 yr, especially in women and those with osteoporotic bone

Mechanism
- FOOSH

Clinical Features
- “dinner fork” deformity (Figures 23 and 24)
- swelling, ecchymoses, tenderness

Investigations
- x-ray: AP and lateral wrist

Treatment
- goal is to restore radial height, radial inclination (22°), volar tilt (11°) as well as DRUJ stability and useful forearm rotation
- closed reduction (think opposite of the deformity):
  - hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
  - closed reduction: 1) traction with extension (exaggerate injury), 2) traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
  - dorsal slab/below elbow cast for 5-6 wk
  - x-ray x 1 wk for 3 wk and at cessation of immobilization to ensure reduction is maintained
  - obtain post-reduction films immediately; repeat reduction if necessary, consider external fixation or ORIF if failure of adequate closed reduction
Smith’s Fracture

Definition
• volar displacement of the distal radius (i.e. reverse Colles’ fracture)

Mechanism
• fall onto the back of the flexed hand

Treatment
• usually unstable and needs ORIF
• if patient is poor operative candidate, may attempt non-operative treatment
• closed reduction with hematoma block (reduction opposite of Colles’)
• long-arm cast in supination x 6 wk

Complications of Wrist Fractures

• most common complications are poor grip strength, stiffness, and radial shortening
• distal radius fractures in individuals <40 yr of age are usually highly comminuted and are likely to require ORIF
• 80% have normal function in 6-12 mo

Scaphoid Fracture

Epidemiology
• common in young men; not common in children or in patients beyond middle age
• most common carpal bone injured
• may be associated with other carpal or wrist injuries (e.g. Colle’s fracture)

Mechanism
• FOOSH: impaction of scaphoid on distal radius, most commonly resulting in a transverse fracture through the middle/waist (50%), distal (38%), or proximal (12%) scaphoid

Clinical Features
• pain with wrist movement
• tenderness in the anatomical "snuff box", over scaphoid tuber, and pain with long axis compression into scaphoid
• usually undisplaced

Investigations
• x-ray: PA, lateral, scaphoid views with wrist extension and ulnar deviation x 2 wk
• ± CT or MRI
• bone scan rarely used
• note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture. If x-ray still negative order CT or MRI

Treatment
• early treatment critical for improving outcomes
• non-displaced (<1 mm displacement/<15° angulation): long-arm thumb spica cast x 4 wk then short arm cast until radiographic evidence of healing is seen (2-3 mo)
• displaced: ORIF with headless/countersink compression screw is the mainstay treatment, or percutaneous K-wire fixation (uncommon) (Figure 26)
Specific Complications (see General Fracture Complications, OR6)
- most common: non-union/mal-union (use bone graft from iliac crest or distal radius with fixation to heal)
- AVN of the proximal fragment
- delayed union (recommend surgical fixation)

Prognosis
- fractures of the proximal third of the scaphoid have 70% rate of non-union or AVN
- waist fractures have healing rates of 80-90%
- distal third fractures have healing rates close to 100%

Hand
- see Plastic Surgery, PL22

Cervical Spine

General Principles
- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
- nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

The proximal pole of the scaphoid receives as much as 100% of its arterial blood supply from the radial artery that enters at the distal pole. A fracture through the proximal third disrupts this blood supply and results in a high incidence of AVN/non-union.
Special Testing
- Compression test: pressure on head worsens radicular pain
- Distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain

X-Rays for C-Spine
- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- Lateral
  - Vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
  - Angulation: between adjacent vertebral bodies (>11° is abnormal)
  - Disc or facet joint widening
  - Anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- Oblique: evaluate pedicles and intervertebral foramen
- ± Swimmer’s view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± Lateral flexion/extension view: evaluate subluxation of cervical vertebrae

Differential Diagnosis of C-Spine Pain
- Neck muscle strain, cervical spondylosis, cervical stenosis, rheumatoid arthritis (spondylitis), traumatic injury, whiplash, myofascial pain syndrome

C-Spine Injury
- See Neurosurgery, NS34

Thoracolumbar Spine

General Principles
- Spinal cord terminates at conus medullaris (L1)
- Individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)

Special Tests
- Straight leg raise: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- Lasegue maneuver: dorsiflexion of foot during straight leg raise makes symptoms worse or, if leg is less elevated, dorsiflexion will bring on symptoms
- Femoral stretch test: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in lumbar region, buttock, or posterior thigh

*Unreliable
Differential Diagnosis of Back Pain
1. mechanical or nerve compression (>90%)
   - degenerative (disc, facet, ligament)
   - peripheral nerve compression (disc herniation)
   - spinal stenosis (congenital, osteophyte, central disc)
   - cauda equina syndrome
2. others (<10%)
   - neoplastic (primary, metastatic, multiple myeloma)
   - infectious (osteomyelitis, TB)
   - metabolic (osteoporosis)
   - traumatic fracture (compression, distraction, translation, rotation)
   - spondyloarthropathies (ankylosing spondylitis)
   - referred (aorta, renal, ureter, pancreas)

DEGENERATIVE DISC DISEASE
- loss of vertebral disc height with age results in:
  - bulging and tears of annulus fibrosus
  - change in alignment of facet joints
  - osteophyte formation
- can cause back-dominant pain
- management
  - non-operative
    - staying active with modified activity
    - back strengthening
    - NSAIDs
    - do not treat with opioids; no proven efficacy of spinal traction or manipulation
  - operative – rarely indicated
    - decompression ± fusion
    - no difference in outcome between non-operative and surgical management at 2 yr

SPINAL STENOSIS
- definition: narrowing of spinal canal <10 mm
- etiology: congenital (idiopathic, osteoporosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylitis, Paget’s disease, trauma)
- clinical features
  - ± bilateral back and leg pain
  - neurogenic claudication (see Table 16)
  - ± motor weakness
  - normal back flexion; difficulty with back extension
- investigations: CT/MRI reveals narrowing of spinal canal, but gold standard = CT myelogram
- treatment
  - non-operative: vigorous physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
  - operative: decompression surgery if conservative methods failed >6 mo

Table 16. Differentiating Claudication

Figure 30. Approach to back pain

MECHANICAL BACK PAIN
- definition: back pain NOT due to prolapsed disc or any other clearly defined pathology
- clinical features
  - dull backache aggravated by activity
  - morning stiffness
  - no neurological signs
- treatment: symptomatic (analgesics, physiotherapy)
- prognosis: symptoms may resolve in 4-6 wk, others become chronic

LUMBAR DISC HERNIATION
- definition: tear in annulus fibrosus allows protrusion of nucleus pulposus causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
- etiology: usually a history of flexion-type injury
- clinical features
  - back dominant pain (central herniation) or leg dominant pain (lateral herniation)
  - tenderness between spines at affected level
  - muscle spasm ± loss of normal lumbar lordosis
  - neurological disturbance is segmental and varies with level of central herniation
    - motor weakness (L4, L5, S1)
    - diminished reflexes (L4, S1)
    - diminished sensation (L4, L5, S1)
  - +ve straight leg raise
  - +ve Lasegue test
  - bowel or bladder symptoms, decreased rectal tone suggests cauda equina syndrome due to central disc herniation – surgical emergency
- investigations: MRI, consider a post void residual volume to check for urinary retention
- treatment
  - symptomatic
    - extension protocol (physiotherapy)
    - NSAIDs
  - 90% resolve in 3 mo. Surgical discectomy reserved for progressive neurological deficit, failure of symptoms to resolve within 3 mo, or cauda equina syndrome due to central disc herniation

SPONDYLOLYSIS
- definition: defect in the pars interarticularis with no movement of the vertebral bodies
- etiology
  - trauma: gymnasts, weightlifters, backpackers, loggers, labourers
- clinical features: activity-related back pain, pain with unilateral extension (Michelis’ test)
- investigations
  - oblique x-ray: “collar” break in the “Scottie dog’s” neck
  - bone scan
  - CT scan
- treatment: activity restriction, brace, stretching exercise

SPONDYLOLISTHESIS
- definition: defect in pars interarticularis causing a forward slip of one vertebra on another usually at L5-S1, less commonly at L4-5
- etiology: congenital (children), degenerative (adults), traumatic, pathological, teratogenic
- clinical features: lower back pain radiating to buttocks

MRI abnormalities (e.g. spinal stenosis, disc herniation) are quite common in both asymptomatic and symptomatic individuals and are not necessarily an indication for intervention without clinical correlation.

Specific Complications
- May present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

Pelvis

Pelvic Fracture

Mechanism
- Young: high energy trauma, either direct or by force transmitted longitudinally through the femur
- Elderly: fall from standing height, low energy trauma
- Lateral compression (most common), vertical shear, or anteroposterior compression fractures

Clinical Features
- Local swelling, tenderness
- Deformity of lower extremity
- Pelvic instability

Investigations
- X-ray: AP pelvis, inlet and outlet views, Judet views (obturatory and iliac oblique for acetabular fracture)
  - 6 cardinal radiographic lines of the acetabulum: ilioischial line, iliopectineal line, tear drop, roof, posterior rim, anterior rim
- CT scan useful for evaluating posterior pelvic injury and acetabular fracture

Classification

</tbody>
</table>

Treatment
- ABCDEs
- Assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
  - If involved, the fracture is considered an open fracture
- Stable fractures: non-operative treatment, protected weight bearing
- Emergency management
  - IV fluids/blood
  - Pelvic binder/sheeting
  - External fixation vs. emergent angiography/embolization
  - Laparotomy (if FAST/DPL positive)
- Indications for operative treatment
  - Unstable pelvic ring injury
  - Disruption of anterior and posterior SI ligament
  - Symphysis diastasis > 2.5 cm
  - Vertical instability of the posterior pelvis

Possible Radiological Findings:
- Pubic rami fractures: superior/inferior
- Pubic symphysis diastasis: common in AP compression (N=5 mm)
- Sacral fractures: common in lateral compression
- SI joint diastasis: common in AP compression (N=1-4 mm)
- Disrupted anterior column (ilipectineal line) or posterior column (ilioischial line)
- “Teardrop” displacement: acetabular fracture
- Iliac, ischial avulsion fractures
- Displacement of the major fragment: superior (VS), open book (APC), bucket handle (LC)
Specific Complications (see General Fracture Complications, OR6)
- hemorrhage (life-threatening)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunction
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high risk of DVT/PE

Hip

Hip Dislocation
- full trauma survey (see Emergency Medicine, Initial Patient Assessment/Management, ER2)
- examine for neurovascular injury PRIOR to open or closed reduction
- reduce hip dislocations ASAP (ideally within 6 h) to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- also see Hip Dislocation after THA, OR28

ANTERIOR HIP DISLOCATION
- mechanism: posteriorly directed blow to knee with hip widely abducted
- clinical features: shortened, abducted, externally rotated limb
- treatment
  - closed reduction under conscious sedation/GA
  - post-reduction CT to assess joint congruity

POSTERIOR HIP DISLOCATION
- most frequent type of hip dislocation
- mechanism: severe force to knee with hip flexed and adducted
  - e.g. knee into dashboard in motor vehicle collision (MVC)
- clinical features: shortened, adducted and internally rotated limb
- treatment
  - closed reduction under conscious sedation/GA only if associated femoral neck fracture
  - ORIF if unstable, intra-articular fragments or posterior wall fracture
  - post-reduction CT to assess joint congruity and fractures
  - if reduction is unstable, put in traction x 4-6 wk

CENTRAL HIP DISLOCATION (rare)
- traumatic injury where femoral head is pushed medially through acetabulum

COMPLICATIONS FOR ALL HIP DISLOCATIONS
- post-traumatic osteoarthritis
- AVN of femoral head
- fracture of femoral head, neck, or shaft
- sciatic nerve palsy in 25% (10% permanent)
- HO
- thromboembolism – DVT/PE

Hip Fracture

General Features
- acute onset of hip pain
- unable to weight-bear
- shortened and externally rotated leg
- painful ROM

X-Ray Features of Subcapital Hip Fractures
- Disruption of Shenton’s line (a radiographic line drawn along the upper margin of the obturator foramen, extending along the inferomedial side of the femoral neck)
- Altered neck-shaft angle (normal is 120-130°)
**Table 19. Overview of Hip Fractures**

**Arthritis of the Hip**

**Etiology**
- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders or septic arthritis

**Clinical Features**
- pain (groin, medial thigh) and stiffness aggravated by activity
- morning stiffness >1 h, multiple joint swelling, hand nodules (RA)
- decreased ROM (internal rotation is lost first)
- crepitus
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenberg sign
Investigations
- x-ray
  - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
  - RA: osteopenia, erosion, joint space narrowing, subchondral cysts, symmetric joint space narrowing
- bloodwork: ANA, RF

Treatment
- non-operative: weight reduction, activity modification, physiotherapy, analgesics, walking aids
- operative: realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
- complications with arthroplasty: component loosening, dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy
- arthroplasty is standard of care in most patients with hip arthritis

Hip Dislocation after Total Hip Arthroplasty

Etiology
- THA that is unstable when hip is flexed, adducted and internally rotated or extended and externally rotated (avoid flexing hip >90° or crossing legs for approximately 6 wk after surgery)

Epidemiology
- occurs in 1-4% of primary THA and 10-16% of revision THAs
- risk factors: neurological impairment, post-traumatic arthritis, revision surgery, substance abuse

Treatment
- external abduction splint to prevent hip adduction
- constrained acetabular component for recurrent dislocation if no issue with position of acetabular/femoral implants + knee immobilizer

Complications
- sciatic nerve palsy in 25% (10% permanent)
- HO

Femoral Diaphysis Fracture

Mechanism
- high energy trauma (MVC, fall from height, gunshot wound)
- in children, can result from low energy trauma (spiral fracture)

Clinical Features
- shortened, externally rotated leg (if fracture displaced)
- inability to weight-bear
- often open injury, always a Gustilo III (see Table 4)

Investigations
- AP pelvis, AP/lateral hip, femur, knee

Complications
- hemorrhage requiring transfusion
- fat embolism leading to ARDS
- extensive soft tissue damage
- ipsilateral hip dislocation/fracture
- nerve injury

Treatment
- stabilize patient
- immobilize leg
- ORIF with anterograde or retrograde IM nail, external fixator for unstable patients, open fractures, or highly vascular areas, or plate and screws for open growth plates within 24 h
- early mobilization and strengthening
**Distal Femoral Fracture**

**Mechanism**
- direct high energy force or axial loading
- three types (Figure 38) in addition to classification as intra-articular or extra-articular

**Clinical Features**
- extreme pain
- knee effusion (hemarthrosis)
- shortened, externally rotated leg if displaced

**Treatment**
- ORIF if displaced or intra-articular; may choose to manage nonoperatively if nondisplaced or incomplete fracture
- early mobilization and strengthening

**Complications** (see General Fracture Complications, OR6)
- femoral artery tear
- nerve injury
- extensive soft tissue injury
- angulation deformities

---

**Knee**

**Evaluation of Knee**

**Common Complaints**
- general orthopedic history
- also inquire about common knee symptoms
  - locking: mechanical block to extension
    - torn meniscus/loose body in joint
  - pseudo-locking: limited ROM without mechanical block
    - effusion, muscle spasm after injury, arthritis
  - painful clicking (audible)
    - torn meniscus
  - giving way: instability
    - cruciate ligament or meniscal tear, patellar dislocation

**Special Tests of the Knee**
- **anterior and posterior drawer tests** (see Figure 41)
  - demonstrate ACL and PCL, respectively
    - knee flexed at 90°, foot immobilized, hamstrings released
      - if able to sublux tibia anteriorly (anterior drawer test), then ACL may be torn
      - if able to sublux tibia posteriorly (posterior drawer test), then PCL may be torn
    - anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio
  - **Lachmann test**
    - demonstrates torn ACL
    - hold knee in 10-20° flexion, stabilizing the femur
    - try to sublux tibia anteriorly on femur
    - similar to anterior drawer test, more reliable due to less muscular stabilization
    - for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio
  - **Thessaly test**
    - demonstrates meniscal tear
    - patient stands flat footed on one leg while the examiner provides his or her hands for balance. The patient then flexes the knee to 20° and rotates the femur on the tibia medially and laterally three times while maintaining the 20° flexion
    - positive for a meniscal tear if the patient experiences medial or lateral joint line discomfort.
    - for medial meniscus: 29.67 positive likelihood ratio, 0.11 negative likelihood ratio
    - for lateral meniscus: 23.0 positive likelihood ratio, 0.083 negative likelihood ratio
  - **posterior sag sign**
    - demonstrates torn PCL
    - may give a false positive anterior draw sign
    - flex knees and hips to 90°, hold ankles and knees
    - view from the lateral aspect
      - if one tibia sags posteriorly compared to the other, its PCL is torn

6 Degrees of Freedom of the Knee: Flex. and ext., Ext. and int. rotation, Varus and valgus angulation, Ant. and post. glide, Med. and lat. shift, Compression and distraction

On physical exam of the knee, do not forget to evaluate the hip!
• **pivot shift sign**
  - demonstrates torn ACL
  - start with the knee in extension
  - internally rotate foot, slowly flex knee while palpating and applying a valgus force
  - normal knee will flex smoothly
  - if incompetent ACL, tibia will sublux anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the “pivot”)
  - reverse pivot shift (start in flexion, externally rotate, apply valgus and extend knee) suggests torn PCL
  - composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
  - composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio

• **collateral ligament stress test**
  - palpate ligament for “opening” of joint space while testing
  - with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
  - repeat tests with knee in 20° flexion to relax joint capsule
  - opening only in 20° flexion due to MCL damage only
  - opening in 20° of flexion and full extension is due to MCL, cruciate, and joint capsule damage

• **tests for meniscal tear**
  - joint line tenderness
    - joint line pain when palpated
    - palpate one side at a time and watch patient’s eyes
    - for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio
  - crouch compression test
    - joint line pain when squatting (anterior pain suggests patellofemoral pathology)
  - McMurray’s test useful collaborative information (see Figure 42)
    - with knee in flexion, palpate joint line for painful “pop/click”
    - internally rotate foot, varus stress, and extend knee to test lateral meniscus
    - externally rotate foot, valgus stress, and extend knee to test medial meniscus
    - for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio
  - composite assessment for meniscal tears: 2.7 positive likelihood ratio, 0.4 negative likelihood ratio

**X-Rays**
- AP standing, lateral
- skyline: tangential view with knees flexed at 45° to see patellofemoral joint
- 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
- Ottawa Knee Rules (see *Emergency Medicine*, ER17)

### Cruciate Ligament Tears

- ACL tear much more common than PCL tear

**Table 21. Comparison of ACL and PCL Injuries**

<table>

</tr>
<tr>
<td><strong>Treatment</strong></td>
<td>Stable knee with minimal functional impairment: immobilization 2-4 wk with early ROM and strengthening</td>
<td>Unstable knee or young person/high-demand lifestyle: ligament reconstruction, Posterior sag</td>
</tr>
</tbody>
</table>

**Figure 41. Anterior and posterior drawer test**

**Figure 42. McMurray test**

**Figure 43. T1 MRI of torn ACL and PCL**
**Collateral Ligament Tears**

**Mechanism**
- valgus force to knee = MCL tear
- varus force to knee = LCL tear

**Clinical Features**
- swelling/effusion
- tenderness above and below joint line medially (MCL) or laterally (LCL)
- joint laxity with varus or valgus force to knee
  - laxity with endpoint suggests partial tear
  - laxity with no endpoint suggests a complete tear
- test for other injuries (e.g. O'Donoghue's unhappy triad), common peroneal nerve injury

**Treatment**
- partial tear: immobilization x 2-4 wk with early ROM and strengthening
- complete tear: immobilization at 30° flexion
- multiple ligamentous injuries: surgical repair of ligaments

**Meniscal Tears**

- medial tear much more common than lateral tear

**Mechanism**
- twisting force on knee when it is partially flexed (e.g. stepping down and turning)
- requires moderate trauma in young person but only mild trauma in elderly due to degeneration

**Clinical Features**
- immediate pain, difficulty weight-bearing, instability and clicking
- increased pain with squatting and/or twisting
- effusion (hemarthrosis) with insidious onset (24-48 h after injury)
- joint line tenderness medially or laterally
- locking of knee (if portion of meniscus mechanically obstructing extension)

**Investigations**
- MRI, arthroscopy

**Treatment**
- if not locked: ROM and strengthening (NSAIDs)
- if locked or failed above: arthroscopic repair/partial meniscectomy

**Quadriceps/Patellar Tendon Rupture**

**Mechanism**
- sudden forceful contraction of quadriceps during an attempt to stop
- more common in obese patients and those with pre-existing degenerative changes in tendon
  - DM, SLE, RA, steroid use, renal failure on dialysis

**Clinical Features**
- inability to extend knee or weight-bear
- possible audible "pop"
- patella in lower or higher position with palpable gap above or below patella respectively
- may have an effusion

**Investigations**
- ask patient to straight leg raise
- knee x-ray to rule out patellar fracture
- lateral view: patella alta with patellar tendon rupture, patella baja (infera) with quadriceps tendon rupture

**Treatment**
- nonoperative treatment for incomplete tears with preserved extension of knee
- surgical repair of tendon indicated for complete ruptures
- early surgical repair: better outcomes compared with delayed repair (>6 wk post injury)
- delayed repair complicated by quadriceps contracture, patella migration, and adhesions

**Tissue Sources for ACL Reconstruction**
- Hamstring
- Middle 1/3 patellar tendon (bone-patellar-bone)
- Allograft (e.g. cadaver)
Dislocated Knee

Mechanism
- high energy trauma
- by definition, caused by tears of multiple ligaments

Clinical Features
- classified by relation of tibia with respect to femur
  - anterior, posterior, lateral, medial, rotary
- knee instability
- effusion
- pain
- ischemic limb

Investigations
- x-rays: AP, lateral, skyline
  - associated radiographic findings include tibial plateau fracture dislocations, proximal fibular fractures, and avulsion of fibular head
- ankle brachial index (abnormal if <0.9)
- arteriogram if abnormal vascular exam (such as abnormal pedal pulses)

Treatment
- urgent closed reduction
  - complicated by interposed soft tissue
- assessment of peroneal nerve, tibial artery, and ligamentous injuries
- repair of associated injuries; also may need decompressive fasciotomy especially if vascular repair undertaken
- knee immobilization x 6-8 wk

Specific Complications
- high incidence of associated injuries
  - popliteal artery tear
  - peroneal nerve injury
  - capsular tear
- chronic: instability, stiffness, post-traumatic arthritis

Patella

Patellar Fracture

Mechanism
- direct blow to the patella: fall, MVC (dashboard)
- indirect trauma by sudden flexion of knee against contracted quadriceps

Clinical Features
- marked tenderness
- inability to extend knee or straight leg raise
- proximal displacement of patella
- patellar deformity
- ± effusion/hemarthrosis

Investigations
- x-rays: AP, lateral, skyline
  - consider bipartite patella: congenitally unfused ossification centres with smooth margins on x-ray

Treatment
- goal: restore extensor mechanism with maximal articular congruency
  - non-displaced (step-off <2-3 mm and fracture gap <1-4 mm)
    - straight leg immobilization 1-4 wk with hinged knee brace
    - physiotherapy: quadriceps strengthening when pain has subsided
- displaced: ORIF (>2 mm)
- comminuted: ORIF; may require partial/complete patellectomy
- disrupted extensor mechanism: ORIF

Complications
- Symptomatic wiring
- Hardware failure
- Knee stiffness
- Nonunion
- Infection
Patellar Dislocation

Mechanism
- lateral displacement of patella after contraction of quadriceps against a flexed knee

Risk Factors
- young, female
- obesity
- high-riding patella (patella alta)
- knock-knees (genu valgus)
- Q-angle (quadriceps angle) ≥20° (see Figure 45)
- shallow intercondylar groove
- weak vastus medialis
- tight lateral retinaculum

Clinical Features
- knee catches or gives way with walking
- severe pain, tenderness anteromedially from rupture of capsule
- weak knee extension or inability to extend leg unless patella reduced
- +ve patellar apprehension test
- patient apprehensive when examiner laterally displaces patella
- often recurrent, self-reducing
- concomitant MCL injury

Investigations
- x-rays: AP, lateral, skyline view of patella
- check for fracture of medial patella and lateral femoral condyle

Treatment
- non-operative first
  - knee immobilization x 4-6 wk
  - progressive weight bearing and isometric quadriceps strengthening
  - if recurrent
  - surgical tightening of medial capsule and release of lateral retinaculum, possible tibial tuberosity transfer, or proximal tibial osteotomy

Patellofemoral Syndrome (Chondromalacia Patellae)

Mechanism
- softening, erosion and fragmentation of articular cartilage, predominantly medial aspect of patella
- commonly seen in active young females

Predisposing Factors
- malalignment causing patellar maltracking (Q angle ≥20°, genu valgus)
- post-trauma
- deformity of patella or femoral groove
- recurrent patellar dislocation, ligamentous laxity
- excessive knee strain (athletes)

Clinical Features
- deep, aching anterior knee pain
  - exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting
  - sensation of instability, pseudolocking
  - pain with extension against resistance through terminal 30-40°
  - swelling rare, minimal if present

Investigations
- x-rays: AP, lateral, skyline

Treatment
- non-operative
  - continue non-impact activities
  - NSAIDs
  - physiotherapy: quadriceps strengthening
  - surgical with refractory patients
    - tibial tubercle elevation
    - arthroscopic shaving/debridement
    - lateral release of retinaculum

Patellar Open Reduction and Internal Fixation
- Longitudinal midline excision over patella
- Tension-band wiring fixation
- Preserve patellar bone
- Antibiotic, debridement, early fixation in open fracture
Tibia Plateau Fracture

Mechanism
- axial loading (e.g. fall from height)
- femoral condyles driven into proximal tibia
- can result from minor trauma in osteoporotics

Clinical Features
- lateral fractures more common than medial
- medial fractures require higher energy – often have concomitant vascular injuries
- knee effusion
- inability to bear weight
- swelling

Classification
- Schatzker classification (see sidebar)

Investigations
- x-rays: AP, lateral
- CT: pre-operative planning

Tibial Shaft Fracture

Mechanism
- numerous, including MVC, falls, sporting injuries

Clinical Features
- open vs. closed
- amount of displacement
- neurovascular status
- most commonly fractured long bone
- most common open fracture

Investigations
- x-rays: AP, lateral, skyline

Treatment
- closed
  - minimally displaced: straight leg cast x 4-6 wk with early weight bearing
  - displaced: ORIF with reamed IM nail, plate and screws, or external fixator
- open
  - external fixation or IM nail
  - vascularized coverage of soft tissue defects (often heal poorly)

Specific Complications (see General Fracture Complications, OR6)
- high incidence of neurovascular injury and compartment syndrome
- poor soft tissue coverage

Figure 46. Tibial shaft fracture treated with intramedullary nail and screws
Ankle

Evaluation of Ankle and Foot Complaints

Special Tests
- anterior drawer: examiner attempts to displace the foot anteriorly against a fixed tibia
- talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated by x-ray

X-Ray
- AP, lateral
- mortise view: ankle at 15° of internal rotation
  - gives true view of ankle joint
- joint space should be symmetric with no talar tilt
- Ottawa Ankle Rules should guide use of x-ray (see sidebar); nearly 100% sensitivity
- ± CT to better characterize fractures

Ankle Fracture

Mechanism
- pattern of fracture depends on the position of the ankle when trauma occurs
- generally involves
  - ipsilateral ligamentous tears or transverse bony avulsion
  - contralateral shear fractures (oblique or spiral)
- classification systems
  - Danis-Weber (see below)
  - Lauge-Hansen: based on foot's position and motion relative to leg

Danis-Weber Classification (Figure 47)
- based on level of fibular fracture relative to syndesmosis
- Type A (infra-syndesmotic)
  - pure inversion injury
  - avulsion of lateral malleolus below plafond or torn calcaneofibular ligament
  - ± shear fracture of medial malleolus
- Type B (trans-syndesmotic)
  - external rotation and eversion (most common)
  - ± avulsion of medial malleolus or rupture of deltoid ligament
  - spiral fracture of lateral malleolus starting at plafond
- Type C (supra-syndesmotic)
  - pure external rotation
  - avulsion of medial malleolus or torn deltoid ligament
  - ± posterior malleolus avulsion with posterior fibio-fibular ligament
  - fibular fracture is above plafond (called Maisonneuve fracture if at proximal fibula)
  - frequently tears syndesmosis

Treatment
- undisplaced: non-weight bearing below knee cast
- indications for ORIF
  - any fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
  - most of type B, and all of type C
  - trimalleolar (medial, posterior, lateral) fractures
  - talar tilt >10°
  - medial clear space on x-ray greater than superior clear space
  - open fracture/open joint injury
- high incidence of post-traumatic arthritis
- wrinkle test: skin shows wrinkles, to determine if soft tissue swelling has resolved to an extent to reduce complications

Ligamentous Injuries
- see Figure 48 for ankle ligaments

Medial Ligament Complex (deltoid ligament)
- eversion injury
- usually avulses medial or posterior malleolus and strains syndesmosis
Lateral Ligament Complex (Anterior Talofibular, Calcaneofibular, Posterior Talofibular)

- inversion injury
- ATF most commonly and severely injured if ankle is plantar flexed
- swelling and tenderness anterior to lateral malleolus
- ++ ecchymoses
- ++ ankle anterior drawer
- may have significant medial talar tilt on inversion stress x-ray

Treatment
- microscopic tear (Grade I)
  - rest, ice, compression, elevation (RICE)
- macroscopic tear (Grade II)
  - strap ankle in dorsiflexion and eversion x 4-6 wk
  - physiotherapy: strengthening and proprioceptive retraining
- complete tear (Grade III)
  - below knee walking cast x 4-6 wk
  - physiotherapy: strengthening and proprioceptive retraining
  - surgical intervention may be required if chronic symptomatic instability develops

Foot

Talar Fracture

Mechanism
- axial loading or hyperdorsiflexion (MVC, fall from height)
- 60% of talus covered by articular cartilage
- tenuous blood supply runs distal to proximal along talar neck
  - high risk of AVN with displaced fractures

Investigations
- x-rays: AP, lateral
- CT to better characterize fracture
- MRI can clearly define extent of AVN

Treatment
- undisplaced: non-weight bearing below knee cast x 20-24 wk
- displaced: ORIF (high rate of nonunion, AVN)

Calcaneal Fracture

Mechanism
- axial loading: fall from height onto heels
- 10% of fractures associated with compression fractures of thoracic or lumbar spine
- 5% are bilateral

Physical Examination
- swelling, bruising on heel/sole
- wider, shortened, flatter heel when viewed from behind
- varus heel

Investigations
- x-rays: AP, lateral, oblique (Broden’s view)
- loss of Bohler’s angle
- CT: assess intra-articular extension

Treatment
- closed vs. open reduction is controversial
- non-weight bearing cast x 3 mo with early ROM and strengthening

Achilles Tendonitis

Mechanism
- chronic inflammation from activity or poor-fitting footwear
- may also develop heel bumps (retrocalcaneobursitis)
Physical Examination
• pain, stiffness and crepitus with ROM
• thickened tendon, palpable bump

Treatment
• rest, NSAIDs
• gentle stretching, deep tissue calf massage
• orthotics, open back shoes
• shockwave therapy in chronic tendonitis
• DO NOT inject steroids (risk of tendon rupture)

Achilles Tendon Rupture

Mechanism
• loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
• secondary to chronic tendonitis, steroid injection

Clinical Features
• audible pop, sudden pain with push off movement
• sensation of being kicked in heel when trying to plantar flex
• palpable gap
• apprehensive toe off when walking
• weak plantar flexion strength
• Thompson test: with patient prone, squeezing the calf muscles should passively plantar flex the foot to demonstrate intact Achilles tendon
  • +ve test = no passive plantar flexion = ruptured tendon

Treatment
• low demand or elderly: cast foot in plantar flexion (to relax tendon) x 8-12 wk
• high demand: surgical repair, then cast as above x 6-8 wk

Plantar Fasciitis (Heel Spur Syndrome)

Mechanism
• repetitive strain injury causing microtears and inflammation of plantar fascia
• female: male = 2:1
• common in athletes (especially runners)
• also associated with obesity, DM, seronegative and seropositive arthritis

Clinical Features
• morning pain and stiffness
• intense pain when walking from rest that subsides as patient continues to walk
• swelling, tenderness over sole
• greatest at medial calcaneal tubercle and 1-2 cm distal along plantar fascia
• pain with toe dorsiflexion (stretches fascia)

Investigations
• plain radiographs to rule out fractures
• often see bony exostoses (heel spurs) at insertion of fascia into medial calcaneal tubercle
  (see Figure 49)
• spur is secondary to inflammation, not the cause of pain

Treatment
• rest, ice, NSAIDs, steroid injection
• physiotherapy: stretching, ultrasound, extracorporeal shockwave therapy
• orthotics with heel cup
  • to counteract pronation and disperse heel strike forces
• endoscopic surgical release of fascia in refractory cases
• spur removal is not required

Bunions (Hallux Valgus)

Mechanism
• valgus alignment on 1st MTP (hallux valgus) causes eccentric pull of extensor and intrinsic muscles
• reactive exostosis forms with thickening of the skin creating a bunion
• most often associated with poor-fitting footwear but can be hereditary
• 10x more frequent in women
Clinical Features
- painful bursa over medial eminence of 1st metatarsal head
- pronation (rotation inward) of great toe
- numbness over medial aspect of great toe

Investigations
- x-ray: standing AP/lateral/sesamoid view, non-weight bearing oblique

Treatment
- indications: painful corn or bunion, overriding 2nd toe
- non-operative first
  - properly fitted shoes (low heel) and toe spacer
- surgical: goal is to restore normal anatomy
  - osteotomy with realignment of 1st MTP joint (Chevron Procedure)
  - arthrodesis

Metatarsal Fracture
- as with the hand, 1st, 4th, 5th MT are relatively mobile, while the 2nd and 3rd are fixed (Table 22)
- use Ottawa Foot Rules to determine need for x-ray (see sidebar)

Table 22. Types of Metatarsal Fractures

Pediatric Orthopedics

Fractures in Children
- type of fracture
  - thicker, more active periosteum results in pediatric specific fractures: greenstick, torus (buckle) and plastic (bowing)
  - adults fracture through both cortices
  - epiphyseal growth plate
    - weaker part of bone, susceptible to fractures
    - plate often mistaken for fracture on x-ray and vice versa (x-ray opposite limb for comparison), especially in elbow (see sidebar)
    - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
    - intra-articular fractures have worse consequences in children because they usually involve the growth plate
  - anatomic reduction
    - gold standard with adults
    - may cause limb length discrepancy in children (overgrowth)
    - accept greater angular deformity in children (remodeling minimizes deformity)
  - time to heal
    - shorter in children
- always be aware of the possibility of child abuse
  - make sure stated mechanism compatible with injury
  - high index of suspicion with fractures in non-ambulating children (<1 yr); look for other signs, including x-ray evidence of healing fractures at different sites and different stages of healing
**Stress Fractures**

**Mechanism**
- insufficiency fracture
  - stress applied to a weak or structurally deficient bone
- fatigue fracture
  - repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- tibia is most common site

**Diagnosis and Treatment**
- localized pain and tenderness over the involved bone
- plain films may not show fracture for 2 wk
- bone scan +ve in 12-15 d
- treatment is rest from strenuous activities to allow remodeling (can take several months)

**Evaluation of the Limping Child**
- see Pediatrics, P96

**Epiphyseal Injury**

*Table 23. Salter-Harris Classification of Epiphyseal Injury*

<table>
<thead>
<tr>
<th>SALT(E)R–Harris Type</th>
<th>Description</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>I (Straight through; Stable)</td>
<td>Transverse through growth plate</td>
<td>Closed reduction and cast immobilization (except SCFE – ORIF); heals well, 95% do not affect growth</td>
</tr>
<tr>
<td>II (Above)</td>
<td>Through metaphysis and along growth plate</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>III (Low)*</td>
<td>Through epiphysis to plate and along growth plate</td>
<td>Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate</td>
</tr>
<tr>
<td>IV (Through and through)*</td>
<td>Through epiphysis and metaphysis</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>V (Ram)*</td>
<td>Crush injury of growth plate</td>
<td>High incidence of growth arrest; no specific treatment</td>
</tr>
</tbody>
</table>

* Types III – IV are more likely to cause growth arrest and progressive deformity

**Slipped Capital Femoral Epiphysis (SCFE)**

- type I Salter-Harris epiphyseal injury at proximal hip
- most common adolescent hip disorder, peak incidence at pubertal growth spurt
- risk factors: male, obese, hypothyroid

**Etiology**
- multifactorial
  - genetic: autosomal dominant, blacks > caucasians
  - cartilaginous physis thickens rapidly under growth hormone effects
  - sex hormone secretion, which stabilizes physis, has not yet begun
  - overweight: mechanical stress
  - trauma: causes acute slip

**Clinical Features**
- acute: sudden, severe pain with limp
- chronic: limp with medial knee or anterior thigh pain
- +ve Trendelenburg sign on affected side, due to weakened gluteal muscles
- tender over joint capsule
- restricted internal rotation, abduction, flexion
- Whitman’s sign: with flexion there is an obligate external rotation of the hip
- pain at extremes of ROM

**Investigations**
- x-rays: AP, frog-leg, lateral radiographs
  - posterior and medial slip
  - disruption of Klein’s line (see sidebar)
  - AP view may be normal or show slightly widened growth plate compared with opposite side

**Ossification Centres of the Elbow**

<table>
<thead>
<tr>

</tr>
<tr>
<td>External (lateral) epicondyle</td>
<td>12 yr (± 1 yr)</td>
</tr>
</tbody>
</table>

**Figure 52. Salter-Harris classification**

- SCFE – Klein’s Line
  - On AP view, line drawn along suprolateral border of femoral neck should cross at least a portion of the femoral epiphysis. If it doesn’t, suspect SCFE.
Treatment and Complications
• mild/moderate slip: stabilize physis with pins in current position
• severe slip: ORIF or pin physis without reduction and osteotomy after epiphyseal fusion
• complications: AVN (most common), chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM

Developmental Dysplasia of the Hip
• formerly called congenital dysplasia of the hip
• due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
• spectrum of conditions that lead to hip subluxation and dislocation
  • dislocated femoral head completely out of acetabulum
  • dislocatable head in socket
  • head subluxates out of joint when provoked
  • dysplastic acetabulum, more shallow and more vertical than normal
• painless (if painful suspect septic dislocation)

Physical Examination
• diagnosis is clinical
  • limited abduction of the flexed hip (<50-60°)
  • affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
  • Barlow's test (for dislocatable hip)
    • flex hips and knees to 90° and grasp thigh
    • fully adduct hips, push posteriorly to try to dislocate hips
  • Ortolani's test (for dislocated hip)
    • initial position as above but try to reduce hip with fingertips during abduction
    • positive test: palpable clunk is felt (not heard) if hip is reduced
  • Galeazzi's sign
    • knees at unequal heights when hips and knees flexed
    • dislocated hip on side of lower knee
    • difficult test if child <1 yr
  • Trendelenburg test and gait useful if older (>2 yr)

Investigations
• U/S in first few months to view cartilage (bone is not calcified in newborns)
• follow up radiograph after 3 mo
• x-ray signs: false acetabulum, acetabular index >30°, broken Shenton's line, femoral neck above Hilgenreiner's line, ossification centre outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner's and Perkin's line)

Treatment and Complications
• 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
• 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
• >18 mo: open reduction; pelvic and/or femoral osteotomy
• complications
  • redislocation, inadequate reduction, stiffness
• AVN of femoral head

Legg-Calvé-Perthes Disease (Coxa Plana)
• self-limited AVN of femoral head, presents at 4-10 yr of age
• etiology unknown, 20% bilateral, males > females, 1/10,000
• associations
  • family history
  • low birth weight
  • abnormal pregnancy/delivery
  • history of trauma to affected hip
• key features
  • AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodelling of regenerated bone

Clinical Features
• child with hip pain and limp
• tender over anterior thigh
• flexion contracture: decreased internal rotation and abduction of hip
Investigations
- x-rays
  - may be negative early (if high index of suspicion, move to bone scan or MRI)
  - eventually, characteristic collapse of femoral head (diagnostic)

Treatment
- goal is to preserve ROM and preserve femoral head in acetabulum
- physiotherapy: ROM exercises
- brace in flexion and abduction x 2-3 yr
- femoral or pelvic osteotomy
  - prognosis better in males, <5 yr old, <50% of femoral head involved, abduction >30°
  - 50% of involved hips do well with non-operative treatment
  - complicated by early onset osteoarthritis and decreased ROM

**Osgood-Schlatter Disease**

Mechanism
- repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

Clinical Features
- tender lump over tibial tuberosity
- pain on resisted leg extension
- anterior knee pain exacerbated by jumping or kneeling, relieved by rest

Investigations
- x-rays: fragmentation of the tibial tubercle, ± ossicles in patellar tendon

Treatment
- benign, self-limited condition
- may restrict activities such as basketball or cycling
- flexibility, isometric strengthening exercises

**Congenital Talipes Equinovarus (Club Foot)**

- etiology: intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine growth restriction), may be idiopathic, neurogenic, or syndrome-associated
- fixed deformity
- 3 parts to deformity
  - talipes: talus is inverted and internally rotated
  - equinus: ankle is plantar flexed
  - varus: heel and forefoot are in varus (supinated)
- 1-2/1,000 newborns, 50% bilateral, occurrence M>F, severity F>M

Physical Examination
- examine hips for associated DDH
- examine knees for deformity
- examine back for dysraphism (unfused vertebral bodies)

Treatment
- correct deformities in the following order (Ponseti Technique):
  - forefoot adduction, ankle inversion, equinus
    - change strapping/cast q1-2wk
  - surgical release in refractory case (rare)
    - delayed until 3-4 mo of age
- 3 yr recurrence rate = 5-10%
- mild recurrence common; affected foot is permanently smaller/stiffer than normal foot with calf muscle atrophy

**Scoliosis**

Definition
- lateral curvature of spine with vertebral rotation

Epidemiology
- age: 10-14 yr
- more frequent and more severe in females
Etiology
• idiopathic: most common (90%)
• congenital: vertebrae fail to form or segment
• neuromuscular: UMN or LMN lesion, myopathy
• postural: leg length discrepancy, muscle spasm
• other: osteochondrodystrophies, neoplastic, traumatic

Clinical Features
• ± back pain
• 1º curve where several vertebrae affected
• 2º curves above and below fixed 1º curve to try and maintain normal position of head and pelvis
• asymmetric shoulder height when bent forward
• Adam's test: rib hump when bent forward
• prominent scapulae, creased flank, asymmetric pelvis
• associated posterior midline skin lesions in neuromuscular scolioses
  • café-au-lait spots, dimples, neurofibromas
  • axillary freckling, hemangiomas, hair patches
• associated pes cavus or leg atrophy
• apparent leg length discrepancy

X-Rays
• 3-foot standing, AP, lateral
  • measure curvature: Cobb angle (Figure 55)
  • may have associated kyphosis

Treatment
• based on Cobb angle
  • <20°: observe for changes
  • >20° or progressive: bracing (many types) that halt/slow curve progression but do NOT reverse deformity
  • >40°, cosmetically unacceptable or respiratory problems: surgical correction (spinal fusion)

Bone Tumours
• primary bone tumours are rare after 3rd decade
• metastases to bone are relatively common after 3rd decade

Adapted from: Bucholtz RW and Heckman JD. Rockwood and Green’s Fractures in Adults. Volume 1. Philadelphia: Lippincott Williams & Wilkins, 2001, 558

Diagnosis
• pain, swelling, tenderness, rarely regional adenopathy
• routine x-ray findings
  • location (which bone, diaphysis, metaphysis, epiphysis)
  • size
  • lytic/lucent vs. sclerotic
  • involvement (cortex, medulla, soft tissue)
  • matrix (radiolucent, radiodense or calcified)
  • periosteal reaction
  • margin (geographic vs. permeative)
  • any pathological fracture
  • soft tissue swelling
• malignancy is suggested by rapid growth, warmth, tenderness, lack of sharp definition
• staging should include
  • bloodwork including liver enzymes
  • CT chest
  • bone scan
  • bone biopsy
    • should be referred to specialized centre prior to biopsy
    • classified into benign, benign aggressive, and malignant
  • MRI of affected bone

Red Flags
• Persistent skeletal pain
• Localized tenderness
• Spontaneous fracture
• Enlarging mass/soft tissue swelling

Figure 55. Cobb angle — used to monitor the progression of the scoliotic curve

In structural or fixed scoliosis, bending forwards makes the curve more obvious.

Postural scoliosis can be corrected by correcting the underlying problem.

Figure 56. Codman’s triangle — a radiographic finding in malignancy, where the partially ossified periosteum is lifted off the cortex by neoplastic tissue
### Benign Active Bone Tumours

#### BONE-FORMING TUMOURS

**Osteoid Osteoma**
- peak incidence in 2nd and 3rd decades, M:F = 3:1 (young males)
- tibia and femur most common locations
- not known to metastasize
- radiographic findings: small, round radiolucent nidus (<1 cm) surrounded by dense sclerotic bone (“bull’s-eye”)
- symptoms: produces severe intermittent pain, mostly at night (diurnal prostaglandin production), characteristically relieved by NSAIDs
- treatment: NSAIDs for night pain; surgical resection of nidus

**FIBROUS LESIONS**

**Fibrous Cortical Defect**
- occur in as many as 35% of children, peak incidence between 2-20 yr old, higher prevalence in males
- femur and proximal tibia most common locations, 50% of patients have multiple defects usually bilateral, symmetrical
- radiographic findings: circular/oval, eccentric radiolucency near physis; thin smooth/lobulated well-defined sclerotic margin
- treatment: resolves spontaneously

**Osteochondroma**
- 2nd and 3rd decades, M:F = 1.8:1
- most common of all benign bone tumours ~ 45%
- metaphysis of long bone (usually distal femur, proximal tibia or proximal humerus)
  - radiographic findings: cartilage-capped bony spur on surface of bone (“mushroom” on x-ray)
  - may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
- generally very slow growing and asymptomatic unless impinging on neurovascular structure
  - growth usually ceases when skeletal maturity is reached
- malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)

**Enchondroma** (Figure 57)
- 2nd and 3rd decades
- 50% occur in the small tubular bones of the hand and foot; others in femur, humerus, ribs
- benign cartilagenous growth, develops in medullary cavity
  - single/multiple enlarged rarefied areas in tubular bones
  - lytic lesion with sharp margination and central calcification
- malignant degeneration to chondrosarcoma occurs in 1-2% (pain in absence of pathologic fracture is an important clue)
- not known to metastasize

**CYSTIC LESIONS**

**Unicameral/Solitary Bone Cyst**
- most common cystic lesion
- children and young adults, peak incidence during first 2 decades, M:F = 2:1
- proximal humerus and femur most common
- symptoms: asymptomatic, or local pain; complete pathological fracture (50% presentations) or incidental detection
- radiographic findings: lytic translucent area on metaphyseal side of growth plate, cortex thinned/expanded; well defined lesion
- treatment: aspiration followed by steroid injection; curettage ± bone graft indicated if re-fracture likely

#### Benign Aggressive Bone Tumours

**Giant Cell Tumours/Aneurysmal Bone Cyst/Osteoblastoma** (Figure 58)
- affects patients of skeletal maturity, peak 3rd decade
- osteoblastoma: found in the distal femur, proximal tibia, distal radius, sacrum, tarsal bones, spinae
- giant cell tumour: pulmonary metastases in 3%
- aneurysmal bone cysts: either solid with fibrous/granular tissue, or blood-filled
• **radiographic findings:**
  - giant cell tumour: eccentric lytic lesions, in epiphyses adjacent to subchondral bone; may break through cortex; T2 MRI enhances fluid within lesion (hyper-intense signal)
  - aneurysmal bone cyst: expanded with honeycomb shape
  - osteoblastoma: often nonspecific; calcified central nidus with radiolucent halo and sclerosis
• **symptoms:** local tenderness and swelling, pain may be progressive (giant cell tumours), ± symptoms of nerve root compression (osteoblastoma)
• 15% recur within 2 yr of surgery

**Treatment**
• intralesional curettage + bone graft or cement
• wide local excision of expendable bones

### Malignant Bone Tumours

<table>
<thead>
<tr>
<th>Age</th>
<th>Tumour</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;1</td>
<td>Neuroblastoma</td>
</tr>
<tr>
<td>1-10</td>
<td>Ewing’s of tubular bones</td>
</tr>
<tr>
<td>10-30</td>
<td>Osteosarcoma, Ewing’s of flat bones</td>
</tr>
<tr>
<td>30-40</td>
<td>Reticulum cell sarcoma, fibrosarcoma, periosteal osteosarcoma, malignant giant cell tumour, lymphoma</td>
</tr>
<tr>
<td>&gt;40</td>
<td>Metastatic carcinoma, multiple myeloma, chondrosarcoma</td>
</tr>
</tbody>
</table>

**Osteosarcoma (Figure 59)**
- most frequently diagnosed in 2nd decade of life (60%), 2nd most common primary malignancy in adults
- history of Paget’s disease, previous radiation treatment
- predilection for sites of rapid growth: distal femur (45%), proximal tibia (20%), and proximal humerus (15%)
  - invasive, variable histology; frequent metastases without treatment (lung most common)
- painful symptoms: progressive pain, night pain, poorly defined swelling, decreased ROM
- radiographic findings:
  - characteristic periosteal reaction: Codman’s triangle (Figure 56) or “sunburst” spicule formation (tumour extension into periosteum)
  - destructive lesion in metaphysis may cross epiphyseal plate
- management: complete resection (limb salvage, rarely amputation), neo-adjuvant chemo; bone scan – rule out skeletal metastases, CT chest – rule out pulmonary metastases
- prognosis: 70% (high-grade); 90% (low-grade)

**Chondrosarcoma (Figure 60)**
- primary (2/3 cases)
  - previous normal bone, patient over 40; expands into cortex to give pain, pathological fracture, flecks of calcification
- secondary (1/3 cases)
  - malignant degeneration of pre-existing cartilage tumour such as enchondroma or osteochondroma
  - younger age group and better prognosis than primary chondrosarcoma
- symptoms: progressive pain, uncommonly palpable mass
- radiographic findings: in medullary cavity, irregular “popcorn” calcification
- treatment: unresponsive to chemotherapy, treat with aggressive surgical resection + reconstruction; regular follow-up x-rays of resection site and chest
- prognosis: 10-yr survival 90% low-grade, 20-40% high-grade

**Ewing’s Sarcoma**
- most occur between 5-20 yr old
- florid periosteal reaction in metaphyses of long bone with diaphyseal extension
- metastases frequent without treatment
- signs/symptoms: presents with pain, mild fever, erythema and swelling, anemia, increased WBC, ESR, LDH
- radiographic findings: moth-eaten appearance with periosteal lamellated pattern (“onion-skinning”)
- treatment: resection, chemotherapy, radiation
- prognosis – 70%, worst prognostic factor is distant metastases

**Multiple Myeloma**
- most common primary malignant tumour of bone in adults (~43%)
- 90% occur in people >40 yr old, M:F = 2:1
- signs/symptoms: bone pain (cardinal early symptom), compression/pathological fractures, renal failure, nephritis, high incidence of infections (e.g. pyelonephritis/pneumonia), systemic (weakness, weight loss, anorexia)
- labs: anemia, thrombocytopenia, increased ESR, hypercalcemia
• radiographic findings: multiple, “punched-out” well-demarcated lesions, no surrounding sclerosis, marked bone expansion
• diagnosis:
  ▪ serum/urine immunoelectrophoresis (monoclonal gammopathy)
  ▪ CT-guided biopsy of lytic lesions at multiple bony sites
• treatment: chemotherapy, radiation, surgery for symptomatic lesions or impending fractures – debulking, internal fixation
• prognosis: most 3 yr after diagnosis
  see Hematology, H47

Bone Metastases
• 2/3 from breast or prostate; also consider thyroid, lung, kidney
• usually osteolytic; prostate occasionally osteoblastic
• bone scan for MSK involvement, MRI for spinal involvement may be helpful
• stabilization of impending fractures
  ▪ internal fixation, IM rods
  ▪ bone cement

Head and Neck

**Anatomical Triangles of the Neck**

**Anterior triangle:**
- bounded by anterior border of SCM, midline of neck, and lower border of mandible
- divided into:
  - **submental triangle:** bounded by both anterior bellies of digastric and hyoid bone
  - **digastric triangle:** bounded by anterior and posterior bellies of digastric, and inferior border of mandible
  - **carotid triangle:** bounded by sternocleidomastoid, anterior belly of omohyoid, and posterior belly of digastric
    - contains: tail of parotid, submandibular gland, hypoglossal nerve, carotid bifurcation, and lymph nodes

**Posterior triangle:**
- bounded by posterior border of sternocleidomastoid, anterior border of trapezius, and middle third of clavicle
- divided into:
  - **occipital triangle:** superior to posterior belly of the omohyoid
  - **subclavian triangle:** inferior to posterior belly of omohyoid
  - contains: spinal accessory nerve and lymph nodes

*Virchow node: left lower level IV suprascapular node
**Includes some suprascapular nodes
***Includes pretracheal, precricoid, paratracheal, and perithyroidal nodes

** Differential Diagnoses of Common Presenting Problems **

**Dizziness**

- **True Vertigo**
  - Benign paroxysmal positional vertigo (BPPV)
  - Labyrinthitis
  - Menière's disease
  - Recurrent vestibulopathy
  - Temporal bone fracture
  - Superior semicircular canal dehiscence
  - Ototoxic drug exposure
  - Autoimmune inner ear disease
  - Perilymph fistula
  - Cholesteatoma

- **Central**
  - Cerebrovascular disorders
    - Vertebrobasilar insufficiency
    - Transient ischemic attacks
    - Wallenberg's syndrome
    - Cerebellar infarction
    - Migrainous vertigo
    - Multiple sclerosis
      - Tumours
      - CPA tumours
      - Posterior fossa tumours
      - Glomas tumours
      - Inflammation
      - Meningitis
      - Cerebellar abscess
      - Trauma: cerebellar contusion
      - Toxic: alcohol, hypnotics, drugs

- **Non-Vertiginous**
  - Organic Diseases
    - Cardiac
      - Arrhythmias
      - Aortic stenosis
      - Vasovagal
      - Orthostatic hypotension
      - Anemia
      - Peripheral neuropathy
      - Visual impairment
  - Functional
    - Depression
      - Anxiety
      - Panic disorder
      - Hyperventilation
      - Personality disorder
      - Phobic dizziness

**Common causes in bold**

**Figure 10. Anatomy of the thyroid gland**

**5 Ds of Vertebrobasilar Insufficiency**

- Drop attacks
- Diplopia
- Dysarthria
- Dizziness
- Dysphagia

**Left-sided** enlargement of a suprascapular node (Virchow's node) may indicate an abdominal malignancy

**Right-sided** enlargement may indicate malignancy of the mediastinum, lungs, or esophagus

**Occipital and/or posterior auricular node** enlargement may indicate rubella

**4 Strap Muscles of the Neck**

- Thyrohyoid
- Omohyoid
- Sternothyroid
- Sternohyoid

**Figure 11. Differential diagnosis of dizziness**

True nystagmus and vertigo caused by a peripheral lesion will never last longer than a couple of weeks because of compensation. Central lesions do not compensate, hence nystagmus and vertigo will persist.
### Otalgia

**External Ear**
- Infection
  - Otitis externa
  - Herpes simplex/zoster
  - Auricular cellulitis
- Trauma
  - Frostbite
- Other
  - Neoplasm of external canal
  - Foreign body
  - Cerumen impaction

**Middle/Inner Ear**
- Infection
  - AOM
  - Otitis media with effusion
  - Mastoiditis
  - Myringitis
  - Skull base infections
- Trauma
  - Traumatic perforation
  - Barotrauma
- Other
  - Neoplasm
  - Wegener’s
  - Cholesteatoma

**Referred Pain**
- Infection
  - Tonsillitis
  - Tracheitis
  - Ramsay Hunt syndrome
- Trauma
  - Thyroiditis
  - Cervical arthritis
- Other
  - TMJ syndrome
  - Teeth
  - Trismus
  - Glossopharyngeal neuralgia
  - Neoplasm of oral cavity, larynx, pharynx

*Figure 12. Differential diagnosis of otalgia*

### Hearing Loss

#### Conductive
- External Ear
  - Impacted cerumen
  - Otitis externa
  - Foreign body
  - Keratitis obturans
  - Exostoses, osteomas
  - Tumour of canal
  - Congenital stenosis/microtia
- Middle Ear
  - AOM
  - Otitis media with effusion
  - TM perforation
  - Otosclerosis
  - Tymanosclerosis
  - Eustachian tube dysfunction
  - Cholesteatoma
  - OSScular malformations
  - OSScular discontinuity
  - Hemotympanum
  - Middle ear tumour

#### Sensorineural
- Congenital
- Acquired
  - Genetic
  - Non-syndrome associated
  - Syndrome associated
  - Intrauterine infections (i.e., TORCH)
  - Teratogens
  - Perinatal hypoxia
  - Prematurity/low birth weight
  - Hyperbilirubinemia
  - Presbycusis
  - Noise-induced
  - Menière’s disease
  - Labyrinthitis
  - Sudden SNHL
  - Autoimmune inner ear disease
  - Ototoxic drug exposure
  - Temporal bone trauma
  - Infectious
  - Postmeningitis
  - Syphilis
  - Viral: mumps, CMV, HSV
  - Neoplastic
  - Acoustic neuroma
  - CPA tumours
  - Vascular occlusion/emboli
  - Auditory neuropathy

*Figure 13. Differential diagnosis of hearing loss*
## Tinnitus

### Subjective
- Only heard by patient
  - (common)

### Objective
- Can be heard by others
  - (rare)

#### Neck Mass

![Figure 15. Differential diagnosis of a neck mass](Image)

- **Inflammatory/Infections**
  - Reactive lymphadenopathy
  - TB or atypical mycobacteria
  - Infectious mononucleosis
  - Abscesses
  - Cat scratch fever
  - Sarcoïdosis
  - Kawasaki’s
  - HIV

- **Congenital**
  - Thyroglossal duct cyst
  - Thymus tumour/pleura
  - Pyramidal lobe of thyroid gland
  - Ranula

- **Neoplastic**
  - Branchial cleft cyst
  - Cystic hygroma

- **Malignant**
  - Salivary gland neoplasm
  - Lipoma
  - Fibroma
  - Vascular

- **Benign**
  - Lymphoma
  - Thyroid
  - Sarcoma
  - Salivary gland neoplasm
  - Rhabdomyosarcoma
  - Neuroblastoma

- **Head and neck primary**
  - Infraclavicular primary
  - Leukemia
Hearing

Normal Hearing Physiology

- **Conductive pathway (external auditory canal to cochlea):** air conduction of sound energy down the EAC → vibration of the tympanic membrane (area effect) → sequential vibration of the middle ear ossicles: malleus, incus, stapes (leverage effect) → transmission of amplified vibrations from the stapes footplate in the middle ear to the oval window of the cochlea in the inner ear → pressure differential on cochlear fluid creates movement along the basilar membrane within the cochlea from base to apex

- **Neural pathway (nerve to brain):** basilar membrane vibration stimulates overlying hair cells in the organ of Corti → stimulation of bipolar neurons in the spiral ganglion of the cochlear division of CN VIII → cochlear nucleus → superior olivary nucleus → lateral lemniscus → inferior colliculus → Sylvian fissure of temporal lobe

Types of Hearing Loss

1. **Conductive Hearing Loss (CHL)**
   - the conduction of sound to the cochlea is impaired
   - can be caused by external and middle ear disease

2. **Sensorineural Hearing Loss (SNHL)**
   - due to a defect in the conversion of sound into neural signals or in the transmission of those signals to the cortex
   - can be caused by disease of the cochlea, acoustic nerve (CN VIII), brainstem, or cortex

3. **Mixed Hearing Loss**
   - both a conductive hearing loss and a sensorineural hearing loss are present

Auditory Acuity

- whispered-voice test: mask one ear and whisper into the other
- tuning fork tests (see Table 4) (audiogram is of greater utility)
- sensitivity depends on which tuning fork used (256 Hz, 512 Hz, 1024 Hz)
  - Rinne test:
    - 512 Hz tuning fork is struck and held firmly on mastoid process to test BC. The tuning fork is then placed beside the pinna to test AC
    - If AC > BC → positive Rinne, which is normal
  - Weber test:
    - 512 Hz tuning fork is held on vertex of head and patient states whether it is heard centrally (Weber negative) or is lateralized to one side (Weber right, Weber left)
    - can place vibrating fork on patient’s chin while they clench their teeth, or directly on teeth to elicit more reliable response
    - will only lateralize if difference in hearing loss between ears is >6 dB

Table 4. The Interpretation of Tuning Fork Tests

<table>
<thead>
<tr>
<th>Examples</th>
<th>Weber</th>
<th>Rinne</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal or bilateral sensorineural hearing loss</td>
<td>Central</td>
<td>AC &gt; BC (+) bilaterally</td>
</tr>
<tr>
<td>Right-sided conductive hearing loss, normal left ear</td>
<td>Lateralizes to right</td>
<td>BC &gt; AC (--) right</td>
</tr>
<tr>
<td>Right-sided sensorineural hearing loss, normal left ear</td>
<td>Lateralizes to left</td>
<td>AC &gt; BC (+) bilaterally</td>
</tr>
<tr>
<td>Right-sided severe sensorineural hearing loss or deaf right ear, normal left ear</td>
<td>Lateralizes to left</td>
<td>BC &gt; AC (--) right*</td>
</tr>
</tbody>
</table>

* a vibrating tuning fork on the mastoid stimulates the cochllea bilaterally, therefore in this case, the left cochllea is stimulated by the Rinne test on the right, i.e. a false negative test. These tests are not valid if the ear canals are obstructed with cerumen (i.e. will create conductive loss)

Pure Tone Audiometry

- a threshold is the lowest intensity level at which a patient can hear the tone 50% of the time
- thresholds are obtained for each ear for frequencies 250 to 8000 Hz
- air conduction thresholds are obtained with headphones and measure outer, middle, inner ear, and auditory nerve function
- bone conduction thresholds are obtained with bone conduction oscillators which bypass the outer and middle ear

Degree of Hearing Loss

- determined on basis of the pure tone average (PTA) at 500, 1000, and 2000 Hz
**PURE TONE PATTERNS**

1. **Conductive Hearing Loss (CHL)** (Figure 16B and 16C)
   - BC in normal range
   - AC outside of normal range
   - gap between AC and BC thresholds >10 dB (an air-bone gap)

2. **Sensorineural Hearing Loss (SNHL)** (Figure 16D and 16E)
   - both air and bone conduction thresholds below normal
   - gap between AC and BC <10 dB (no air-bone gap)

3. **Mixed Hearing Loss**
   - both air and bone conduction thresholds below normal
   - gap between AC and BC thresholds >10 dB (an air-bone gap)

**Speech Audiology**

**Speech Reception Threshold (SRT)**
- lowest hearing level at which patient is able to repeat 50% of two syllable words which have equal emphasis on each syllable (spondee words)
- SRT and best pure tone threshold in the 500 to 2000 Hz range (frequency range of human speech) usually agree within 5 dB. If not, suspect a retrocochlear lesion or functional hearing loss
- used to assess the reliability of the pure tone audiometry

**Speech Discrimination Test**
- percentage of words the patient correctly repeats from a list of 50 monosyllabic words
- tested at a level 35 to 50 dB > SRT, therefore degree of hearing loss is taken into account
- patients with normal hearing or conductive hearing loss score >90%
- score depends on extent of SNHL
- rollover effect: a decrease in discrimination as sound intensity increases. Typical of a retrocochlear lesion (e.g. acoustic neuroma)
- investigate further if scores differ more than 20% between ears as asymmetry may indicate a retrocochlear lesion
- used as best predictor of hearing aid response; if patient has HL and problems with word discrimination, hearing aids may not be helpful
Impedance Audiometry

Tymanogram
- the Eustachian tube equalizes the pressure between the external and middle ear
- tympanograms graph the compliance of the middle ear system against a pressure gradient ranging from −400 to +200 mmH₂O
- tympanogram peak occurs at the point of maximum compliance: where the pressure in the external canal is equivalent to the pressure in the middle ear
- normal range: −100 to +50 mmH₂O

Figure 17. Tympanograms

Static Compliance
- volume measurement reflecting overall stiffness of the middle ear system
- normal range: 0.3 to 1.6 cc
- negative middle ear pressure and abnormal compliance indicate middle ear pathology
- in a type B curve, ear canal volumes of greater than 2 cc in children and 2.5 cc in adults indicate TM perforation or presence of a patent ventilation tube

Acoustic Stapedial Reflexes
- stapedius muscle contracts due to loud sound
- acoustic reflex thresholds = 70 to 100 dB greater than hearing threshold; if hearing threshold >85 dB, reflex likely absent
- stimulating either ear causes bilateral and symmetrical reflexes
- for reflex to be present, CN VII must be intact and no conductive hearing loss in monitored ear
- if reflex is absent without conductive or severe sensorineural loss, suspect CN VII lesion
- acoustic reflex decay test = ability of stapedius muscle to sustain contraction for 10 s at 10 dB
  - normally, little reflex decay occurs at 500 and 1000 Hz
  - with cochlear hearing loss, acoustic reflex thresholds are 25 to 60 dB
  - with retrocochlear hearing loss (acoustic neuroma), absent acoustic reflexes or marked reflex decay (>50%) within 5 s

Auditory Brainstem Response (ABR)
- measures neuroelectric potentials (waves) in response to a stimulus in five different anatomic sites (refer to Order of Neural Pathway sidebar on OT9). This test can be used to map the lesion according to the site of the defect
- delay in brainstem response suggests cochlear or retrocochlear abnormalities
- does not require volition or co-operation of patient (therefore of value in children and in malingerers)

Otoacoustic Emissions
- objective test of hearing where a series of clicks is presented to the ear and the cochlea generates an echo which can be measured
- often used in newborn screening
- can be used to uncover normal hearing in malingering patients
- absence of emissions can be due to hearing loss or fluid in the middle ear
Aural Rehabilitation

- dependent on degree of hearing loss, communicative requirements, motivation, expectations, age, and physical and mental abilities
- negative prognostic factors:
  - poor speech discrimination
  - narrow dynamic range (recruitment)
  - unrealistic expectations
- types of hearing aids:
  - BTE: behind the ear (with occlusive mould or open fit which allows natural sound to pass – for milder hearing losses)
  - ITE: in-the-ear, placed in concha
  - ITC: in-the-canal, placed entirely in ear canal
  - CIC: contained-in-canal, placed deeply in ear canal
  - bone conduction – bone-anchored hearing aid (BAHA): attached to the skull
- contralateral routing of signals (CROS)
- assistive listening devices:
  - direct/indirect audio output
  - infrared, FM radio, or induction loop systems
  - telephone, television, or alerting devices
- cochlear implants:
  - electrode is inserted into the cochlea to allow direct stimulation of the auditory nerve
  - for profound bilateral sensorineural hearing loss not rehabilitated with conventional hearing aids
- established indication: post-lingually deafened adults, pre- and post-lingually deaf children

Vertigo

Evaluation of the Dizzy Patient

- vertigo: illusion of rotational, linear, or tilting movement of self or environment
  - vertigo is produced by peripheral (inner ear) or central (brainstem-cerebellum) stimulation
  - it is important to distinguish vertigo from other disease entities that may present with similar complaints of “dizziness” (e.g. cardiovascular, psychiatric, neurological, aging)

Benign Paroxysmal Positional Vertigo (BPPV)

Definition

- acute attacks of transient vertigo lasting seconds to minutes initiated by certain head positions, accompanied by torsional (i.e. rotatory) nystagmus (geotropic = fast phase towards the floor)

Etiology

- due to canalithiasis (migration of free floating otoliths within the endolymph of the semicircular canal) or cupulolithiasis (otolith attached to the cupula of the semicircular canal)
  - can affect each of the 3 semicircular canals, although the posterior canal is affected in >90% of cases
Vertigo

• causes: head injury, viral infection (URTI), degenerative disease, idiopathic
• results in slightly different signals being received by the brain from the two balance organs resulting in sensation of movement

Diagnosis
• history
• positive Dix-Hallpike maneuver (sensitivity 82%, specificity 71%)

Dix-Hallpike Positional Testing (see website for video and illustrations)
• the patient is rapidly moved from a sitting position to a supine position with the head hanging over the end of the table, turned to one side at 45° and neck extended 20° holding the position for 20 s
• onset of vertigo and rotary nystagmus indicate a positive test for the dependent side

Treatment
• reassure patient that process resolves spontaneously
• particle repositioning maneuvers
  • Epley maneuver (performed by MD)
  • Brandt-Daroff exercises (performed by patient)
• surgery for refractory cases
• anti-emetics for nausea/vomiting
• drugs to suppress the vestibular system delay eventual recovery and are therefore not used

Menière’s Disease (Endolymphatic Hydrops)

Definition
• episodic attacks of tinnitus, hearing loss, aural fullness, and vertigo lasting minutes to hours

Proposed Etiology
• inadequate absorption of endolymph leads to endolymphatic hydrops (over accumulation) that distorts the membranous labyrinth

Epidemiology
• peak incidence 40 to 60 yr
• bilateral in 35% of cases

Clinical Features
• vertigo, fluctuating low frequency SNHL, tinnitus, and aural fullness
• ± drop attacks (Tumarkin crisis), ± nausea and vomiting
• vertigo disappears with time (minutes to hours), but hearing loss remains
• early in the disease: fluctuating SNHL
• later stages: persistent tinnitus and progressive hearing loss
• attacks come in clusters and can be debilitating to the patient
• triggers: high salt intake, caffeine, stress, nicotine, and alcohol

Treatment
• acute management may consist of bed rest, antiemetics, antivertiginous drugs [e.g. betahistine (Serc®)], and low molecular weight dextrans (not commonly used)
• long term management may include:
  • medical:
    • low salt diet, diuretics (e.g. hydrochlorothiazide, triamterene, amiloride)
    • Serc® prophylactically to decrease intensity of attacks
  • local application of gentamicin to destroy vestibular end-organ, results in complete SNHL
  • surgical:
    • selective vestibular neurectomy or transtympanic labyrinthectomy
    • vestibular implants have recently been introduced, experimentally
• must monitor opposite ear as bilaterality occurs in 35% of cases

Vestibular Neuronitis

Definition
• acute onset of disabling vertigo often accompanied by nausea, vomiting, and imbalance without hearing loss that resolves over days leaving a residual imbalance that lasts days to weeks

Etiology
• thought to be due to a viral infection (e.g. measles, mumps, herpes zoster)
• ~30% of cases have associated URTI symptoms
• other: microvascular events, diabetes, autoimmune process
• considered to be the vestibular equivalent of Bell’s palsy, sudden hearing loss, and acute vocal cord palsy
Clinical Features
• acute phase:
  ▪ severe vertigo with nausea, vomiting, and imbalance lasting 1 to 5 d
  ▪ irritative nystagmus (fast phase towards the offending ear)
  ▪ patient tends to veer towards affected side
• convalescent phase:
  ▪ imbalance and motion sickness lasting days to weeks
  ▪ spontaneous nystagmus away from affected side
  ▪ gradual vestibular adaptation requires weeks to months
• incomplete recovery likely with the following risk factors: elderly, visual impairment, poor ambulation
• repeated attacks can occur

Treatment
• acute phase:
  ▪ bed rest, vestibular sedatives (Gravol\textsuperscript{®}), diazepam
• convalescent phase:
  ▪ progressive ambulation especially in the elderly
  ▪ vestibular exercises: involve eye and head movements, sitting, standing, and walking

Labyrinthitis
Definition
• acute infection of the inner ear resulting in vertigo and hearing loss

Etiology
• may be serous (viral) or purulent (bacterial)
• occurs as a complication of acute and chronic otitis media, bacterial meningitis, cholesteatoma, and temporal bone fractures
• bacterial: S. pneumoniae, H. influenzae, M. catarrhalis, P. aeruginosa, P. mirabilis
• viral: rubella, CMV, measles, mumps, varicella zoster

Clinical Features
• sudden onset of vertigo, nausea, vomiting, tinnitus, and unilateral hearing loss, with no associated fever or pain
• meningitis is a serious complication

Investigations
• CT head
• if meningitis is suspected: lumbar puncture, blood cultures

Treatment
• treat with IV antibiotics, drainage of middle ear ± mastoidectomy

Acoustic Neuroma (Vestibular Schwannoma)
Definition
• schwannoma of the vestibular portion of CN VIII

Pathogenesis
• starts in the internal auditory canal and expands into cerebellopontine angle (CPA), compressing cerebellum and brainstem
• when associated with type 2 neurofibromatosis (NF2): bilateral acoustic neuromas, café-au-lait skin lesions, and multiple intracranial lesions

Clinical Features
• usually presents with unilateral SNHL or tinnitus
• dizziness and unsteadiness may be present, but true vertigo is rare as tumour growth occurs slowly and thus compensation occurs
• facial nerve palsy and trigeminal (V\textsubscript{1}) sensory deficit (corneal reflex) are late complications

Diagnosis
• MRI with gadolinium contrast is the gold standard
• audiogram (to assess SNHL)
• poor speech discrimination relative to the hearing loss
• stapedial reflex absent or significant reflex decay
• ABR – increase in latency of the 5th wave
• vestibular tests: normal or asymmetric caloric weakness (an early sign)

Treatment
• expectant management if tumour is very small, or in elderly
• definitive management is surgical excision
• other options: gamma knife, radiation
Tinnitus

Definition
• an auditory perception in the absence of an acoustic stimuli, likely related to loss of input to neurons in central auditory pathways and resulting in abnormal firing

History
• subjective vs. objective (see Figure 14, OT7)
• continuous vs. pulsatile (vascular in origin)
• unilateral vs. bilateral
• associated symptoms: hearing loss, vertigo, aural fullness, otalgia, otorrhea

Investigations
• audiology
• if unilateral:
  ▪ ABR, gadolinium enhanced MRI to exclude a retrocochlear lesion
  ▪ CT to diagnose glomus tympanicum (rare)
  ▪ MRI or angiogram to diagnose AVM
• if suspect metabolic abnormality: lipid profile, TSH

Treatment
• if a cause is found, treat the cause (e.g. drainage of middle ear effusion, embolization or excision of AVM)
• with no treatable cause: 50% will improve, 25% worsen, 25% remain the same
• avoid loud noise, ototoxic meds, caffeine, smoking
• tinnitus clinics
• identify situations where tinnitus is most bothersome (e.g. quiet times), mask tinnitus with soft music or “white noise”
• hearing aid if coexistent hearing loss
• tinnitus instrument: combines hearing aid with white noise masker
• trial of tocainamide

Cerumen Impaction

Etiology
• ear wax is a mixture of secretions from ceruminous and pilosebaceous glands, squames of epithelium, dust, and debris

Risk Factors
• hairy or narrow ear canals, in-the-ear hearing aids, cotton swab usage, osteomata

Clinical Features
• hearing loss (conductive)
• ± tinnitus, vertigo, otalgia, aural fullness

Treatment
• cerumenolytic drops (bicarbonate solution, olive oil, glycerine, Cerumenol®, Cerumenex®)
• syringing
• manual debridement (by MD)

Exostoses

Definition
• bony protuberances in the external auditory canal composed of lamellar bone

Etiology
• possible association with swimming in cold water

Clinical Features
• usually an incidental finding
• if large, they can cause cerumen impaction or otitis externa

Treatment
• no treatment required unless symptomatic
Otitis Externa (OE)

Etiology
- bacteria (~90% of OE): Pseudomonas aeruginosa, Pseudomonas vulgaris, E. coli, S. aureus
- fungus: Candida albicans, Aspergillus niger

Risk Factors
- associated with swimming (“swimmer’s ear”)
- mechanical cleaning (Q-tips®), skin dermatitis, aggressive scratching
- devices that occlude the ear canal: hearing aids, headphones, etc.

Clinical Features
- acute:
  - pain aggravated by movement of auricle (traction of pinna or pressure over tragus)
  - otorrhea (sticky yellow purulent discharge)
  - conductive hearing loss ± aural fullness 2º to obstruction of external canal by swelling and purulent debris
  - post-auricular lymphadenopathy
  - complicated OE exists if the pinna and/or the periauricular soft tissues are erythematosus and swollen
- chronic:
  - pruritus of external ear ± excoriation of ear canal
  - atrophic and scaly epidermal lining, ± otorrhea, ± hearing loss
  - wide meatus but no pain with movement of auricle
  - tympanic membrane appears normal

Treatment
- clean ear under magnification with irrigation, suction, dry swabbing, and C&S
- bacterial etiology
  - antipseudomonal otic drops (e.g. ciprofloxacin) or a combination of antibiotic and steroid (e.g. Cipro HC®)
  - do not use aminoglycoside if the tympanic membrane (TM) is perforated because of the risk of ototoxicity
  - introduction of fine gauze wick (pope wick) if external canal edematous
  - ± 3% acetic acid solution to acidify ear canal (low pH is bacteriostatic)
  - systemic antibiotics if either cervical lymphadenopathy or cellulitis is present
- fungal etiology
  - repeated debridement and topical antifungals (gentian violet, Mycostatin® powder, boric acid, Locacorten®, Vioform® drops)
  - ± analgesics
  - chronic otitis externa (pruritus without obvious infection) → corticosteroid alone (e.g. diprosalic acid)

Malignant (Necrotizing) Otitis Externa (Skull Base Osteomyelitis)

Definition
- osteomyelitis of the temporal bone

Epidemiology
- occurs in elderly diabetics and immunocompromised patients

Etiology
- rare complication of otitis externa
- Pseudomonas infection in 99% of cases

Clinical Features
- otalgia and purulent otorrhea that is refractory to medical therapy
- granulation tissue on the floor of the auditory canal

Complications
- cranial nerve palsies (most commonly VII>X>XI)
- systemic infection, death

Management
- imaging: high resolution temporal bone CT scan, gadolinium enhanced MRI, technetium scan
- requires hospital admission, debridement, IV antibiotics, hyperbaric O₂
- may require OR for debridement of necrotic tissue/bone

Gallium and Technetium Scans
Gallium scans are used to show sites of active infection. Gallium is taken up by PMNs and therefore only lights up when active infection is present. It will not show the extent of osteomyelitis. Technetium scans provide information about osteoblastic activity and as such are used to demonstrate sites of osteomyelitis. Technetium scans help with diagnosis whereas gallium scans are useful in follow-up.
Diseases of the Middle Ear

Acute Otitis Media (AOM) and Otitis Media with Effusion (OME)

• see Pediatric Otolaryngology, OT38

Cholesteatoma

Definition
• a cyst composed of keratinizing squamous epithelium occurring in the middle ear, mastoid, and temporal bone
• two types: congenital and acquired

Congenital
• presents as a “small white pearl” behind an intact tympanic membrane (anterior and medial to the malleus) or as a conductive hearing loss
• believed to be due to aberrant migration of external canal ectoderm during development
• not associated with otitis media/Eustachian tube dysfunction

Acquired (more common)
• generally occurs as a consequence of otitis media and chronic Eustachian tube dysfunction
• frequently associated with retraction pockets in the pars flaccida (1° acquired) and marginal perforations (2° acquired) of the tympanic membrane
• the associated chronic inflammatory process causes progressive destruction of surrounding bony structures

Clinical Features
• symptoms:
  ▪ history of otitis media (especially if unilateral), ventilation tubes, ear surgery
  ▪ progressive hearing loss (predominantly conductive although may get sensorineural hearing loss in late stage)
  ▪ otalgia, aural fullness, fever
• signs:
  ▪ retraction pocket in TM, may contain keratin debris
  ▪ TM perforation
  ▪ granulation tissue, polyp visible on otoscopy
  ▪ malodorous, unilateral otorrhea

Complications

<table>

</tr>
<tr>
<td>Temporal bone infection: mastoiditis, petrositis</td>
<td>Intracranial abscess (subdural, epidural, cerebellar)</td>
</tr>
<tr>
<td>Facial paralysis</td>
<td></td>
</tr>
</tbody>
</table>

Investigations
• audiogram and CT scan

Treatment
• there is no conservative therapy for cholesteatoma
• surgical: mastoidectomy ± tympanoplasty ± ossicular reconstruction

Mastoiditis

Definition
• infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two weeks after onset of untreated or inadequately treated acute suppurative otitis media

Etiology
• acute mastoiditis caused by the same organisms as AOM: S. pneumoniae, H. influenzae, M. catarrhalis, S. pyogenes, S. aureus, P. aeruginosa

Complications of AOM are rare due to rapid and effective treatment of AOM with antibiotics.
Clinical Features
- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, hearing loss, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)

Treatment
- IV antibiotics with myringotomy and ventilation tubes – usually all that is required acutely
- cortical mastoidectomy:
  - debridement of infected tissue allowing aeration and drainage
- indications for surgery:
  - failure of medical treatment after 48 h
  - symptoms of intracranial complications
  - aural discharge persisting for 4 wk and resistant to antibiotics

Otosclerosis

Definition
- fusion of stapes footplate to oval window so that it cannot vibrate

Etiology
- autosomal dominant, variable penetrance approximately 40%
- female > male, progresses during pregnancy (hormone responsive)

Clinical Features
- progressive conductive hearing loss first noticed in teens and 20s (may progress to sensorineural hearing loss if cochlea involved)
- ± pulsatile tinnitus
- tympanic membrane normal ± pink blush (Schwartz's sign) associated with the neovascularization of otosclerotic bone
- characteristic dip at 2000 Hz (Carhart's notch) on audiogram (see Figure 16C, OT10)

Treatment
- monitor with serial audiograms if coping with loss
- hearing aid (air conduction, bone conduction, BAHA)
- stapedectomy or stapedotomy (with laser or drill) with prosthesis is definitive treatment

Diseases of the Inner Ear

Congenital Sensorineural Hearing Loss

Hereditary Defects
- non-syndrome associated (70%):
  - often idiopathic, autosomal recessive
  - connexin 26 (GJB2) most common
- syndrome associated (30%):
  - Waardenburg: white forelock, heterochromia iridis (each eye different color), wide nasal bridge and increased distance between medial canthi
  - Pendred: deafness associated with thyroid gland disorders, SLC26A4 gene, enlarged vestibular aqueducts
  - Treacher-Collins: first and second branchial cleft anomalies
  - Alport: hereditary nephritis

Prenatal TORCH Infections
- toxoplasmosis, rubella, CMV, herpes simplex, others (e.g. HIV, syphilis)

Perinatal
- Rh incompatibility
- anoxia
- hyperbilirubinemia
- birth trauma (hemorrhage into inner ear)

Postnatal
- meningitis, mumps, measles
High Risk Factors (for Hearing Loss in Newborns)
- low birth weight/prematurity
- perinatal anoxia (low APGARs)
- kernicterus: bilirubin >25 mg/dL
- craniofacial abnormality
- family history of deafness in childhood
- 1st trimester illness: TORCH infections
- neonatal sepsis
- ototoxic drugs
- perinatal infection, including post-natal meningitis
- consanguinity
- 50-75% of newborns with sensorineural hearing loss have at least one of the above risk factors, and 90% of these have spent time in the NICU
- presence of any risk factor: ABR study performed before leaving NICU and at 3 mo adjusted age
- early rehabilitation improves speech and school performance

Presbycusis

Definition
- sensorineural hearing loss associated with aging (starting in 5th and 6th decades)

Etiology
- hair cell degeneration
- age related degeneration of basilar membrane, possibly genetic etiology
- cochlear neuron damage
- ischemia of inner ear

Clinical Features
- progressive, bilateral hearing loss initially at high frequencies, then middle frequencies
- loss of discrimination of speech especially with background noise present - patients describe people as mumbling
- recruitment phenomenon: inability to tolerate loud sounds
- tinnitus

Treatment
- hearing aid if patient has difficulty functioning, hearing loss >30-35 dB, and good speech discrimination
- ± lip reading, auditory training, auditory aids (doorbell and phone lights)

Sudden Sensorineural Hearing Loss

Clinical Features
- presents as a sudden onset of significant SNHL (usually unilateral) ± tinnitus, aural fullness
- usually idiopathic, rule out other causes:
  - autoimmune causes (e.g. ESR, rheumatoid factor, ANA)
  - MRI to rule out tumour and/or CT to rule out ischemic/hemorrhagic stroke if associated with any other focal neurological signs (e.g. vertigo, ataxia, abnormality of CN V or VII, weakness)

Treatment
- oral corticosteroids within 3 d of onset: prednisone 1 mg/kg/d for 10-14 d

Prognosis
- depends on degree of hearing loss
- 70% resolve within 10 to 14 d
- 20% experience partial resolution
- 10% experience permanent hearing loss

Autoimmune Inner Ear Disease

Etiology
- idiopathic
- may be associated with systemic autoimmune diseases (i.e. rheumatoid arthritis, SLE), vasculitides (i.e. granulomatosis with polyangiitis, polyarteritis nodosa) and allergies

Epidemiology
- most common between ages 20-50
Clinical Features
• rapidly progressive or fluctuating bilateral SNHL
• ± tinnitus, aural fullness, vestibular symptoms (i.e. ataxia, disequilibrium, vertigo)

Investigations
• autoimmune work-up: CBC, ESR, ANA, rheumatoid factor

Treatment
• high-dose corticosteroids: treat early for at least 30 d
• consider cytotoxic medication for steroid non-responders

Drug Ototoxicity

Aminoglycosides
• streptomycin and gentamicin (vestibulotoxic), kanamycin and tobramycin (cochleotoxic)
• toxic to hair cells by any route: oral, IV, and topical (if the TM is perforated)
• destroys sensory hair cells: outer first, inner second (therefore otoacoustic emissions are lost first)
• high frequency hearing loss develops earliest
• ototoxicity occurs days to weeks post-treatment
• must monitor with peak and trough levels when prescribed, especially if patient has neutropenia and/or history of ear or renal problems
• q24h dosing recommended (with amount determined by creatinine clearance)
• aminoglycoside toxicity displays saturable kinetics therefore once daily dosing presents less risk than divided daily doses
• duration of treatment is the most important predictor of ototoxicity
• treatment: immediately stop aminoglycosides

Salicylates
• hearing loss with tinnitus, reversible if discontinued

Antimalarials (Quinines)
• hearing loss with tinnitus
• reversible if discontinued but can lead to permanent loss

Others
• many antineoplastic agents are ototoxic (weigh risks vs. benefits)
• loop diuretics

Noise-Induced Sensorineural Hearing Loss

Pathogenesis
• 85 to 90 dB over months or years or single sound impulses >135 dB can cause cochlear damage
• bilateral SNHL initially and most prominently at 4000 Hz (resonant frequency of the temporal bone), known as “boilermaker's notch” on audiogram, extends to higher and lower frequencies with time (see Figure 16D, OT10)
• speech reception not altered until hearing loss >30 dB at speech frequency, therefore considerable damage may occur before patient complains of hearing loss
• difficulty with speech discrimination, especially in situations with competing noise

Phases of Hearing Loss
• dependent on: intensity of sound and duration of exposure
• temporary threshold shift:
  ▪ when exposed to loud sound, decreased sensitivity or increased threshold for sound
  ▪ may have associated aural fullness and tinnitus
  ▪ with removal of noise, hearing returns to normal
• permanent threshold shift:
  ▪ hearing does not return to previous state

Treatment
• hearing aid
• prevention:
  ▪ ear protectors: muffs, plugs
  ▪ limit exposure to noise with frequent rest periods
  ▪ regular audiologic follow-up
Temporal Bone Fractures

</tbody>
</table>

• characterized as longitudinal or transverse relative to the long axis of the petrous temporal bone
• rarely are temporal bone fractures purely transverse or longitudinal, often it is a mixed picture

Diagnosis
• otoscopy
• do not syringe or manipulate external auditory meatus due to risk of inducing meningitis via TM perforation
• CT head
• audiology, facial nerve tests (for transverse fractures), Schirmer’s test (of lacrimation), stapedial reflexes if CN VII palsy
• if suspecting CSF leak: look for halo sign, send fluid for β-2 transferrin

Treatment
• ABCs
• medical – expectant, prevent otogenic meningitis
• surgical – explore temporal bone, indications:
  • CN VII palsy (immediate and complete)
  • gunshot wound
  • depressed fracture of external auditory meatus
  • early meningitis (mastoidectomy)
  • bleeding intracranially from sinus
  • CSF otorrhea (may resolve spontaneously)

Complications
• acute otitis media ± labyrinthitis ± mastoiditis
• meningitis/epidural abscess/brain abscess
• post-traumatic cholesteatoma

Facial Nerve (CN VII) Paralysis

Etiology
• supranuclear and nuclear (MS, poliomyelitis, cerebral tumours)
• infranuclear (see Table 9)

Treatment
• treat according to etiology plus provide corneal protection with artificial tears, nocturnal lid taping, tarsorrhaphy, gold weighting of upper lid
• facial paralysis that does not resolve with time or with medical treatment will often be referred for possible reanimation techniques to restore function
  • common reanimation techniques include:
    • direct facial nerve anastomosis
    • interpositional grafts
    • anastomosis to other motor nerves
    • muscle transpositions

House-Brackmann Facial Nerve Grading System

Grade I: Normal facial motor function
Grade II: Mild dysfunction
  • Slight weakness
  • Normal symmetry and tone at rest
  • Complete eye closure
Grade III: Moderate dysfunction
  • Obvious weakness
  • Incomplete eye closure
  • No forehead motion
  • Mouth asymmetric motion
Grade IV: Moderately severe dysfunction
  • Obvious weakness
  • Disfiguring asymmetry
  • No forehead motion
Grade V: Severe dysfunction
  • Barely perceptible motion of mouth
  • Asymmetric at rest
Grade VI: Total paralysis
  • No movement

**Allergic Rhinitis (Hay Fever)**

**Definition**
- rhinitis characterized by an IgE-mediated hypersensitivity to foreign allergens
- acute-and-seasonal or chronic-and-perennial
- perennial allergic rhinitis often confused with recurrent colds

**Etiology**
- when allergens contact the respiratory mucosa, specific IgE antibody is produced in susceptible hosts
- concentration of allergen in the ambient air correlates directly with the rhinitis symptoms

**Epidemiology**
- age at onset usually <20 yr
- more common in those with a personal or family history of allergies/atopy

**Clinical Features**
- nasal: obstruction with pruritus, sneezing
- clear rhinorrhea (containing increased eosinophils)
- itching of eyes with tearing
- frontal headache and pressure
- mucosa: swollen, pale, “boggy”
- seasonal (summer, spring, early autumn)
  - pollens from trees
  - lasts several weeks, disappears and recurs following year at same time
- perennial
  - inhaled: house dust, wool, feathers, foods, tobacco, hair, mould
  - ingested: wheat, eggs, milk, nuts
  - occurs intermittently for years with no pattern or may be constantly present

**Complications**
- chronic sinusitis/polyps
- serous otitis media

**Diagnosis**
- history
- direct exam
- allergy testing

**Treatment**
- education: identification and avoidance of allergen
- nasal irrigation with saline
- antihistamines (e.g. diphenhydramine, fexofenadine)
- oral decongestants (e.g. pseudoephedrine, phenylpropanolamine)
- topical decongestant (may lead to rhinitis medicamentosa)
- other topicals: steroids (fluticasone), disodium cromoglycate, antihistamines, ipratropium bromide
- oral steroids if severe
- desensitization by allergen immunotherapy
Vasomotor Rhinitis

- neurovascular disorder of nasal parasympathetic system (vidian nerve) affecting mucosal blood vessels
- nonspecific reflex hypersensitivity of nasal mucosa
- caused by:
  - temperature change
  - alcohol, dust, smoke
  - stress, anxiety, neurosis
  - endocrine: hypothyroidism, pregnancy, menopause
  - parasympathomimetic drugs
- beware of rhinitis medicamentosa: reactive vasodilation due to prolonged use (>5 d) of nasal drops and sprays (Dristan®, Otrivin®)

Clinical Features
- chronic intermittent nasal obstruction, varies from side to side
- rhinorrhea: thin, watery
- mucosa and turbinates: swollen
- nasal allergy must be ruled out

Treatment
- elimination of irritant factors
- parasympathetic blocker (Atrovent® nasal spray)
- steroids (e.g. beclomethasone, fluticasone)
- surgery (often of limited lasting benefit): electrocautery, cryosurgery, laser treatment or removal of inferior or middle turbinates
- vidian neurectomy (rarely done)
- symptomatic relief with exercise (increased sympathetic tone)

Rhinosinusitis

Pathogenesis of Rhinosinusitis
- ostial obstruction or dysfunctional cilia permit stagnant mucous and consequently infection
- all sinuses drain to a common prechamber under the middle meatus called the osteomeatal complex

Definition
- inflammation of the mucosal lining of the sinuses and nasal passages

Classification
- acute: <4 wk
- subacute: 4-8 wk
- chronic: >8-12 wk

Table 12. Etiologies of Rhinosinusitis

</table>
**Acute Bacterial Rhinosinusitis**

**Definition**
- bacterial infection of the paranasal sinuses and nasal passages lasting >7 d
- clinical diagnosis requiring ≥2 major symptoms, at least one of the symptoms is either nasal obstruction or purulent/dischcoloured nasal discharge

- **major symptoms**
  - facial pain/pressure/fullness
  - nasal obstruction
  - purulent/discoloured nasal discharge
  - hyposmia/anosmia

- **minor symptoms**
  - headache
  - halitosis
  - fatigue
  - dental pain
  - cough
  - ear pain/fullness

**Etiology**
- bacteria: *S. pneumoniae* (35%), *H. influenzae* (35%), *M. catarrhalis*, *S. aureus*, anaerobes (dental)
- children are more prone to a bacterial etiology, but viral is still more common
- maxillary sinus most commonly affected
- must rule out fungal causes (mucormycosis) in immunocompromised hosts (especially if painless, black or pale mucosa on examination)

**Clinical Features**
- sudden onset of
  - nasal blockage/congestion and/or purulent nasal discharge/posterior nasal drip
  - ± facial pain or pressure, hyposmia, sore throat
- persistent/worsening symptoms >5 to 7 d or presence of purulence for 3 to 4 d with high fever
- speculum exam: erythematous mucosa, mucopurulent discharge, pus originating from the middle meatus
- predisposing factors: viral URTI, allergy, dental disease, anatomical defects
- differentiate from acute viral rhinosinusitis (course: <10 d, peaks by 3 d)

**Management**
- depends on symptom severity (i.e. intensity/duration of symptoms, impact on quality of life)
- mild-moderate: INCS
  - if no response within 72 h, add antibiotics
- severe: INCS + antibiotics
- antibiotics:
  - 1st line: amoxicillin x 10 d (TMP-SMX or macrolide if penicillin allergy)
  - if no response to 1st line antibiotics within 72 h, switch to 2nd line
  - 2nd line: fluoroquinolones or amoxicillin-clavulanic acid inhibitors
- adjuvant therapy (saline irrigation, analgesics, oral/topical decongestant) may provide symptomatic relief
- CT indicated only if complications are suspected

**Chronic Rhinosinusitis**

**Definition**
- inflammation of the mucosa of paranasal sinuses and nasal passages >8 to 12 wk
- diagnosis requiring ≥2 major symptoms for >8 to 12 wk and ≥1 objective finding of inflammation of the paranasal sinuses (CT/endoscopy)

**Etiology**
- unclear etiology but the following may contribute or predispose:
  - inadequate treatment of acute rhinosinusitis
  - bacterial colonization/biofilms
    - *S. aureus*, *enterobacteriaeae*, *pseudomonas*, *S. pneumoniae*, *H. influenzae*, β-hemolytic streptococci
  - fungal infection (e.g. *Aspergillus*, *Zygomycetes*, *Candida*)
  - anatomic abnormality (e.g. lost ostia patency, deviated septum – predisposing factors)
  - allergy/allergic rhinitis
  - ciliary disorder (e.g. cystic fibrosis, Kartenger’s)
  - chronic inflammatory disorder (e.g. granulomatosis with polyangiitis)
  - untreated dental disease

**Acute Rhinosinusitis Complications**
Consider hospitalization if any of the following are suspected
- Orbital (Chandler’s classification)
  - Periorbital cellulitis
  - Orbital cellulitis
  - Subperiosteal abscess
  - Orbital abscess
  - cavernous sinus thrombosis
- Intracranial
  - Meningitis
  - Abscess
- Bony
  - Subperiosteal frontal bone abscess (“Pott’s Puffy tumour”)
  - Osteomyelitis
- Neurologic
  - Superior orbital fissure syndrome (CN III/IV/VI palsy, immobile globe, dilated pupils, ptosis, V1 hypesthesia)
  - Orbital apex syndrome (as above, plus neuritis, papilledema, decreased visual acuity)

**FESS = Functional Endoscopic Sinus Surgery**
Opening of the entire osteomeatal complex in order to facilitate drainage while sparing the sinus mucosa.

**Allergic fungal rhinosinusitis** is a chronic sinusitis affecting mostly young, immunocompetent, atopic individuals. Treatment options include FESS ± intranasal topical steroids, antifungals, and immunotherapy.
Clinical Features (similar to acute, but less severe)
- chronic nasal obstruction
- purulent anterior/posterior nasal discharge
- facial congestion/fullness
- facial pain/pressure
- hyposmia/anosmia
- halitosis
- chronic cough
- maxillary dental pain

Management
- identify and address contributing or predisposing factors
- obtain CT or perform endoscopy
- if polyps present: INCS, oral steroids ± antibiotics (if signs of infection), refer to Otolaryngologist/Head and Neck Surgeon
- if polyps absent: INCS, antibiotics, saline irrigation, oral steroids (severe cases)
- antibiotics for 3 to 6 wk
  - amoxillin-clavulanic acid inhibitors, fluoroquinolone (moxifloxacin), macrolide (clarithromycin), clindamycin, Flagyl® (metronidazole)
- surgery if medical therapy fails or fungal sinusitis: FESS, balloon sinoplasty

Complications
- same as acute sinusitis, mucocele

Epistaxis

Blood Supply to the Nasal Septum (see Figure 4, OT3)
1. Superior posterior septum:
   - internal carotid → ophthalmic → anterior/posterior ethmoidal
2. Posterior septum:
   - external carotid → internal maxillary → sphenopalatine artery → nasopalatine
3. Lower anterior septum:
   - external carotid → facial artery → superior labial artery → nasal branch
   - external carotid → internal maxillary → descending palatine → greater palatine
- these arteries all Anastomose to form Kiesselbach's plexus, located at Little's area (anterior-inferior portion of the cartilaginous septum)
- bleeding from above middle turbinate is internal carotid, and from below is external carotid

Table 13. Etiology of Epistaxis

</tbody>
</table>

Special Cases
- Adolescent male with unilateral recurrent epistaxis – consider juvenile nasopharyngeal angiofibroma (JNA). This is the most common benign tumour of the nasopharynx
- Thrombocytopenic patients – use resorbable packs to avoid risk of re-bleeding caused by pulling out the removable pack

Investigations
- CBC, PT/PTT (if indicated)
- x-ray, CT as needed

Treatment
- locate bleeding and achieve hemostasis

1. ABCs
- patient leans forward to minimize swallowing blood and avoid airway obstruction
- apply constant firm pressure for 20 min on cartilaginous part of nose (not bony pyramid)
- if significant bleeding, assess vitals for signs of hemorrhagic shock ± IV NS, cross match blood
2. Determine Site of Bleeding
- anterior/posterior hemorrhage defined by location in relationship to bony septum
- visualize nasal cavity with speculum
- use cotton pledget with topical lidocaine ± topical decongestant (i.e. Otrivin®) to help identify area of bleeding (often anterior septum)
- if suspicion of bleeding disorder, coagulation workup (platelet number and platelet function assay)

3. Control the Bleeding
- first line topical vasoconstrictors (Otrivin®)
- if first line fails and bleeding adequately visualized, cauterize with silver nitrate
- **do not cauterize both sides of the septum** at one time due to risk of septal perforation from loss of septal blood supply

   A. Anterior hemorrhage treatment
   - if fail to achieve hemostasis with cauterization:
     - place anterior pack* with half inch Vaseline®-soaked ribbon gauze strips layered from nasal floor toward nasal roof extending to posterior choanae or lubricated absorbable packing (i.e. Gelfoam wrapped in Surgicel®) for 2 to 3 d
     - can also attempt packing with Merocel® or nasal tampons of different shapes
     - can also apply Floseal® (hemostatic matrix consisting of topical human thrombin and cross-linked gelatin) if other methods fail

   B. Posterior hemorrhage treatment
   - if unable to visualize bleeding source, then usually posterior source:
     - place posterior pack* using a Foley catheter, gauze pack, or Epistat® balloon
     - subsequently, layer anterior packing bilaterally
     - admit to hospital with packs in for 3 to 5 d
     - watch for complications: hypoxemia (naso-pulmonic reflex), toxic shock syndrome (Rx: remove packs immediately), pharyngeal fibrosis/stenosis, alar/septal necrosis, aspiration

   C. If anterior/posterior packs fail to control epistaxis
   - ligation or embolization of culprit arterial supply by interventional radiology
   - ± septoplasty

* antibiotics for any posterior pack or any pack left for >48 h because of risk of toxic shock syndrome

4. Prevention
- prevent drying of nasal mucosa with humidifiers, saline spray, or topical ointments
- avoidance of irritants
- medical management of hypertension and coagulopathies

---

**Hoarseness**

**Definitions**
- hoarseness: change in voice quality, ranging from voice harshness to voice weakness. Reflects abnormalities anywhere along the vocal tract from oral cavity to lungs
- dysphonia: a general alteration in voice quality
- aphonia: no sound emanates from vocal folds

**Acute Laryngitis**

**Definition**
- <2 wk inflammatory changes in laryngeal mucosa

**Etiology**
- viral: influenza, adenovirus
- bacterial: Group A Streptococcus
- mechanical acute voice strain ✄ submucosal hemorrhage ✄ vocal cord edema ✄ hoarseness
- environmental: toxic fume inhalation

**Clinical Features**
- URTI symptoms, hoarseness, aphony, cough attacks, ± dyspnea
- true vocal cords erythematous/edematous with vascular injection and normal mobility

**Treatment**
- usually self-limited, resolves within ~1 wk
- voice rest
- humidification
- hydration
- avoid irritants (e.g. smoking)
- treat with antibiotics if there is evidence of coexistent bacterial pharyngitis

If hoarseness present for > 2 wk in a smoker, laryngoscopy must be done to rule out malignancy.

**Vocal Cord Paralysis**

Unilateral: affected cord lies in the parmedian position, inadequate glottic closure during phonation → weak, breathy voice. Usually medializes with time whereby phonation and aspiration improve. Treatment options include voice therapy, injection laryngoplasty (Radiesse), medialization using silastic block.

Bilateral: cords rest in midline therefore voice remains good but respiratory function is compromised and may present as stridor. If no respiratory issues, may monitor closely and wait for improvement. If respiratory issues, intubate and will likely require a tracheotomy.
Chronic Laryngitis

Definition
• >2 wk inflammatory changes in laryngeal mucosa

Etiology
• repeated attacks of acute laryngitis
• chronic irritants (dust, smoke, chemical fumes)
• chronic voice strain
• chronic rhinosinusitis with postnasal drip
• chronic alcohol use
• esophageal disorders: GERD, Zenker's diverticulum, hiatus hernia
• systemic: allergy, hypothyroidism, Addison's disease

Clinical Features
• chronic dysphonia: rule out malignancy
• cough, globus sensation, frequent throat clearing 2º to GERD
• laryngoscopy: cords erythematous, thickened with ulceration/granuloma formation, and normal mobility

Treatment
• remove offending irritants
• treat related disorders (e.g. antisecretory therapy for GERD)
• speech therapy with voice rest
• ± antibiotics ± steroids to decrease inflammation
• laryngoscopy to rule out malignancy

Vocal Cord Polyps

Definition
• structural manifestation of vocal cord irritation
• acutely, polyp forms 2º to capillary damage in the subepithelial space during extreme voice exertion

Etiology
• most common benign tumour of vocal cords
• voice strain (muscle tension dysphonia)
• laryngeal irritants (GERD, allergies, tobacco)

Epidemiology
• 30 to 50 yr of age
• M>F

Clinical Features
• hoarseness, aphony, cough attacks ± dyspnea
• pedicled or sessile polyp on free edge of vocal cord
• typically polyp asymmetrical, soft, and smooth
• more common on the anterior 1/3 of the vocal cord
• intermittent respiratory distress with large polyps

Treatment
• avoid irritants
• endoscopic laryngeal microsurgical removal if persistent or if high risk of malignancy

Vocal Cord Nodules

Definition
• vocal cord callus
• aka “screamer's or singer's nodules”

Etiology
• early nodules occur 2º to submucosal hemorrhage
• mature nodules result from hyalinization which occurs with long term voice abuse
• chronic voice strain
• frequent URTI, smoke, alcohol
Epidemiology
- frequently in singers, children, bartenders, and school teachers
- F>M

Clinical Features
- hoarseness worst at end of day
- on laryngoscopy:
  - often bilateral
  - at the junction of the anterior 1/3 and posterior 2/3 of the vocal cords – point of maximal cord vibration
- chronic nodules may become fibrotic, hard, and white

Treatment
- voice rest
- hydration
- speech therapy
- avoid irritants
- surgery rarely indicated for refractory nodules

Benign Laryngeal Papillomas

Etiology
- HPV types 6, 11
- possible hormonal influence, possibly acquired during delivery

Epidemiology
- biphasic distribution: 1) birth to puberty (most common laryngeal tumour) and 2) adulthood

Clinical Features
- hoarseness and airway obstruction
- can seed into tracheobronchial tree
- highly resistant to complete removal
- some juvenile papillomas resolve spontaneously at puberty
- may undergo malignant transformation
- laryngoscopy shows wart-like lesions in supraglottic larynx and trachea

Treatment
- microdebridement or CO₂ laser
- adjuvants under investigation: interferon, cidofovir, acyclovir
- HPV vaccine may prevent/decrease the incidence but more research is needed

Laryngeal Carcinoma

- see Neoplasms of the Head and Neck, OT34

Salivary Glands

Sialadenitis

Definition
- inflammation of salivary glands

Etiology
- viral most common (mumps)
- bacterial causes: S. aureus, S. pneumoniae, H. influenzae
- obstructive vs. non-obstructive
- obstructive infection involves salivary stasis and bacterial retrograde flow

Predisposing Factors
- HIV
- anorexia/bulimia
- Sjögren's syndrome
- Cushing’s, hypothyroidism, DM
- hepatic/renal failure
- meds that increase stasis: diuretics, TCAs, β-blockers, anticholinergics, antibiotics
- sialolithiasis (can cause chronic sialadenitis)
Clinical Features
- acute onset of pain and edema of parotid or submandibular gland that may lead to marked swelling
- ± fever
- ± leukocytosis
- ± suppurative drainage from punctum of the gland

Investigations
- U/S imaging to differentiate obstructive vs. non-obstructive sialadenitis

Treatment
- bacterial: treat with cloxacillin ± abscess drainage, sialogogues
- viral: no treatment

Sialolithiasis

Definition
- ductal stone (mainly hydroxyapatite) in adults, sand/sludge in children, leading to chronic sialadenitis
- 80% in submandibular gland, <20% in parotid gland, ~1% in sublingual gland

Risk Factors
- any condition causing duct stenosis or a change in salivary secretions (e.g. dehydration, diabetes, EtOH, hypercalcemia, psychiatric medication)

Clinical Features
- pain and tenderness over involved gland
- intermittent swelling related to meals
- digital palpation reveals presence of calculus

Investigations
- ultrasound ± sialogram

Treatment
- may resolve spontaneously
- encourage salivation to clear calculus
- massage, analgesia, antibiotics, sialogogues (e.g. lemon wedges, sour lemon candies), warm compresses
- remove calculi endoscopically, by dilating duct or orifice, or by excision through floor of the mouth
- if calculus is within the gland parenchyma, the whole gland must be excised

Salivary Gland Neoplasms

Etiology
- anatomic distribution
  - parotid gland: 70-85%
  - submandibular gland: 8-15%
  - sublingual gland: 1%
  - minor salivary glands, most concentrated in hard palate: 5-8%
- malignant (see Table 15, OT35 and Table 16, OT36)
- benign
  - benign mixed (pleomorphic adenoma): 80%
  - Warthin's tumour (5 to 10% bilateral, M>F): 10%
  - cysts, lymph nodes and adenomas: 10%
  - oncocytoma: <1%

Epidemiology
- 3 to 6% of all head and neck neoplasms in adults
- mean age at presentation: 55 to 65
- M=F
Parotid Gland Neoplasms

Clinical Features
- 80% benign (pleomorphic adenoma – most common), 20% malignant (mucoepidermoid – most common)
- painless slow-growing mass
- if bilateral, suggests benign process (Warthin’s tumour, Sjögren’s, bulimia, mumps) or possible lymphoma

Investigations
- FNA biopsy
- CT or MRI to determine extent of tumour

Treatment
- treatment of choice is surgery for all salivary gland neoplasms – benign and malignant
- pleomorphic adenomas are excised due to risk of malignant transformation (5% risk over prolonged period of time)
  - superficial tumour
    - superficial parotidectomy above plane of CN VII ± radiation
    - incisional biopsy contraindicated
  - deep lesion
    - near-total parotidectomy sparing as much of CN VII as possible
    - if CN VII involved then it is removed and cable grafted
- complications of parotid surgery
  - hematoma, infection, salivary fistula, temporary facial paresis, Frey’s syndrome (gustatory sweating)

Prognosis
- benign: excellent, <5% of pleomorphic adenomas may recur
- malignant: dependent on stage and type of malignancy (see OT36)

Neck Masses

Approach to a Neck Mass

- ensure that the neck mass is not a normal neck structure (hyoid, transverse process of C1 vertebra, prominent carotid bulb)
- any neck mass persisting for more than 2 wk should be investigated for possible neoplastic causes

Table 14. Acquired Causes of Neck Lumps According to Age

<table>
<thead>
<tr>
<th>Age (yr)</th>
<th>Possible Causes of Neck Lump</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-40</td>
<td>1. Inflammatory 2. Congenital 3. Neoplastic</td>
</tr>
<tr>
<td>&gt;40</td>
<td>1. Neoplastic 2. Inflammatory 3. Congenital</td>
</tr>
</tbody>
</table>

Differential Diagnosis
- congenital
  - lateral (branchial cleft cyst, lymphatic/venous/venolymphatic malformation)
  - midline (thyroglossal duct cyst, dermoid cyst, laryngocele)
- infectious/inflammatory
  - reactive lymphadenopathy (2nd to tonsillitis, pharyngitis)
  - infectious mononucleosis
  - Kawasaki, Kikuchi, Kimura
  - HIV
  - salivary gland calculi, sialadenitis
  - thyroiditis
- granulomatous disease
  - mycobacterial infections
  - sarcoidosis
- neoplastic
  - lymphoma
  - salivary gland tumours
  - thyroid tumours
  - metastatic malignancy (“unknown primary”)
## Evaluation

### Investigations
- history and physical (including nasopharynx and larynx)
- all other investigations and imaging are dependent upon clinical suspicion following history and physical
- laboratory investigations
  - WBC: infection vs. lymphoma
  - Mantoux TB test
  - thyroid function tests and scan
- imaging
  - neck U/S
  - CT scan
  - angiography: vascularity and blood supply to mass
  - radiologic exam of stomach, bowel and sinuses
- biopsy: for histologic examination
  - FNA: least invasive
  - needle biopsy
  - open biopsy: for lymphoma
- identification of possible primary tumour (rule out a metastatic lymph node from an “unknown primary”)
  - panendoscopy: nasopharyngoscopy, laryngoscopy, esophagoscopy, bronchoscopy with washings, and biopsy of suspicious lesions
  - biopsy of normal tissue of nasopharynx, tonsils, base of tongue, and hypopharynx
  - primary identified 95% of time → stage and treat
  - primary occult 5% of time: excisional biopsy of node for histologic diagnosis → manage with radiotherapy and/or neck dissection (squamous cell carcinoma)

## Congenital Neck Masses

### Branchial Cleft Cysts/Fistula

#### Embryology
- at the 6th week of development, the 2nd branchial arch grows over the 3rd and 4th arches and fuses with the neighbouring caudal pre-cardial swelling forming the cervical sinus
- 3 types of malformations:
  1. branchial fistula: persistent communication between skin and GI tract
  2. branchial sinus: blind-ended tract opening to skin
  3. branchial cyst: persistent cervical sinus with no external opening

#### Clinical Features
- 2nd branchial cleft malformations most common
  - sinuses and fistulae present in infancy as a small opening anterior to the sternocleidomastoid muscle
  - cysts present as a smooth, painless, slowly enlarging lateral neck mass, often following an URTI
- 1st branchial cleft malformations present as sinus/fistula or cyst in preauricular area or over angle of mandible
- 3rd branchial cleft malformations present as recurrent thyroiditis or thyroid abscess and have a tract leading usually to the left pyriform sinus
- there is controversy whether or not 4th branchial cleft anomalies exist, as they may be remnants of the thyrothymic axis

#### Treatment
- surgical removal of cyst or fistula tract
- if infected: allow infection to settle before removal
Thyroglossal Duct Cysts

Embryology
- thyroid originates as ventral midline diverticulum at base of tongue caudal to junction of 3rd and 4th branchial arches (foramen cecum) and migrates down to inferior aspect of neck
- thyroglossal duct cysts are vestigial remnants of tract

Clinical Features
- usually presents in childhood or 2nd to 4th decades as a midline cyst that enlarges with URTI and elevates with swallowing and tongue protrusion

Treatment
- pre-operative antibiotics to reduce inflammation
- small potential for neoplastic transformation so complete excision of cyst and tissue around tract up to foramen cecum at base of tongue with removal of central portion of hyoid bone (Sistrunk procedure) recommended
**Lymphatic Malformation**

**Definition**
- lymphatic malformation arising from vestigial lymph channels of neck

**Clinical Features**
- usually present by age 2
- can be macrocystic (composed of large thin-walled cysts, usually below level of mylohyoid muscle) or microcystic (composed of minute cysts, usually above level of mylohyoid muscle)
- usually painless, soft, compressible
- infection causes a sudden increase in size

**Treatment**
- can regress spontaneously after bacterial infection, therefore do not plan surgical intervention until several months after infection
- macrocystic lesions can be treated by sclerotherapy or surgical excision
- microcystic lesions are difficult to treat, but can be debulked

---

**Neoplasms of the Head and Neck**

**Pre-Malignant Disease**
- leukoplakia
  - hyperkeratosis
  - risk of malignant transformation 5 to 20%
- erythroplakia
  - red superficial patches adjacent to normal mucosa
  - commonly associated with epithelial dysplasia
  - associated with carcinoma in situ or invasive tumour in 40% of cases
- dysplasia
  - histopathologic presence of mitoses and prominent nucleoli
  - involvement of entire mucosal thickness = carcinoma in situ
  - associated progression to invasive cancer in 15 to 30% of cases

**Investigations**
- initial metastatic screen includes chest x-ray
- scans of liver, brain, and bone only if clinically indicated
- CT scan is superior to MRI for the detection of pathologic nodal disease and bone cortex invasion
- MRI is superior to discriminate tumour from mucus and to detect bone marrow invasion
- ± PET scans

**Treatment**
- treatment depends on:
  - histologic grade of tumour
  - stage
  - physical and psychological health of patient
  - facilities available
  - expertise and experience of the medical and surgical oncology team
- in general:
  - 1st surgery for malignant oral cavity tumours with radiotherapy reserved for salvage or poor prognostic indicators
  - 1st radiotherapy for nasopharynx, oropharynx, hypopharynx, larynx malignancies with surgery reserved for salvage
  - palliative chemotherapy for metastatic or incurable disease
  - concomitant chemotherapy increases survival in advanced disease
  - chemotherapy has a role as induction therapy prior to surgery and radiation
  - panendoscopy to detect primary disease when lymph node metastasis is identified
  - anti-EGFR treatment (ceftumab, panitumumab) has a role as concurrent therapy with radiation (for advanced local and regional disease)

**Prognosis**
- synchronous tumours occur in 9 to 15% of patients
- late development of 2nd primary most common cause of post-treatment failure after 36 mo
### Table 15. Quick Look-Up Summary of Head and Neck Malignancies – Etiology and Epidemiology

</table>

| **Nose and Paranasal Sinus** | | |
| 75 to 80% SCC | Mean age: 50 to 70 | Wood/shoe/textile industry |
| Adenocarcinoma (2nd most common) and mucoepidermoid | Rare tumours | Hardwood dust (nasal/ethmoid sinus) |
| 99% in maxillary/ethmoid sinus | ↓ incidence in last 5 to 10 yr | Nickel, chromium (maxillary sinus) |
| 10% arise from minor salivary glands | | Air pollution |
| | | Chronic rhinosinusitis |

| **Carcinoma of the Pharynx – Subtypes (Nasopharynx, Oropharynx, Hypopharynx and Larynx)** | | |
| Nasopharynx | | |
| 90% SCC | Mean age: 50 to 59 | Epstein-Barr virus (EBV) |
| ~10% lymphoma | M:F = 2:4:1 | Salted fish |
| | Incidence 0.8 per 100,000 | Nickel exposure |
| | 100x increased incidence in Southern Chinese | Poor oral hygiene |
| | | Genetic – Southern Chinese |

| Oropharynx | Mean age: 50 to 70 | Smoking/EtOH |
| 95% SCC – poorly differentiated | M:F = 4:1 | HPV Infection |
| | | |

| Hypopharynx | | |
| 95% SCC | Mean age: 50 to 70 | Smoking/EtOH |
| 3 sites: | M:F | HPV infection strongly associated with the risk of laryngeal squamous cell cancers (Li et al., 2013) |
| 1. pyriform sinus (60%) | | |
| 2. post-cricoid (30%) | | |
| 3. post pharyngeal wall (10%) | | |

| Larynx | Mean age: 45 to 75 | Smoking/EtOH |
| SCC most common | M:F = 10:1 | HPV 16 infection strongly associated with the risk of laryngeal squamous cell cancers (Li et al., 2013) |
| 3 sites: | | |
| 1. supraglottic (30 to 35%) | | |
| 2. glottic (60 to 65%) | | |
| 3. subglottic (1%) | | |

| Salivary Gland | Mean age: 55 to 65 | |
| 40% mucoepidermoid | M:F | |
| 30% adenoid cystic | 3 to 6% of all H&N cancer | |
| 5% acinic cell | Rate of malignancy: | |
| 5% malignant mixed | Perotid 15 to 25% | |
| 5% lymphoma | Submandibular 37 to 43% | |
| | Minor salivary >80% | |

| Thyroid (90% benign – 10% malignant) | | |
| >80% papillary | Children | Radiation exposure |
| 5-15% follicular | Adults <30 or >60 | Family history – papillary CA or multiple endocrine neoplasia – MEN II |
| 5% medullary | Nodules more common in females | Older age |
| <5% anaplastic | Malignancy more common in males | Male |
| 1 to 5% Hurthle cell | | Papillary – Gardner’s, Cowden’s, familial adenomatous polyposis (FAP) |
| 1 to 2% metastatic | | |

| Parathyroid | Mean age: 44 to 55 yr | |
| Rare tumour | | |

**Risk Factors for Head and Neck Cancer include:**
- Smoking
- EtOH (this is synergistic with smoking)
- Radiation
- Occupational/Environmental exposures
- Oral HPV infection (independent of smoking and EtOH exposure)

* B symptoms = fever, night sweats, weight loss >10% in 6 mo  ** CHOP = cyclophosphamide, adriamycin, vincristine, prednisone

### Approach to Thyroid Nodule

- all patients with thyroid nodules require evaluation of serum TSH and ultrasound
- any nodule >5 mm with suspicious sonographic features (particularly microcalcifications) should undergo FNA
- any nodule >1 cm should undergo FNA
- when performing repeat FNA on initially non-diagnostic nodules, U/S-guided FNA should be employed
- nuclear scanning has minimal value in the investigation of the thyroid nodule

* U/S findings: cystic: risk of malignancy <1%, solid: risk of malignancy approx. 10%, solid with cystic components: risk of malignancy same as if solid
Acute Otitis Media (AOM)

Definition
- acute inflammation of middle ear

Epidemiology
- 60 to 70% of children have at least 1 episode of AOM before 3 yr of age
- 18 mo to 6 yr most common age group
- peak incidence January to April
- one third of children have had ≥3 episodes by age 3

Etiology
- *S. pneumoniae*: 35% of cases (incidence decreasing due to pneumococcus vaccine)
- *H. influenzae*: 25% of cases
- *M. catarrhalis*: 10% of cases
- *S. aureus* and *S. pyogenes* (all β-lactamase producing)
- anaerobes (newborns)
- Gram-negative enterics (infants)
- viral

Predisposing Factors
- Eustachian tube dysfunction/obstruction:
  - swelling of tubal mucosa:
    - upper respiratory tract infection (URTI)
    - allergic rhinitis
    - chronic rhinosinusitis
  - obstruction/infiltration of Eustachian tube ostium:
    - tumour: nasopharyngeal carcinoma (adults)
    - adenoid hypertrophy (not due to obstruction but by maintaining a source of infection)
    - barotrauma (sudden changes in air pressure)
  - inadequate tensor palatini function: cleft palate (even after repair)
  - abnormal Eustachian tube:
    - Down syndrome (horizontal position of Eustachian tube), Crouzon syndrome, and Apert syndrome
- disruption of action of:
  - cilia of Eustachian tube: Kartagener’s syndrome
  - mucus secreting cells
  - capillary network that provides humoral factors, PMNs, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, diabetes mellitus, hypogammaglobulinemia, cystic fibrosis

Risk Factors
- bottle feeding, pacifier use
- second-hand smoke
- crowded living conditions (day care/group child care facilities) or sick contacts
- male
- family history

Pathogenesis
- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features
- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers
  - ear-tugging (this alone is not a good indicator of pathology)
  - hearing loss, balance disturbances (rare)
  - irritable, poor sleeping
  - vomiting and diarrhea
  - anorexia
- otoscopy of TM
  - hyperemia
  - bulging, pus may be seen behind TM
  - loss of landmarks: handle and long process of malleus not visible

Clinical Assessment of AOM in Pediatrics
*JAMA* 2010;304:2161-2169
In assessment of AOM in pediatrics, ear pain is the most useful symptom with a likelihood ratio (LR) between 3.0 and 7.3. Useful otoscopic signs include erythematous (LR 8.4, 95% CI 7-11), cloudy (LR 34, 95% CI 28-42), bulging (LR 51, 95% CI 36-73), and immobile tympanic membrane on pneumatic otoscopy (LR 31, 95% CI 26-37).
Diagnosis and Management

- American Academy of Pediatrics (AAP) Guidelines 2013 suggest the following action statements (adapted):
  - Diagnose AOM if:
    1. Moderate to severe bulging of TM or new onset of otorrhea not due to otitis externa
    2. Mild bulging of tympanic membrane and recent (<48 h) ear pain or intense erythema of TM
    3. Do not diagnose AOM if no middle ear effusion (based on pneumatic otoscopy or tympanometry)

Management of AOM

1. Assess for pain. If pain present, treat the pain
2. For severe unilateral or bilateral AOM (moderate or severe otalgia, or otalgia for 48 h, or temperature ≥39°C), prescribe antibiotics if 6 mo or older
3. For nonsevere bilateral AOM (mild otalgia, otalgia <48 h, temperature <39°C), prescribe antibiotics if 6 to 23 mo
4. For nonsevere unilateral AOM, prescribe antibiotics or observe with close follow up based on joint decision making with parents if 6 to 23 mo
5. For nonsevere unilateral or bilateral AOM, prescribe antibiotics or observe with close follow up based on joint decision making with parents if 24 mo or older
6. Antibiotic treatment when given should consist of:
   - amoxicillin if child has not received amoxicillin in past 30 d, child does not have purulent conjunctivitis, or child is not allergic to penicillin
   - add β-lactamase coverage if received amoxicillin in past 30 d, has purulent conjunctivitis, or has history of recurrent AOM not responsive to amoxicillin
   - reassess if symptoms worsen or fail to respond to treatment within 48 to 72 h
   - do NOT prescribe prophylactic antibiotics to reduce frequency of AOM
7. Tympanostomy tubes can be offered for recurrent AOM (3 episodes in 6 mo, 4 episodes in 1 yr) with 1 episode in preceding 6 mo
8. Recommend pneumococcal vaccine and annual influenza vaccine to all children
9. Encourage exclusive breastfeeding for at least 6 mo
10. Avoid tobacco smoke

- antibiotic treatment hastens resolution: 10 d course
  - 1st line:
    - amoxicillin 80-90 mg/kg/d divided into two doses: safe, effective, and inexpensive
    - if penicillin allergic: macrolide (clarithromycin, azithromycin – high resistance), trimethoprim-sulfamethoxazole (Bactrim®)
  - 2nd line:
    - amoxicillin-clavulanic acid (Clavulin®)
    - cefalosporins: cefuroxime axetil (Ceftin®), ceftriaxone (Rocephin®), cefaclor (Ceclor®), cefixime (Suprax®)
  - AOM deemed unresponsive if clinical signs/symptoms and otoscopic findings persist beyond 48 h of antibiotic treatment
  - symptomatic therapy:
    - antipyretics/analgesics (e.g. acetaminophen)
    - decongestants: may relieve nasal congestion but does not treat AOM

- prevention:
  - parent education about risk factors
  - antibiotic prophylaxis: amoxicillin or macrolide shown effective at half therapeutic dose
  - pneumococcal and influenza vaccine
  - surgery:
    - choice of surgical therapy for recurrent AOM depends on whether local factors (Eustachian tube dysfunction) are responsible (use ventilation tubes), or regional disease factors (tonsillitis, adenoid hypertrophy, sinustitis) are responsible

Complications of AOM

- otortic:
  - TM perforation
  - chronic suppurative OM
  - ossicular necrosis
  - cholesteatoma
  - persistent effusion (often leading to hearing loss)

- CNS:
  - meningitis
  - brain abscess
  - facial nerve paralysis

- other:
  - mastoiditis
  - labyrinthitis
  - sigmoid sinus thrombophlebitis

Complications of Tympanostomy Tubes

- Early:
  - Exudation
  - Blockage
- Persistent otitis
- Late:
  - Myringosclerosis
  - Persistent TM perforation
  - Cholesteatoma
Otitis Media with Effusion (OME)

Definition
• presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology
• most common cause of pediatric hearing loss
• not exclusively a pediatric disease
• follows AOM frequently in children
• middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and 3+ mo in 10%

Risk Factors
• same as AOM

Clinical Features
• hearing loss ± tinnitus
  ▪ confirm with audiogram and tympanogram (flat) (see Figure 16B, OT10 and Figure 17B, OT11)
• fullness – blocked ear
• ± pain, low grade fever
• otoscopy of tympanic membrane:
  ▪ discolouration – amber or dull grey with “glue” ear
  ▪ meniscus fluid level behind TM
  ▪ air bubbles
  ▪ retraction pockets/TM atelectasis
  ▪ most reliable finding with pneumatoscopy is immobility

Treatment
• expectant: 90% resolve by 3 mo
• document hearing loss with audiogram
• no statistical proof that antihistamines, decongestants, antibiotics clear disease faster
• surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
• ventilation tubes to equalize pressure and drain ear

Complications of Otitis Media with Effusion (OME)
• hearing loss, speech delay, learning problems in young children
• chronic mastoiditis
• ossicular erosion
• cholesteatoma especially when retraction pockets involve pars flaccida or postero-superior TM
• retraction of tympanic membrane, atelectasis, ossicular fixation

Adenoid Hypertrophy

• size peaks at age 5 and resolves by age 12
• increase in size with repeated URTI and allergies

Clinical Features
• nasal obstruction:
  ▪ adenoid facies (open mouth, high arched palate, narrow midface, malocclusion)
  ▪ history of hypernasal voice and snoring
  ▪ long term mouth breather; minimal air escape through nose
• choanal obstruction:
  ▪ chronic rhinosinusitis/rhinitis
  ▪ obstructive sleep apnea
• chronic inflammation:
  ▪ nasal discharge, post-nasal drip, and cough
  ▪ cervical lymphadenopathy

Diagnosis
• enlarged adenoids on nasopharyngeal exam (usually with flexible nasopharyngoscope)
• enlarged adenoid shadow on lateral soft tissue x-ray

Complications
• Eustachian tube obstruction leading to serous otitis media
• interference with nasal breathing, necessitating mouth-breathing
• malocclusion
• sleep apnea/respiratory disturbance
• orofacial developmental abnormalities
Adenoidectomy

Indications for Adenoidectomy
- chronic upper airway obstruction with sleep disturbance/apnea ± cor pulmonale
- chronic nasopharyngitis resistant to medical treatment
- chronic serous otitis media and chronic suppurative otitis media (with 2nd set of tubes)
- recurrent acute otitis media resistant to antibiotics
- suspicion of nasopharyngeal malignancy
- persistent rhinorrhea

Contraindications
- uncontrollable coagulopathy
- recent pharyngeal infection
- short or abnormal palate (cleft or false palate, zona pellucida)

Complications
- bleeding, infection
- velopharyngeal insufficiency (hypernasal voice or nasal regurgitation)
- scarring of Eustachian tube orifice

Sleep-Disordered Breathing in Children

Definition
- spectrum of sleep-related breathing abnormalities ranging from snoring to OSA

Epidemiology
- peak incidence between 2 and 8 yr when tonsils and adenoids are the largest relative to the pharyngeal airway

Etiology
- due to a combination of anatomic and neuromuscular factors:
  - adenotonsillar hypertrophy
  - craniofacial abnormalities
  - neuromuscular hypotonia (i.e. cerebral palsy, Down syndrome)
  - obesity

Clinical Features
- heavy snoring, mouth breathing, pauses or apnea, enuresis, excessive daytime sleepiness, behavioural/learning problems, diagnosis of ADHD, morning headache, failure to thrive

Investigations
- flexible nasopharyngoscopy for assessment of nasopharynx and adenoids
- polysomnography (obstructive apnea-hypopnea index >1/h considered abnormal)

Treatment
- surgical: bilateral tonsillectomy and adenoidectomy
- nonsurgical: CPAP, BiPAP, sleep hygiene

Acute Tonsillitis

Etiology
- Group A β-hemolytic streptococci (most common) and Group C or G streptococci
- S. pneumoniae, S. aureus, H. influenzae, M. catarrhalis
- EBV

Clinical Features
- symptoms:
  - sore throat
  - dysphagia, odynophagia, trismus
  - malaise, fever
  - otalgia (referred)
- signs:
  - tender cervical lymphadenopathy, especially submandibular, jugulodigastric
  - tonsils enlarged, inflammation ± exudates/white follicles
  - strawberry tongue, scarlatiniform rash (scarlet fever)
  - palatal petechiae (infectious mononucleosis)

Trismus: motor disturbance of the trigeminal nerve, leading to spasm of the muscles of mastication, with difficulty in opening the mouth (lockjaw).

DDx Sore Throat
- Streptococcal pharyngitis
- Viral pharyngitis
- Infectious mononucleosis
- Tonsillitis
- Peritonsillar abscess
- Foreign body/trauma
- Leukemia
- Hodgkin’s disease
**Investigations**
- CBC
- swab for C&S
- latex agglutination tests
- Monospot® – less reliable in children <2 yr old

**Treatment**
- soft diet, ample fluid intake
- gargle with warm saline solution
- analgesics and antipyretics
- antibiotics:
  - only after appropriate swab for C&S
  - 1st line penicillin or amoxicillin (erythromycin if penicillin allergy) x 10 d
  - rheumatic fever risk emerges approximately 9 d after the onset of symptoms:
    - antibiotics are utilized mainly to avoid this serious sequela and to provide earlier symptomatic relief
    - no evidence for the role of antibiotics in the avoidance of post-streptococcal glomerulonephritis

---

**Peritonsillar Abscess (Quinsy)**

**Definition**
- cellulitis of space behind tonsillar capsule extending onto soft palate leading to abscess

**Etiology**
- bacterial: Group A strep (GAS) (50% of cases), *S. pyogenes, S. aureus, H. influenzae,* and anaerobes

**Epidemiology**
- can develop from acute tonsillitis with infection spreading into plane of tonsillar bed
- unilateral
- most common in 15 to 30 yr old age group

**Clinical Features**
- fever and dehydration
- sore throat, dysphagia, and odynophagia
- extensive peritonsillar swelling but tonsil may appear normal
- edema of soft palate
- uvular deviation
- involvement of motor branch of CN V (can lead to trismus)
- dysphonia (edema → failure to elevate palate) 2º to CN X involvement
- unilateral referred otalgia
- cervical lymphadenitis

**Complications**
- aspiration pneumonia 2º to spontaneous rupture of abscess
- airway obstruction
- lateral dissection into parapharyngeal and/or carotid space
- bacteremia
- retropharyngeal abscess

**Treatment**
- secure airway
- surgical drainage (incision or needle aspiration) with C&S
- warm saline irrigation
- IV penicillin G x 10 d if cultures positive for GAS
- add PO/IV metronidazole or clindamycin x 10 d if culture positive for *Bacteroides*
- consider tonsillectomy after second episode

**Other Parapharyngeal Space Infection**
- pharyngitis
- parotitis (see *Salivary Glands, OT29*)
- otitis
- mastoiditis (Bezold's abscess)
- odontogenic infection
Tonsillectomy

Absolute Indications
- most common indication: sleep-disordered breathing
- 2nd most common indication: recurrent throat infections
- tonsillar hypertrophy causing upper airway obstruction, obstructive sleep apnea, severe dysphagia, or cardiopulmonary complications such as cor pulmonale
- suspicion of malignancy (e.g. lymphoma, squamous cell carcinoma)
- orofacial/dental deformity
- hemorrhagic tonsillitis

Relative Indications (to reduce disease burden)
- recurrent throat infection with a frequency of at least 7 episodes in the past year, at least 5 episodes per year for 2 yr, or at least 3 episodes per year for 3 yr, with documentation in the medical record for each episode of sore throat and 1 or more of the following: temperature >38.3°C, cervical adenopathy, tonsillar exudate, or positive test for Group A β-hemolytic streptococcus (Paradise Criteria)
- chronic tonsillitis with halitosis (bad breath) or sore throat ± tonsilloliths (clusters of calcified material that form in the crevices of the tonsils)
- complications of tonsillitis: quinsy/peritonsillar abscess, parapharyngeal abscess, retropharyngeal abscess
- failure to thrive

Relative Contraindications
- velopharyngeal insufficiency: overt or submucous/covert cleft of palate, impaired palatal function due to neurological or neuro-muscular abnormalities
- hematologic: coagulopathy, anemia
- infectious: active local infection without urgent obstructive symptoms

Complications
- hemorrhage: early – within 24 h; delayed – 7-10 d
- odynophagia and/or otalgia; dehydration
- infection
- atlantoaxial subluxation (Grisel’s syndrome): rare

Airway Problems in Children

Differential Diagnosis by Age Group

Neonates (obligate nose breathers)
- extralaryngeal:
  - choanal atresia (e.g. CHARGE syndrome)
  - nasopharyngeal dermoid, glioma, encephalocele
  - glossoptosis: Pierre-Robin sequence, Down syndrome, lymphatic malformation, hemangioma
- laryngeal:
  - laryngomalacia: most common cause of stridor in children
  - laryngocele
  - vocal cord palsy (due to trauma or Arnold-Chiari malformation)
  - glottic web
  - subglottic stenosis
  - laryngeal cleft
- tracheal:
  - tracheoesophageal fistula
  - tracheomalacia
  - vascular rings

2 to 3 Months
- congenital:
  - laryngomalacia
  - vascular: subglottic hemangioma (more common), innominate artery compression, double aortic arch
  - laryngeal papilloma
- acquired:
  - subglottic stenosis: post intubation
  - tracheal granulation: post intubation
  - tracheomalacia: post tracheotomy and TEF repair
Infants – Sudden Onset
- foreign body aspiration
- croup
- bacterial tracheitis
- caustic ingestion
- epiglottitis

Children and Adults
- infection:
  - Ludwig's angina
  - peritonsillar/parapharyngeal abscess
  - retropharyngeal abscess
- neoplastic:
  - squamous cell carcinoma (SCC) (adults): larynx, hypopharynx
  - retropharyngeal: lymphoma, neuroblastoma
  - nasopharyngeal: carcinoma, rhabdomyosarcoma
- allergic:
  - angioneurotic edema
  - polyps (suspect cystic fibrosis in children)
- trauma:
  - laryngeal fracture, facial fracture
  - burns and lacerations
  - post-intubation
  - caustic ingestion
- congenital:
  - lingual thyroid/tonsil

Signs of Airway Obstruction

Stridor
- note quality, timing (inspiratory or expiratory)
- body position important:
  - lying prone: subglottic hemangioma, double aortic arch
  - lying supine: laryngomalacia, glossophtosis
- site of stenosis:
  - vocal cords or above: inspiratory stridor
  - subglottis and extrathoracic trachea: biphasic stridor
  - distal tracheobronchial tree: expiratory stridor

Respiratory Distress
- nasal flaring
- supraclavicular and intercostal indrawing
- sternal retractions
- use of accessory muscles of respiration
- tachypnea
- cyanosis
- altered LOC

Feeding Difficulty and Aspiration
- supraglottic lesion
- laryngomalacia
- vocal cord paralysis
- laryngeal cleft g aspiration pneumonia
- TEF

Acute Laryngotracheobronchitis (Croup)
- inflammation of tissues in subglottic space ± tracheobronchial tree
- swelling of mucosal lining and associated with thick, viscous, mucopurulent exudate which compromises upper airway (subglottic space narrowest portion of upper airway)
- normal function of ciliated mucous membrane impaired

Etiology
- viral: parainfluenzae I (most common), II, III, influenza A and B, RSV
Clinical Features
- age: 4 mo to 5 yr
- preceded by URTI symptoms
- generally occurs at night
- biphasic stridor and croupy cough (loud, sea-lion bark)
- appear less toxic than epiglottitis
- supraglottic area normal
- rule out foreign body and subglottic stenosis
- ’steeple-sign’ on AP x-ray of neck
- if recurrent croup, think subglottic stenosis

Treatment
- racemic epinephrine via nebulizer q1-2h, prn (only if in respiratory distress)
- systemic corticosteroids (e.g. dexamethasone, prednisone)
- adequate hydration
- close observation for 3 to 4 h
- intubation if severe
- hospitalize if poor response to steroids after 4 h and persistent stridor at rest
- consider alternate diagnosis if poor response to therapy (e.g. bacterial tracheitis)
- if recurrent episodes of croup-like symptoms, consider bronchoscopy several weeks after acute episode settles to rule out underlying subglottic stenosis

Acute Epiglottitis
- acute inflammation causing swelling of supraglottic structures of the larynx without involvement of vocal cords

Etiology
- H. influenzae type B
- relatively uncommon condition due to Hib vaccine

Clinical Features
- any age, most commonly 1 to 4 yr
- rapid onset
- toxic-looking, fever, anorexia, restlessness
- cyanotic/pale, inspiratory stridor, slow breathing, lungs clear with decreased air entry
- prefers sitting up, open mouth, drooling, tongue protruding, sore throat, dysphagia

Investigations and Management
- investigations and physical examination may lead to complete obstruction, thus preparations for intubation or tracheotomy must be made prior to any manipulation
- stat ENT/anesthesia consult(s)
- WBC (elevated), blood and pharyngeal cultures after intubation
- lateral neck radiograph (only done if patient stable)

Treatment
- secure airway
- IV access with hydration
- antibiotics: IV cefuroxime, cefotaxime, or ceftriaxone
- moist air
- extubate when leak around tube occurs and afebrile
- watch for meningitis

Subglottic Stenosis

Congenital
- diameter of subglottis <4 mm in neonate (due to thickening of soft tissue of subglottic space or maldevelopment of cricoid cartilage)

Acquired
- following prolonged, repeated or traumatic intubation:
  - most commonly due to endotracheal intubation; nasal intubation is less traumatic and preferred in long term intubation as it puts less pressure on the subglottis (tube sits at different orientation) and there is less movement
  - subglottic stenosis is related to duration of intubation and pressure of the endotracheal tube cuff
- can also be due to foreign body, infection (e.g. TB, diphtheria, syphilis) or chemical irritation

Clinical Features
- biphasic stridor
- respiratory distress
- recurrent/prolonged croup

Diagnosis
- rigid laryngoscopy and bronchoscopy
Treatment
• if soft stenosis: divide tissue with knife or laser, dilate with balloon ± steroids
• if firm stenosis: laryngotracheoplasty

Laryngomalacia
• short aryepiglottic folds, omega-shaped epiglottis, pendulous mucosa
• caused by indrawing of supraglottis on inspiration leading to laryngopharyngeal reflux of acid

Clinical Features
• high-pitched inspiratory stridor at 1 to 2 wk
• constant or intermittent and more pronounced supine
• usually mild but when severe can be associated with cyanosis or feeding difficulties, leading to failure to thrive

Treatment
• observation is usually sufficient as symptoms spontaneously subside by 12 to 18 mo in >90% of cases
• in the case of severe laryngomalacia, division of the aryepiglottic folds (supraglottoplasty) provides relief

Foreign Body

Ingested
• usually stuck at cricopharyngeus
• coins, toys, batteries (emergency)
• presents with drooling, dysphagia, stridor if very large

Aspirated
• usually stuck at right mainstem bronchus
• peanuts, carrot, apple core, popcorn, balloons
• presentation
  ▪ stridor if lodged in trachea
  ▪ unilateral "asthma" if bronchial, therefore often misdiagnosed as asthma
  ▪ if totally occludes airway: cough, lobar pneumonia, atelectasis, mediastinal shift, pneumothorax, death

Diagnosis and Treatment
• any patient with suspected foreign body should be kept NPO immediately
• inspiration-expiration chest x-ray (if patient is stable)
• bronchoscopy or esophagoscopy with removal
• rapid onset, not necessarily febrile or elevated WBC

Deep Neck Space Infection

• most commonly arise from an infection of the mandibular teeth, tonsils, parotid gland, deep cervical lymph nodes, middle ear, or the sinuses
• often a rapid onset and may progress to fatal complications

Etiology
• usually mixed aerobes and anaerobes that represent the flora of the oral cavity, upper respiratory tract, and certain parts of the ears and eyes

Clinical Features
• sore throat or pain and trismus
• dysphagia and odynophagia
• stridor and dyspnea
• late findings may include dysphonia and hoarseness
• swelling of the face and neck, erythema
• asymmetry of the oropharynx with purulent oral discharge
• lymphadenopathy

Diagnosis
• lateral cervical view plain radiograph
• CT
• MRI

Treatment
• secure the airway
• surgical drainage
• maximum doses of IV systemic antimicrobials regimens according to the site of infection
### Common Medications

#### Table 20. Antibiotics

<table>
<thead>
<tr>
<th>Generic Name (Brand Name)</th>
<th>Dose</th>

### Primary Care

**Visit Overview**

- **schedule:**
  - newborn (within 1 wk post-discharge), 1, 2, 4, 6, 9, 12, 15, 18, 24 mo
  - annually between age 2 to 6; every other year between age 6 to 11
- **content:**
  - history and physical exam including growth, development, and nutrition
  - routine immunization
  - counseling and anticipatory guidance

### Acronyms

**AAP** American Association of Pediatrists  
**ALPS** autoimmune lymphoproliferative syndrome  
**ADHD** attention deficit hyperactivity disorder  
**ARDS** acute respiratory distress syndrome  
**ASD** atrial septal defect  
**ATD** antithyroid drug  
**ATN** acute tubular necrosis  
**CAS** Children's Aid Society  
**CF** cystic fibrosis  
**CHD** congenital heart defect  
**CMV** cytomegalovirus  
**CP** cerebral palsy  
**CPS** Canadian Pediatric Society  
**DI** diabetes insipidus  
**DIC** disseminated intravascular coagulopathy  
**DM** diabetes mellitus  
**DS** Down syndrome  
**EBV** Epstein-Barr virus  
**FASD** fetal alcohol spectrum disorder  
**FSH** follicle stimulating hormone  
**FTD** failure to thrive  
**GA** gestational age  
**GERD** gastroesophageal reflux disease  
**GH** growth hormone  
**GN** glomerulonephritis  
**HE** hypoxic ischemic encephalopathy  
**HSP** Henoch-Schönlein purpura  
**HUS** hemolytic-uremic syndrome  
**IBW** ideal body weight  
**ICH** intracranial hemorrhage  
**IUGR** intra-uterine growth retardation  
**IVH** intraventricular hemorrhage  
**IVIG** intravenous immunoglobulin  
**LCH** luteinizing hormone  
**LLSB** left upper sternal border  
**LRTI** lower respiratory tract infection  
**NICU** neonatal intensive care unit  
**PDA** patent ductus arteriosus  
**PKU** phenylketonuria  
**PUVA** psoralen + UVA  
**RDS** respiratory distress syndrome  
**RUSP** right upper sternal border  
**SLE** systemic lupus erythematosus  
**TPN** total parenteral nutrition  
**UMN** upper motor neuron  
**URTI** upper respiratory tract infection  
**VSD** ventricular septal defect

Vaccine Administration

- injection site:
  - infants (<12 mo): anterolateral thigh
  - children: deltoid
- timing of injection:
  - DTaP-IPV +Hib given in single injection
  - varicella and MMR vaccines given at either the same visit or separated by >4 wk (MMRV at 4-6 yr)
  - hepatatitis B vaccine given in 3 doses of 0.5 mL (0, 1, 6 mo) either at school in grade 7 (2 adult doses of 1 mL one month apart for teens) (Ontario) or at birth if at increased risk (i.e. endemic country, mother or household contact HBsAg positive)
  - HPV-4 vaccine given in 3 doses (0, 2, 6 mo) to grade 8 females in Ontario schools

Growth and Development

Growth
- growth is not linear:
  - most rapid growth during first two years and at puberty
  - tissues grow at different times
    - first two years = CNS; mid-childhood = lymphoid tissue; puberty = gonads
- measurement of growth:
  - premature infants (<37 wk) use corrected gestational age until age 2 yr
  - body proportion = upper / lower segment ratio (use symphysis pubis as midpoint)
    - newborn = 1.7, adult male = 0.97, adult female = 1.0

Vaccination in Cases of Asplenia or Hyposplenia (such as Sickle Cell Disease)
- Should receive all routine immunizations, including the yearly influenza vaccine
- No vaccines are contraindicated
- Susceptible to infection by encapsulated bacteria (S. pneumoniae, H. influenzae, N. meningitidis)
- For meningococcal, pneumococcal and Haemophilus influenzae b vaccines: regular vaccination in infancy according to recommended immunization schedules, PLUS:
  - Meningococcal vaccination:
    - Meningococcal-C-Conjugate at age ≥2 yr + Quadrivalent Men-P-ACWYW at least 2 wk later
    - Booster of Men-P-ACWYW q2-5 yr
  - Pneumococcal vaccination:
    - Pneumococcal polysaccharide vaccine (Pneu-P-23) at age ≥2 yr
    - Single booster of Pneu-P-23 at age ≥3 yr
  - Haemophilus influenzae type b vaccination:
    - Consider single booster at age ≥5 yr

According to the CDC, the weight of currently available scientific evidence does not support the hypothesis that MMR vaccine causes either autism or IBD. The landmark paper linking autism to the MMR vaccine (Lancet 1998;351:637-641) was retracted due to false claims in the article (Lancet 2010;375:445).

Safety and Efficacy of an Attenuated Vaccine against Severe Rotavirus Gastroenteritis
NEJM 2006;354:11-22
Study: Randomized, double-blind, phase 3 trial. Patients: 83,256 healthy infants from Latin America and Finland.
Intervention: Two oral doses of HRV vaccine vs. placebo at 2 and 4 mo of age.
Outcome: Episodes of gastroenteritis and severity
Results: The vaccine is 85% efficacious against severe rotavirus gastroenteritis and hospitalizations associated with gastroenteritis and 100% efficacious against more severe gastroenteritis.
Average Growth Parameters

Table 3. Parameter of Average Growth

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Normal</th>
<th>Growth</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Birth Weight</td>
<td>3.25 kg (7 lbs)</td>
<td>Gain 20-30 g/d (term neonate)</td>
<td>Weight loss (up to 10% of birth wt) in first 7 d of life is normal. Neoneate should regain birth weight by ~10-14 d of age.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 x birth wt by 4-5 mo</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 x birth wt by 1 yr</td>

</tbody>
</table>

Reflexes

Table 4. Reflexes

<table>
<thead>
<tr>
<th>Reflex</th>
<th>Maneuver to Elicit Reflex</th>
<th>Appropriate Reflex Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moro</td>
<td>Infant placed semi-upright, head supported by examiner’s hand, sudden withdrawal of supported head with immediate resupport</td>
<td>Abduction and extension of the arms, opening of the hands, followed by flexion and adduction of arms</td>
</tr>
<tr>
<td>Galant</td>
<td>Infant held in ventral suspension and one side of back is stroked along paravertebral line</td>
<td>Pelvis will move in the direction of stimulated side</td>
</tr>
<tr>
<td>Grasp</td>
<td>Placement of examiner’s finger in infant’s palm</td>
<td>Flexion of infant’s fingers</td>
</tr>
<tr>
<td>ATNR</td>
<td>Turn infant’s head to one side</td>
<td>“Fencing” posture (extension of ipsilateral arm and arm and flexion of contralateral leg)</td>
</tr>
<tr>
<td>Placing</td>
<td>Dorsal surface of infant’s foot placed touching edge of table</td>
<td>Flexion followed by extension of ipsilateral limb up onto table (remakes primitive walking)</td>
</tr>
<tr>
<td>Rooting</td>
<td>Tactile stimulus near mouth</td>
<td>Infant pursues stimulus with face</td>
</tr>
<tr>
<td>Parachute</td>
<td>Tilt infant to side while in sitting position</td>
<td>Ipsilateral arm extension, present by 6-8 mo</td>
</tr>
</tbody>
</table>

ATNR = asymmetric tonic neck reflex

Abnormal Reflex Response

- Absence may suggest CNS abnormality
- Persistence after 4-6 mo may indicate abnormality (e.g. cerebral palsy)
- Asymmetry suggests focal motor lesions (e.g. brachial plexus injury)
- Upgoing plantar reflex (Babinski’s sign) normal in infants up to age 2 yr

Developmental Milestones

Table 5. Developmental Milestones

<table>
<thead>
<tr>
<th>Age*</th>
<th>Gross Motor</th>
<th>Fine Motor</th>
<th>Speech and Language</th>
<th>Adaptive and Social Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 month</td>
<td>Turns head side to side when supine</td>
<td>Hands fist, thumb in fist</td>
<td>Cries, startles to loud noises</td>
<td>Calms when comforted</td>
</tr>
<tr>
<td>2 months</td>
<td>Briefly raises head when prone, holds head erect when upright</td>
<td>Pulls at clothes</td>
<td>Variety of sounds (e.g. coos, gurgles)</td>
<td>Smiles responsively, recognizes and calms down to familiar voice, follows movement with eyes</td>
</tr>
<tr>
<td>4 months</td>
<td>Lifts head and chest when prone, holds head steady when supported sitting, rolls prone to supine</td>
<td>Briefly holds object when placed in hand, reaches for midline objects</td>
<td>Turns head towards sounds</td>
<td>Laughs responsively, follows moving toy or person with eyes, responds to people with excitement (e.g. leg movement)</td>
</tr>
<tr>
<td>6 months</td>
<td>Tripod sit, pivots in prone position</td>
<td>Ulnar grasp, transfers objects from hand to hand, brings objects to mouth</td>
<td>Babbles</td>
<td>Stranger anxiety, beginning of object permanence</td>
</tr>
<tr>
<td>9 months</td>
<td>Sits well without support, crawls, pulls to stand, stands with support</td>
<td>Early pincer grasp with straight wrist</td>
<td>“Mama, dada” – appropriate, imitates 1 word, responds to “no” regardless of tone</td>
<td>Plays games (e.g. peek-a-boo), reaches to be picked up</td>
</tr>
<tr>
<td>12 months</td>
<td>Gets into sitting position without help, stands without support, walks while holding on</td>
<td>Neat pincer grasp, releases ball with throw</td>
<td>2 words, follows 1-step command, uses facial expression, sounds, actions to make needs known</td>
<td>Responds to own name, separation anxiety begins</td>
</tr>
</tbody>
</table>

Scoliosis Screening

Despite mass school screening implemented in parts of the USA and Canada in the 1970s-90s, the Canadian (1994) and American (2004) Task Forces on Preventive Health Care do NOT currently recommend routine screening using the Forward Bend Test (FBT). Cohort studies indicate that the forward bend test has poor sensitivity for identifying pathological curves. Furthermore, there is no evidence to suggest that screening and increased bracing lead to better outcomes.

Pediatric Developmental Milestones

- 1 yr: single words
- 2 yr: 2-word sentences; understands 2 step commands
- 3 yr: 3-word combinations; rides tricycle
- 4 yr: counts 4 objects

*Use corrected gestational age until 2 yr
Table 5. Developmental Milestones (continued)

<table>
<thead>
<tr>
<th>Age*</th>
<th>Gross Motor</th>
<th>Fine Motor</th>
<th>Speech and Language</th>
<th>Adaptive and Social Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 months</td>
<td>Walks without support, crawls up stairs/steps</td>
<td>Picks up and eats finger foods, scribbles, stacks 2 blocks</td>
<td>Says 4-5 words, points to needs/wants</td>
<td>Looks to see how others react (e.g. after falling)</td>
</tr>
<tr>
<td>18 months</td>
<td>Runs, walks forward pulling toys or carrying objects</td>
<td>Tower of 3 cubes, scribbling, eats with spoon</td>
<td>10 words, follows simple commands</td>
<td>Show affection towards others, points to show interest in something</td>
</tr>
<tr>
<td>24 months</td>
<td>Climbs up 2 feet per step, runs, kicks ball, walks up and down steps</td>
<td>Tower of 6 cubes, undresses</td>
<td>2-3 word phrases, uses “I, me, you”, 50% intelligible, understands 2-step commands</td>
<td>Parallel play, helps to dress</td>
</tr>
<tr>
<td>3 years</td>
<td>Tricycle, climbs up 1 foot per step, down 2 feet per step, stands on one foot briefly</td>
<td>Copies a circle, turns pages one at a time, puts on shoes, dress/undress fully except buttons</td>
<td>Combines 3 or more words into sentence, recognizes colors, prepositions, plurals, counts to 10, 75% intelligible</td>
<td>Knows sex, age, shares some of the time, plays make-believe games</td>
</tr>
<tr>
<td>4 years</td>
<td>Hops on 1 foot, down 1 foot per step</td>
<td>Copies a cross, uses scissors, buttons clothes</td>
<td>Speech intelligible, uses past tense, 100% intelligible, understands 3-part directions</td>
<td>Cooperative play, fully toilet-trained by day, tries to comfort someone who is upset</td>
</tr>
<tr>
<td>5 years</td>
<td>Skips, rides bicycle</td>
<td>Copies a triangle and square, prints name, ties shoelaces</td>
<td>Fluent speech, future tense, alphabet, retells sequence of a story</td>
<td>Cooperates with adult requests most of the time, separates easily from caregiver</td>
</tr>
</tbody>
</table>

*Use corrected gestational age until 2 yr

**Nutrition**

**Dietary Requirement**

<table>
<thead>
<tr>
<th>Weight</th>
<th>&lt;10 kg</th>
<th>10-20 kg</th>
<th>&gt;20 kg</th>
</tr>
</thead>
<tbody>
<tr>
<td>kcal</td>
<td>100 kcal/kg/d</td>
<td>1000 kcal + 50 kcal/kg/d for each kg &gt;10</td>
<td>1500 kcal + 20 kcal/kg/d for each kg &gt;20</td>
</tr>
</tbody>
</table>

**Dietary Recommendations**

- 0 to 6 months: breast milk or formula
  - exclusive breast milk during first 6 mo recommended over formula unless contraindicated
  - breastfed infants require supplements: vitamin K (all babies get at birth, breastfed or not), vitamin D (400-800 IU/d), fluoride (after 6 mo if not sufficient in water), iron (6-12 mo, only if not receiving fortified cereals/meat/meat alternatives)
- >6 months: solid food introduction – do not delay beyond 9 mo
  - 2 to 3 new foods per week with a few days in between each food to allow time for adverse reaction identification
  - suggested order of introduction:
    - meat, meat alternatives, and iron enriched cereal (rice cereal is least allergenic)
    - pureed vegetables
    - fruit
  - 9 to 12 months: finger foods and switch to homogenized (3%) milk
    - foods to avoid:
      - honey until past 12 mo (risk of botulism)
      - added sugar, salt
      - excessive milk (i.e. no more than 16 oz/d after a yr)
      - juice (not nutritious, too much sugar)
      - anything that is a choking hazard (chunks, round foods like grapes)

**Breastfeeding**

- content of breast milk:
  - colostrum (first few days): clear, rich in nutrient (i.e. high protein, low fat), immunoglobulin
  - mature milk: 70:30 whey:casein ratio, fat from dietary butterfat, carbohydrate from lactose
- advantages:
  - easily digested, low renal solute load
  - immunologic
    - contains IgA, macrophages, active lymphocytes, lysozymes, lactoferrin (which inhibits E. coli growth in intestine)
    - lower pH promotes growth of lactobacillus in GI tract
  - parent-child bonding
  - economical, convenient
• contraindicated if mother:
  • is receiving chemotherapy or radioactive compounds
  • has HIV/AIDS, active untreated TB, herpes in breast region
  • is using >0.5 g/kg/d alcohol or illicit drugs
  • is taking medications known to cross to breast milk
  • oral contraceptive pills *not* a contraindication to breastfeeding (estrogen may decrease lactation, but is not dangerous to infant)
  • MotherRisk – valuable research and counselling on reproductive risk or safety of drugs, chemicals, and maternal disease

complications in infant:
• breastfeeding jaundice (first 1-2 wk): due to lack of milk production and subsequent dehydration (see jaundice, P73), likely mechanical problem
• breast milk jaundice (0.5% of newborns, persists up to 4-6 mo): rare, not fully understood, thought to be due to substances in breast milk that inhibit conjugation of bilirubin or increase enterohepatic circulation of bilirubin, likely a biochemical problem. Check bilirubin rule out conjugated hyperbilirubinemia.
  • baby presents healthy and thriving, and jaundice resolves
  • poor weight gain: consider dehydration or failure to thrive
  • oral candidiasis (thrush): check baby’s mouth for white cheesy material that does not scrape off; treat baby with antifungal such as nystatin (Mycostatin®) (treat mother topically to prevent transmission). Can occur in breast or bottle-fed infants.

### Table 6. Formula Compared to Breast Milk

<table>
<thead>
<tr>
<th>Type of Nutrition</th>
<th>Indications</th>
<th>Content (as compared to breast milk)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cow’s milk based</strong> (Enfamil®, Similac®)</td>
<td>Prematurity Transition into breastfeed Contraindication to breastfeed</td>
<td>Lower whey:casein ratio Plant fats instead of dietary butterfat</td>
</tr>
<tr>
<td><strong>Fortified formula</strong></td>
<td>Low birth weight Prematurity</td>
<td>Higher calories and vitamins A, C, D, K May only be used in hospital due to risk of fat-soluble vitamin toxicity</td>
</tr>
<tr>
<td><strong>Soy protein</strong> (Isomil®, Prosobee®)</td>
<td>Galactosemia Lactose intolerance (note: true lactose intolerance rare in children under age 5)</td>
<td>Corn syrup solids or sucrose in place of lactose</td>
</tr>
<tr>
<td><strong>Partially hydrolyzed proteins</strong> (Good Start®)</td>
<td>Delayed gastric emptying Risk of cow’s milk allergy</td>
<td>Protein is 100% whey with no casein</td>
</tr>
<tr>
<td><strong>Protein hydrolysate</strong> (Nutramigen®, Alimentum®, Pregestimil®, Portagen®)</td>
<td>Malabsorption Food allergy</td>
<td>Protein is 100% casein with no whey Cori syrup solids, sucrose or tapioca starch instead of lactose Expensive</td>
</tr>
<tr>
<td><strong>Amino acid</strong> (Neocate®)</td>
<td>Food allergy Short gut</td>
<td>Free amino acids (no protein) Cori syrup solids instead of lactose Very expensive</td>
</tr>
<tr>
<td><strong>Metabolic</strong></td>
<td>Inborn errors of metabolism</td>
<td>Various different compositions for children with galactosemia, propionic acidemia, etc.</td>
</tr>
</tbody>
</table>

### Injury Prevention Counselling

- injuries are the leading cause of death in children >1 yr of age
- main causes: motor vehicle crashes, burns, drowning, falls, choking, infanticide

### Table 7. Injury Prevention Counselling

<table>

</tbody>
</table>
Common Complaints

Breath Holding Spells

- epidemiology: 0.1-5% of healthy children 6 mo-4 yr of age, usually start during first year of life
- etiology: child is provoked (usually by anger, injury, or fear) → holds breath and becomes silent
  - spontaneously resolves or loses consciousness
- types:
  - cyanotic (more common), usually associated with anger/frustration
  - pallid, usually associated with pain/surprise
- management:
  - usually resolves spontaneously and rarely progresses to seizure
  - help child control response to frustration and avoid drawing attention to spell

Circumcision

- elective procedure
  - not covered by OHIP in Ontario, but recent evidence shows health benefits outweigh risks and justify access to procedure
  - often for religious or culture reasons
- benefits: prevention of phimosis and slightly reduced incidence of UTI, balanitis, cancer of the penis
- complications (<1%): local infection, bleeding, urethral injury
- contraindications: presence of genital abnormalities (e.g. hypospadias) or known bleeding disorder

Crying/Fussing Child

- history:
  - description of baseline feeding, sleeping, crying patterns
  - infectious symptoms: fever, tachypnea, rhinorrhea, ill contacts
  - feeding intolerance: gastroesophageal reflux with esophagitis, nausea, vomiting, diarrhea, constipation
  - trauma
  - recent immunizations (vaccine reaction) or medications (drug reactions), including maternal drugs taken during pregnancy (neonatal withdrawal syndrome) and drugs that may be transferred via breast milk
  - inconsistent history, pattern of numerous emergency department visits, high-risk social situations all raise concern of abuse

Dentition and Caries

Dentition
- primary dentition (20 teeth)
  - first tooth at 5-9 mo (lower incisor), then 1 per month
  - 6-8 central teeth by 1 yr
  - assessment by dentist 6 mo after eruption of first tooth and certainly by 1 yr of age (Grade B recommendation)
- secondary dentition (32 teeth)
  - first adult tooth is 1st molar at 6 yr, then lower incisors

Caries
- milk caries: decay of superior front teeth and back molars in first 4 yr of life
- cause: often due to prolonged feeding (e.g. put to bed with bottle, prolonged breastfeeding)
- prevention:
  - no bottle at bedtime, clean teeth after last feed
  - minimize juice and sweetened pacifier
  - clean teeth with soft damp cloth or toothbrush and water
  - water fluoridation

Enuresis

Definition
- involuntary urinary incontinence by day and/or night in child >5 yr

General Approach
- should be evaluated if dysuria, change in colour, odour, stream, secondary or diurnal, change in gait, stool incontinence

Primary Nocturnal Enuresis
- definition: wet only at night during sleep, bladder control has never been attained
- epidemiology: boys > girls; 10% of 6 yr olds, 3% of 12 yr olds, 1% of 18 yr olds
- etiology: developmental disorder or maturational lag in bladder control while asleep
- management:
  - time and reassurance (~20% resolve spontaneously each yr)
  - behaviour modification (limiting fluids, voiding prior to sleep), bladder retention exercises, scheduled toileting has limited effectiveness
  - conditioning: "wet" alarm wakes child upon voiding (70% success rate)
  - medications (considered second line therapy, may be used for sleepovers/camp): DDAVP oral tablets (high relapse rate, costly), imipramine ('Tofranil') (rarely used, lethal if overdose, cholinergic side effects)

Secondary Enuresis
- definition: develops after child has sustained period of bladder control (>6 mo)
- etiology: inorganic regression due to stress or anxiety (e.g. birth of sibling, significant loss, family discord), focused on other activities, secondary to organic disease (UTI, DM, DI, neurogenic bladder, cerebral palsy (CP), sickle cell disease, seizures, pinworms)
- management: treat underlying cause

Diurnal Enuresis
- definition: daytime wetting (60-80% also wet at night)
- etiology: micturition deferral (holding urine until last minute) due to psychosocial stressor (e.g. shy), structural anomalies (e.g. ectopic ureteral site, neurogenic bladder), UTI, constipation, CNS disorders
- management: treat underlying cause, behavioural (scheduled toileting, double voiding, good bowel program), pharmacotherapy

Encopresis
- definition: fecal incontinence in a child >4 yr old, at least once per month for 3 months
- prevalence: 1-1.5% of school-aged children (rare in adolescence); M:F = 6:1 in school-aged children
- causes: chronic constipation (retentive encopresis), Hirschsprung disease, hypothyroidism, hypercalcemia, spinal cord lesions, anorectal malformations
Retentive Encopresis
• definition
  • child holds bowel movement, develops constipation, leading to fecal impaction and seepage of soft or liquid stool (overflow incontinence)
• etiology
  • physical: painful stooling often secondary to constipation
  • emotional: disturbed parent-child relationship, coercive toilet training, social stressors
• clinical presentation
  • history
    • crosses legs or stands on toes to resist urge to defecate
    • distressed by symptoms, soiling of clothes
    • toilet training coercive or lacking in motivation
    • may show oppositional behavior
    • abdominal pain
  • physical exam
    • digital rectal exam: large fecal mass in rectal vault
    • anal fissures (result from passage of hard stools)
    • palpable stool in LLQ
• management
  • complete clean-out of bowel: PEG 3350 given orally is most effective, enemas and suppositories may be second line therapies, but these are invasive and often less effective
  • maintenance of regular bowel movements (see Pediatric Gastroenterology, Constipation Treatment, P38)
  • assessment and guidance regarding psychosocial stressors
  • behavioural modification
• complications: recurrence, toxic megacolon (requires >3-12 mo to treat), bowel perforation

Failure to Thrive
• definition
  • weight <3rd percentile, or falls across two major percentile curves, or <80% of expected weight for height and age
  • inadequate caloric intake most common factor in poor weight gain
  • may have other nutritional deficiencies (e.g. protein, iron, vitamin D)
  • factors affecting physical growth: genetics, intrauterine factors, internal time clock, nutrition, endocrine hormones, chronic infections/diseases, psychosocial factors
• clinical presentation
  • history
    • nutritional intake
    • current symptoms
    • past illnesses
    • family history: growth, puberty, parental height and weight including mid-parental height
    • psychosocial history
  • physical exam
    • growth parameters, plotted: height (Ht), weight (Wt), head circumference (HC), arm span
    • vital signs
    • complete head to toe exam
    • dysmorphic features or evidence of chronic disease
    • upper to lower segment ratio
    • sexual maturity staging
    • signs of abuse or neglect
• investigations (as indicated by clinical presentation)
  • CBC, blood smear, electrolytes, T4, TSH, GH, IGF-1
  • bone age x-ray
  • chromosomes/karyotype
  • chronic illness: chest (CXR, sweat Cl-), cardiac (CXR, ECG, ECHO), GI (celiac screen, inflammatory markers, malabsorption), renal (urinalysis), liver (enzymes, albumin)
• Energy Requirements
  • 0-10 kg: 100 kcal/kg/d
  • 1-20 kg: 1,000 kcal + 50 kcal/kg/d for each kg >10
  • >20 kg: 1,500 kcal + 20 kcal/kg/d for each kg >20
• Calculating Upper to Lower (U/L) Segment Ratio
  • Upper segment: Top of head to pubic symphysis
  • Lower segment: Pubic symphysis to floor
  • U/L: upper segment/lower segment
• Upper to Lower (U/L) Segment Ratio
  • Increased in achondroplasia, short limb syndromes, hypothyroid, storage diseases
  • Decreased in Marfan’s, Klinefelter’s, Kallman’s syndromes, and testosterone deficiency
• Mid-Parental Height (MPH)
  • Boys target height = (father ht + mother ht + 13)/2
  • Girls target height = (father ht + mother ht -13)/2

</tr>
<tr>
<td>Constitutional Growth Delay (BA &lt; CA)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

BA=bone age; CA=chronological age
**Energy Requirements**
- see Nutrition, P6

**Infantile Colic**
- definition: unexplained paroxysms of irritability and crying for >3 h/d, >3 d/wk for >3 wk in an otherwise healthy, well-fed baby (rule of 3s)
- epidemiology: 10% of infants; usual onset 10 d to 3 mo of age with peak at 6-8 wk
- etiology: lag in development of normal peristaltic movement in gastrointestinal tract; other theories suggest a lack of self-soothing mechanisms or extreme of normal
- management:
  - parental relief, rest and reassurance
  - hold baby, soother, car ride, music, vacuum, check diaper
  - medications (Ovol® drops, gripe water) have no proven benefit, some evidence for probiotics
  - if breastfeeding, elimination of cow's milk protein from mother's diet (effective in very small percentage of cases)
  - try casein hydrosylates formula (Nutramigen®)
  - if breastfeeding is not possible, consider formula
  - time – all resolve, most in the first 2-3 mo of life

**Obesity**
- definition: BMI >95th percentile for age and height
- risk factors: genetic predisposition (e.g. both parents obese – 80% chance of obese child)
- etiology: organic causes are rare (<5%): Prader-Willi, Carpenter, Turner, Cushing syndromes, hypothryoidism
- complications: association with hypertension, dyslipidemia, slipped capital femoral epiphysis, type 2 diabetes, asthma, obstructive sleep apnea, gynecomastia, polycystic ovarian disease, early menarche, irregular menses, psychological trauma (e.g. teasing, decreased self-esteem, unhealthy coping mechanisms, depression)
- childhood obesity is not reliable predictor of adult obesity unless >180% ideal body weight, adolescent obesity good predictor of adult obesity
- management:
  - encouragement and reassurance; engagement of entire family
  - diet: qualitative changes (do not encourage weight loss, but allow for linear growth to catch up with weight), special diets used by adults are not encouraged
  - very low calorie diets for preadolescents are not recommended
  - behaviour modification: increase activity, change eating habits/meal patterns
  - education: multidisciplinary approach, dietitian, counselling
  - surgery and pharmacotherapy are not frequently used in children
  - increase activity; reduce screen time
Poison Prevention

- keep all types of medicines, vitamins, and chemicals locked up in a secure container
- potentially dangerous: drugs, drain cleaners, furniture polish, insecticides, cosmetics, nail polish remover, automotive products
- do not store any chemicals in juice, soft drink, or water bottles
- keep alcoholic beverages out of reach: 3 oz hard liquor can kill a 2-yr-old
- always read labels before administering medicine to ensure correct drug and dose

Rashes

<td>Antifungal agents</td>
</tr>
</tbody>
</table>

Other Dermatitis

- Atopic dermatitis
  - Erythematous papules/plaques, oozing, excoriation, lichenification, classic areas of involvement
  - Eliminate exacerbating factors, maintain skin hydration, corticosteroids, topical calcineurin inhibitor
- Nummular dermatitis
  - Annular erythematous plaques, oozing, crust
  - Avoid irritant if identified, potent topical steroid in emollient base, short-term systemic steroids ± antibiotics (severe)
- Allergic contact dermatitis
  - Red papules/plaques-vesicles/bullaes, only in area of allergen
  - Mild: soothing lotion (i.e. calamine lotion)
  - Moderate: topical moderate/strong potency
  - Severe: systemic corticosteroids and antihistamine
- Irritant contact dermatitis
  - Morphology depends on irritant
  - Avoid skin contact
- Dyshidrotic dermatitis
  - Papulovesicular, cracking/fissuring, hands and feet (“Tapioca pudding”)
  - Mild/Moderate: medium/potent topical corticosteroids
  - Severe: systemic corticosteroids, local PUVA or UVA treatments
- Seborrheic dermatitis
  - See above, sebaceous areas such as nasolabial folds and scalp

Infectious

- Scabies
  - Polyomorphic (red excoriated papules/nodules, burrows), in web spaces/folds, very pruritic
  - Permethrin (Nix) 5% cream for patient and family (2 applications, 1 wk apart)
- Impetigo
  - Honey-coloured crusts or superficial bullae
  - Oral antibiotics (e.g. cephalaxin/erythromycin)
  - Topical if mild: fucidic acid or mupirocin cream
- Tinea corporis
  - Round erythematous plaques, central clearing and scaly border
  - Topical anti-fungal for skin, systemic anti-fungals for nails/head

Pediatric Exanthems (see Infectious Pediatric Exanthems, P58, Dermatology, D40)

Drug Reactions (see Dermatology, D22)

Acne (see Dermatology, D11)

Sleep Disturbances

Types of Sleep Disturbances

- insufficient sleep quantity
  - difficulty falling asleep (e.g. Limit Setting Sleep Disorder)
    - preschool and older children
    - bedtime resistance
    - due to caregiver’s inability to set consistent bedtime rules and routines
    - often exacerbated by child’s oppositional behaviours
• poor sleep quality
  ▪ frequent arousals (e.g. sleep-onset association disorder)
  ▪ child learns to fall asleep only under certain conditions or associations (with parent, held, rocked or fed, with light on, in front of television), and child loses ability to self-soothe
  ▪ during the normal brief arousal periods of sleep (90-120 min), child cannot fall back asleep because same conditions are not present
• obstructive sleep apnea
  ▪ epidemiology: 1-5% of preschool aged children, more common in black children
  ▪ definition: partial or intermittent complete airway obstruction during sleep causing disrupted ventilation and sleep pattern
  ▪ features: snoring/gasping/noisy breathing during sleep and irritable/tired/hyperactive during the day
  ▪ sequelae: cardiovascular (hypertension/LV remodeling due to sympathetic activation), growth, cognitive, and behavioural deficits
  ▪ risk factors: adenotonsillar hypertrophy, obesity
  ▪ management: watchful waiting, weight reduction, airway pressure devices, or surgery depending on the cause
  ▪ adenotonsillectomy does not improve executive function or attention but reduces symptoms and improves behaviour, quality of life, and polysomnographic findings
• parasomnias
  ▪ episodic nocturnal behaviours
  ▪ often involves cognitive disorientation and autonomic/skeletal muscle disturbance
  ▪ e.g. sleep walking, sleep terrors, nightmares

Management of Sleep Disturbances
• set strict bedtimes and “wind-down” routines
• do not send child to bed hungry
• positive reinforcement for limit setting sleep disorder
• always sleep in bed, in a dark, quiet, and comfortable room, without associations
• do not use bedroom for timeouts
• systematic ignoring and gradual extinction for sleep onset association disorder

Nightmares
• epidemiology: common in boys, 4-7 yr old
• associated with REM sleep (anytime during night)
• features: upon awakening, child is alert and clearly recalls frightening dream
  ▪ ± associated with daytime stress/anxiety
• management: reassurance

Night Terrors
• epidemiology: 15% of children have occasional episodes
• abrupt sitting up, eyes open, screaming
• clinical features: occurs in early hours of sleep, stage 4 of sleep; signs of panic and autonomic arousal, no memory of event, unconsolable, stress/anxiety can aggravate them
• course: remits spontaneously at puberty
• management: reassurance for parents, ensure child is safe (e.g. if sleepwalks)

Toilet Training
• 90% of children attain bladder control before bowel control
• generally females train earlier than males
• 25% by 2 yr old (in North America), 98% by 3 yr old have daytime bladder control
• signs of toilet readiness:
  ▪ ambulating independently, stable on potty, desire to be independent or to please caregivers (i.e. motivation), sufficient expressive and receptive language skills (2-step command level), can stay dry for several hours (large enough bladder), can recognize need to go, able to remove clothing

Sudden Infant Death Syndrome (SIDS)

Definition
• sudden and unexpected death of an infant <12 mo of age in which the cause of death cannot be found by history, examination, or a thorough postmortem and death scene investigation

Epidemiology
• 0.5/1000 (leading cause of death between 1-12 mo of age); M:F = 3:2
• more common in children placed in prone position
• in full term infants, peak incidence is 2-4 mo, 95% of cases occur by 6 mo
• increase in deaths during peak respiratory syncytial virus (RSV) season
• most deaths occur between midnight and 8 AM
Risk Factors
• prematurity, smoking in household, socially disadvantaged, higher incidence in aboriginals and African Americans
• risk of SIDS is increased 3-5x in siblings of infants who have died of SIDS

Prevention
• “Back to Sleep, Front to Play” (place infant on back when sleeping)
• allow supervised play time daily in prone position (‘tummy time’)
• alarms, monitors not recommended – increase anxiety, do not prevent life-threatening events
• avoid overheating and overdressing
• appropriate infant bedding (firm mattress, avoid loose bedding and crib bumper pads)
• no smoking
• risks associated with bedsharing: sleeping on a sofa, sleeping with an infant after consumption of alcohol/street drugs, infant sleeping with someone other than primary caregiver
• pacifiers appear to have a protective effect; do not reinsert if falls out

Child Abuse and Neglect

Definition
• an act of commission (physical, sexual, or psychological abuse) or omission (neglect) by a caregiver that harms a child

Legal Duty to Report
• upon reasonable grounds to suspect abuse and/or neglect, physicians are required by legislation to contact the Child Protective Services (CPS) to personally disclose all information relevant to the child safety concern
• duty to report overrides patient confidentiality; physician is protected against liability

Ongoing Duty to Report
• if there are additional reasonable grounds to suspect abuse and/or neglect, a further report to the CPS must be made

Risk Factors
• environmental factors: social isolation, poverty, domestic violence
• caregiver factors: personal history of abuse, psychiatric illness, substance abuse, single parent family, poor social and vocational skills, below average intelligence
• child factors: difficult temperament, disability, special needs (e.g. developmental delay), premature

Physical Abuse

History
• history that is not compatible with physical findings, or history not reproducible
• delay in seeking medical attention that is unexplained by other factors

Physical Exam
• physical findings not explained by underlying medical condition
• growth parameters (weight, height, head circumference)
• recurrent or multiple injuries not explained by accidental injury or child’s development level
• patterned skin injuries: belt buckle, hand prints, burns that do not match provided history
• injury location: bruises on areas with abundant soft-tissue cushioning, such as abdomen, buttocks, genitalia, fleshy part of cheek; bruises on ears; posterior rib/metaphyseal/scapular/vertebral/skeletal fractures (more suspicious for non-accidental injuries); immersion burns (e.g. hot water)
• altered mental status: head injury, poisoning
• head trauma is the leading cause of death in child maltreatment [e.g. acceleration-deceleration forces (shaking), direct force application (blow or impact)]

Investigations
• document all injuries on a body diagram: type, location, size, shape, colour, pattern
  • photography of skin injuries is ideal (police or hospital photography preferred; do not use physician’s personal camera)
• blood tests to rule out medical causes (e.g. thrombocytopenia or coagulopathy)
• screen for abdominal trauma (transaminases and amylase): if increased, abdo CT recommended
• skeletal survey in children <2 yr:
  • bone scan can be beneficial for assessing rib fractures (not helpful for skull or metaphyseal region due to active bone growth) – consider bone scan if equivocal findings on initial skeletal survey
  • dilated eye examination by pediatric ophthalmologist to rule out retinal hemorrhage
• be aware of “red herrings” (e.g. Mongolian blue spots vs. bruises)
• neuroimaging: CT and/or MRI

Apparent Life-Threatening Events (ALTEs)
A group of conditions often marked by an episode of apnea, cyanosis, change in tone, or change in mental status occurring in a child, where an observer fears the child may be dying. There is no clear connection between most ALTEs and SIDS. Evaluating for a cause of the ALTE (e.g. infection, cardiac, neurologic) is guided by history, physical examination and period of observation.

Presentation of Neglect
• Failure to thrive, developmental delay
• Inadequate or dirty clothing, poor hygiene
• Child exhibits poor attachment to parents, no stranger anxiety

“If no cruising, no bruising.”
Sexual Abuse

Epidemiology
• peak ages at 2-6 and 12-16 yr
• most perpetrators are male and known to child
  ▪ in decreasing order: family member, non-relative known to victim, stranger

History
• diagnosis usually depends on child disclosing to someone or forensic interview done by a
  trained individual
• psychosocial: specific or generalized fears, depression, nightmares, social withdrawal, lack of
  trust, low self-esteem, school failure, sexually aggressive behaviour, advanced sexual knowledge,
  sexual preoccupation or play

Physical Exam
• recurrent UTIs, pregnancy, STIs, vaginitis, vaginal bleeding, pain, genital injury, enuresis

Investigations
• depend on presentation, age, sex, and pubertal development of child
  ▪ sexual assault examination kit within 24 h if prepubertal, within 72 h if pubertal
  ▪ rule out STI, UTI, pregnancy (consider STI prophylaxis or emergency contraception)
  ▪ rule out other injuries (vaginal/anal/oral penetration, fractures, head trauma)

Neglect

History
• from child and each caregiver separately (if possible)

Physical exam
• head to toe (do not force), growth parameters, nutrition status
• dental care
• emotional state

Investigations
• blood tests to rule out medical causes (e.g. thrombocytopenia or coagulopathy)

Management of Physical Abuse, Child Abuse and Neglect
• report all suspicions to CPS; request emergency visit if imminent risk to child or any siblings in
  the home
• acute medical care: hospitalize for medical evaluation or treatment of injuries if indicated
• arrange consultation to social work and appropriate follow-up
• may need to discharge child directly to CPS or to responsible guardian under CPS supervision

Adolescent Medicine

Adolescent History (HEEADDSSS)
• tailor your history according to the clinical context

Home: Who do you live with? What kind of place do you live in?

Education/Employment: What grade are you in? What are your favourite subjects? What was
your average on your last report card?

Eating: Tell me about your meals/snacks in a typical day? Have you ever gone on a diet?
(for Eating Disorders – see Psychiatry, PS29)

Activities: What do you do after school? On the weekends? How much time do you spend on
the computer/watching TV every day? Do you use Facebook?

Drugs: Which seems to be more popular at your school, alcohol or drugs? How often do you
drink/smoke marijuana/take other drugs? Do you smoke cigarettes? When you drink, do you usu-
ally get drunk? Have you ever passed out or not been able to remember what happened while you
were drinking? Has anything bad ever happened to you while you were drunk or stoned?
(for Substance Abuse – see Psychiatry; PS21)

Sexuality: Are you romantically interested in anyone? When you think about having sex with
someone, do you think about girls, boys or both? Have you ever had sex with anyone? Whether
the answer is yes or no, the next question is: What activities would you include in the term ‘having
sex’? What do you do to prevent getting a sexually transmitted infection/getting pregnant/getting
someone pregnant? Has anyone ever given you money, drugs or other stuff in exchange for sex?
(for Sexually Transmitted Infections – see Gynecology, GY26)
**Suicidality/Depression:** On a scale of 1 to 10, where 1 is so sad that you might kill yourself and 10 is the happiest you could be, where are you most days? Is there a difference between school days and the weekend? Have you ever thought seriously about suicide? Did you make a plan? (for Depression/Suicide – see Psychiatry, PS9, PS4)

**Safety/Violence:** Do you ever get into a car with a driver who has been drinking? Do you always wear a seatbelt/bicycle helmet? Are you being bullied at school? Has anyone ever touched you in an unwanted way?

For Normal and Abnormal Pubertal Development, P31

## Cardiology

### Congenital Heart Disease (CHD)

#### PRENATAL CIRCULATION

Figure 1. Prenatal circulation

- **Embryologic Development**
  - most critical period of fetal heart development is between 3-8 wk gestation
  - single heart tube grows rapidly forcing it to bend back upon itself and assume the shape of a four chambered heart, insults at this time are most likely to lead to CHD

- **Before Birth**
  - fetal lungs are bypassed by flow through fetal shunts:
    - shunting deoxygenated blood
      - ductus arteriosus: connection between pulmonary artery and aorta
    - shunting oxygenated blood
      - foramen ovale: connection between R and L atria
      - ductus venosus: connecting between umbilical vein and IVC
  - circulation (Figure 1)

- **At Birth**
  - with first breath, lungs open up and pulmonary resistance decreases allowing pulmonic blood flow
  - separation of low resistance placenta → systemic circulation becomes a high resistance system → ductus venosus closure
  - increased pulmonic flow → increased left atrial pressures → foramen ovale closure
  - increased oxygen concentration in blood after first breath → decreased prostaglandins → ductus arteriosus closure
  - closure of fetal shunts and changes in vascular resistance → infant circulation assumes normal adult flow

Prevalence rates of depression: 1-2% in pre-pubertal children and 6-8% in adolescents.

Date rape comprises 80% of sexual assault in teenagers.

Fetal circulation is designed so that oxygenated blood is preferentially delivered to the brain and myocardium.
Epidemiology
- 8/1000 live births have CHD, which may present as a heart murmur, heart failure, or cyanosis; ventricular septal defect is the most common lesion

Investigations
- Echocardiogram, ECG, CXR

CYANOTIC VS. ACYANOTIC CONGENITAL HEART DISEASE
- cyanosis: blue mucous membranes, nail beds, and skin secondary to an absolute concentration of deoxygenated hemoglobin of at least 3 g/dL
- acyanotic heart disease: (i.e. L to R shunt, obstruction occurring beyond lungs) blood passes through pulmonic circulation → oxygenation takes place → low levels of deoxygenated blood in systemic circulation → no cyanosis
- cyanotic heart disease: (i.e. R to L shunt) blood bypasses the lungs → no oxygenation occurs → high levels of deoxygenated hemoglobin enters the systemic circulation → cyanosis

![Figure 2. Common congenital heart diseases](image)

Acyanotic Congenital Heart Disease

1. LEFT TO RIGHT SHUNT LESIONS
- extra blood is displaced through a communication from the left to the right side of the heart → increased pulmonary blood flow → increased pulmonary pressures
- shunt volume is dependent upon three factors: (1) size of defect (2) pressure gradient between chambers or vessels (3) peripheral outflow resistance
- untreated shunts can result in pulmonary vascular disease, left ventricular dilatation and dysfunction, right ventricular hypertension and hypertrophy (RVH), and ultimately R to L shunts

Atrial Septal Defect (ASD)
- 3 types: ostium primum (common in Down syndrome), ostium secundum (most common type, 50-70%), sinus venosus (defect located at entry of superior vena cava into right atrium)
- epidemiology: 6-8% of congenital heart lesions
- natural history:
  - 80-100% spontaneous closure rate if ASD diameter <8 mm
  - if remains patent, congestive heart failure (CHF) and pulmonary hypertension can develop in adult life
- clinical presentation:
  - history: often asymptomatic in childhood
  - physical exam: grade 2-3/6 pulmonic outflow murmur, widely split and fixed S2
- investigations:
  - ECG: right axis deviation (RAD), mild RVH, right bundle branch block (RBBB)
  - CXR: increased pulmonary vasculature
- management: elective surgical or catheter closure between 2-5 yr of age

Ventricular Septal Defect (VSD)
- most common congenital heart defect (30-50%)
- small VSD (majority)
  - clinical presentation:
    - history: asymptomatic, normal growth, and development
    - physical exam: early systolic to holosystolic murmur, best heard at LLSB, thrill
  - investigations: ECG and CXR are normal
  - management: most close spontaneously

Characteristic Chest X-Ray Findings in Congenital Heart Disease
- Boot-shaped heart: tetralogy of Fallot, tricuspid atresia
- Egg-shaped heart: transposition of great arteries
- “Snowman” heart: total anomalous pulmonary venous return
• moderate-to-large VSD
  • epidemiology: CHF by 2 mo; late secondary pulmonary hypertension if left untreated
  • clinical presentation
    • history: delayed growth, decreased exercise tolerance, recurrent URTIs or "asthma" episodes
    • physical exam: holosystolic murmur at LLSB, mid-diastolic rumble at apex, size of VSD is inversely related to intensity of murmur
  • investigations:
    • ECG: left ventricular hypertrophy (LVH), left atrial hypertrophy (LAH), RVH
    • CXR: increased pulmonary vasculature, cardiomegaly, CHF
  • management: treatment of CHF and surgical closure by 1 yr old

Patent Ductus Arteriosus (PDA)
• patent vessel between descending aorta and left pulmonary artery (normally, functional closure within first 15 h of life, anatomical closure within first days of life)
• epidemiology:
  • 5-10% of all congenital heart defects
  • delayed closure of ductus is common in premature infants (1/3 of infants <1750 g); this is different from PDA in term infants
• natural history: spontaneous closure common in premature infants, less common in term infants
• clinical presentation
  • history: asymptomatic, or have apneic or bradycardic spells, poor feeding, accessory muscle use, CHF
  • physical exam:
    • tachycardia, bounding pulses, hyperactive precordium, wide pulse pressure, continuous "machinery" murmur best heard at left infraclavicular area
  • investigations:
    • ECG: may show LAE, LVH, RVH
    • CXR: normal to mildly enlarged heart, increased pulmonary vasculature, prominent pulmonary artery
    • ECHO: diagnostic
• management
  • indomethacin (Indocid®): PGE2 antagonist (PGE2 maintains ductus arteriosus patency) is only effective in premature infants
  • catheter or surgical closure if PDA causes respiratory compromise, FTT, or persists beyond 3rd month of life

2. OBSTRUCTIVE LESIONS
• present with decreased urine output, pallor, cool extremities and poor pulses, shock or sudden collapse

Coarctation of the Aorta
• definition: narrowing of aorta (almost always at the level of the ductus arteriosus)
• epidemiology: commonly associated with bicuspid aortic valve (30%); Turner syndrome (35%)
• clinical presentation
  • history: often asymptomatic
  • physical exam:
    • upper extremity systolic pressures of 140-145 mmHg
    • few have high BP in infancy (160-200 mmHg systolic), but this decreases as collaterals develop
    • decreased blood pressure and weak/absent pulses in lower extremities
    • radial-femoral delay
    • absent or systolic murmur with late peak at apex, left axilla, and left back
    • if severe, presents with shock in the neonatal period when the ductus closes
• investigations: ECG shows RVH early in infancy, LVH later in childhood
• prognosis: can be complicated by hypertension; if associated with other lesions (e.g. PDA, VSD) can lead to CHF
• management: give prostaglandins to keep ductus arteriosus patent for stabilization and perform surgical correction in neonates. For older infants and children balloon arterioplasty may be an alternative to surgical correction.

Aortic Stenosis
• 4 types: valvular (75%), subvalvular (20%), supravalvular and idiopathic hypertrophic subaortic stenosis (IHSS) (5%)
• clinical presentation
  • history: often asymptomatic, but may be associated with CHF, exertional chest pain, syncope or sudden death
  • physical exam: systolic ejection murmur (SEM) at RUSB with aortic ejection click at the apex (only for valvar stenosis)
• management: valvular stenosis is usually treated with balloon valvuloplasty, patients with subvalvar or supravalvular stenosis require surgical repair, exercise restriction required
Pulmonary Stenosis
- 3 types: valvular (90%), subvalvular, or supravalvular
- definition of critical pulmonic stenosis:
  - inadequate pulmonary blood flow, dependent on ductus for oxygenation, progressive hypoxia and cyanosis
- natural history: may be part of other congenital heart lesions (e.g. Tetralogy of Fallot) or in association with syndromes (e.g. congenital rubella, Noonan syndrome)
- clinical presentation
  - history: spectrum from asymptomatic to CHF
  - physical exam: wide split S2 on expiration, SEM at LUSB, pulmonary ejection click (for valvar lesions)
- investigations:
  - ECG: RVH
  - CXR: post-stenotic dilation of the main pulmonary artery
- management: surgical repair if critically ill, or if symptomatic in older infants/children

Cyanotic Congenital Heart Disease
- systemic venous return re-enters systemic circulation directly
- most prominent feature is cyanosis (O₂ sat <75%)
- hyperoxic test differentiates between cardiac and other causes of cyanosis
  - obtain preductal, right radial ABG in room air, then repeat after the child inspires 100% O₂
  - if PaO₂ improves to greater than 150 mmHg, cyanosis less likely cardiac in origin

1. RIGHT TO LEFT SHUNT LESIONS
Tetralogy of Fallot
- epidemiology: 10% of all CHD, most common cyanotic heart defect diagnosed beyond infancy with peak incidence at 2-4 mo of age
- pathophysiology:
  - embryological defect due to anterior and superior deviation of the outlet septum leading to:
    - VSD, RVOTO (e.g. pulmonary stenosis), over-riding aorta and RVH
    - infants may initially have a L → R shunt (therefore no cyanosis); however, RVOTO is progressive, leading to increasing R → L shunting with hypoxemia and cyanosis
  - degree of RVOTO determines the direction and degree of shunt and, therefore, the extent of clinical cyanosis and degree of RVH
- clinical presentation
  - history: hypoxic "tet" spells
  - during exertional states (crying, exercise) the increasing pulmonary vascular resistance and decrease in systemic resistance causes an increase in right-to-left shunting
  - clinical features include paroxysm of rapid and deep breathing, irritability and crying, increasing cyanosis, decreased intensity of murmur (decreased flow across RVOTO)
  - if severe, can lead to decreased level of consciousness, seizures, death
  - physical exam
    - single loud S2 due to severe pulmonary stenosis (i.e. RVOTO), systolic ejection murmur (LSB)
- investigations:
  - ECG: RAD, RVH
  - CXR: boot shaped heart, decreased pulmonary vasculature, right aortic arch (in 20%)
- management of spells: O₂, knee-chest position, fluid bolus, morphine sulfate, propanolol
- treatment: surgical repair at 4-6 mo of age; earlier if marked cyanosis or "tet" spells

2. OTHER CYANOTIC CONGENITAL HEART DISEASES
Transposition of the Great Arteries (TGA)
- epidemiology: 3-5% of all congenital cardiac lesions, most common cyanotic CHD in neonate
- pathophysiology: parallel pulmonary and systemic circulations
  - systemic: body → RA → RV → aorta → body
  - pulmonary: lungs → LA → LV → pulmonary artery → lungs
- survival is dependent on mixing through PDA and/or atrial or ventricular septal defects
- physical exam:
  - neonates: ductus arteriosus closure causes rapidly progressive severe hypoxemia unresponsive to oxygen therapy, acidosis, and death
  - VSD present: cyanosis is not prominent; CHF within first weeks of life
  - VSD absent: no murmur
- investigations:
  - ECG: RAD, RVH, or may be normal
  - CXR: egg-shaped heart with narrow mediastinum ("egg on a string")
- management:
  - symptomatic neonates: prostaglandin E1 infusion to keep ductus open until balloon atrial septostomy
  - surgical repair: arterial switch performed in the first two weeks in those without a VSD while LV muscle is still strong

Total Anomalous Pulmonary Venous Connection
- epidemiology: 1-2% of CHD
- pathophysiology:
  - all pulmonary veins drain into right-sided circulation (systemic veins, RA)
  - no direct oxygenated pulmonary venous return to left atrium
  - often associated with obstruction at connection sites
  - ASD must be present for oxygenated blood to shunt into the LA and systemic circulation
- management: surgical repair in all cases and required urgently for severe cyanosis

Truncus Arteriosus
- pathophysiology:
  - single great vessel gives rise to the aorta, pulmonary and coronary arteries
  - truncal valve overlies a large VSD
  - potential for coronary ischemia with fall in pulmonary vascular resistance
- management: surgical repair within first 6 wk of life

Hypoplastic Left Heart Syndrome (HLHS)
- epidemiology: 1-3% of CHD; commonest cause of death from CHD in first month of life
- pathophysiology: LV hypoplasia may include atretic or stenotic mitral and/or aortic valve, small ascending aorta, and coartation of the aorta with resultant systemic hypoperfusion
- systemic circulation is dependent on ductus patency; upon closure of the ductus, infant presents with circulatory shock and metabolic acidosis
- management:
  - intubate and correct metabolic acidosis
  - IV infusion of PGE1 to keep ductus open
  - surgical palliation (overall survival 50% to late childhood) or heart transplant

Congestive Heart Failure (CHF)
- see Cardiology, C30

Etiology
- CHD
- arteriovenous malformations (AVMs)
- cardiomyopathy
- arrhythmias
- acute hypertension
- anemia
- cor pulmonale
- myocarditis

History
- infant: feeding difficulties, early fatigability, diaphoresis while sleeping or eating, respiratory distress, lethargy, FTT
- child: decreased exercise tolerance, fatigue, decreased appetite, failure to thrive, respiratory distress, frequent URTIs or “asthma” episodes
- orthopnea, paroxysmal nocturnal dyspnea, pedal/dependent edema are all uncommon in children

Physical Findings
- 4 key features: tachycardia, tachypnea, cardiomegaly, hepatomegaly
- FTT
- alterations in peripheral pulses, four limb blood pressures (in some CHDs)
- dysmorphic features associated with congenital syndromes

Investigations
- CXR: cardiomegaly, pulmonary venous congestion

Management
- general: sitting up, O2, sodium and water restriction, increased caloric intake
- pharmacologic: diuretics, afterload reduction (i.e. ACE inhibitor), digoxin rarely used
- curative: correction of underlying cause
**Dysrhythmias**

- see [Cardiology, C12](#)
- can be transient or permanent, congenital (structurally normal or abnormal) or acquired (toxin, infection, infarction)

**Sinus Arrhythmia**
- phasic variations with respiration (present in almost all normal children)

**Sinus Tachycardia**
- rate of impulses arising from sinus node is elevated (>150 bpm in infants, >100 bpm in older children)
- etiology: hypertension, fever, anxiety, sepsis, anemia/hypoxia, PE, drugs, etc.
- differentiate from SVT (see below) by slowing the sinus rate (vagal massage, β-blockers) to identify sinus P waves

**Premature Atrial Contractions (PACs)**
- may be normal variant or can be caused by electrolyte disturbances, hyperthyroidism, cardiac surgery, digitalis toxicity

**Premature Ventricular Contractions (PVCs)**
- common in adolescents
- benign if single, uniform, disappear with exercise, and no associated structural lesions
- if not benign, may degenerate into more severe dysrhythmias

**Supraventricular Tachycardia (SVT)**
- abnormally rapid heart rhythm originating above the ventricles – most frequent sustained dysrhythmia in children
- not life-threatening, but can lead to symptoms

**Complete Heart Block**
- congenital heart block can be caused by maternal anti-Ro or anti-La (e.g. mother with SLE)
- often diagnosed in utero (may lead to development of fetal hydrops)
- clinical symptoms related to level of block (the lower the block, the slower the heart rate and greater the symptoms of inadequate cardiac output)
- symptomatic patients need a pacemaker

---

**Heart Murmurs**

- 50-80% of children have audible heart murmurs at some point in their childhood
- most childhood murmurs are functional (e.g. "innocent") without associated structural abnormalities and have normal ECG and radiologic findings
- in general, murmurs can become audible or accentuated in high output states, e.g. fever, anemia

**Table 11. Differentiating Heart Murmurs**

**Pediatric vs. Adult ECG**

Pediatric ECG findings that may be normal:
- HR >100 bpm
- Shorter PR, QT intervals and QRS duration
- Inferior and lateral small Q waves
- RV larger than LV in neonates, so normal to have:
  - Right axis deviation
  - Large precordial R waves
  - Upright T waves
  - Inverted T waves in the anterior precordial leads from early infancy to teen years

**Infective Endocarditis**
- see Infectious Diseases, ID17

**Development**

**Approach to Global Developmental Delay**
- also known as Early Developmental Impairment (EDI)

**Definition**
- performance significantly below average in two or more areas of development (i.e. gross motor, fine motor, language, cognitive, social, adaptive)
- when persistent, these become developmental disabilities which are lifelong impairments

**Epidemiology**
- 5-10% of children have neurodevelopmental delay
- careful evaluation can reveal a cause in 50-70% of cases

**Etiology**
- CNS abnormalities (meningitis/encephalitis, brain malformation, trauma, etc.)
- sensory deficits (hearing, vision)
- environmental (psychosocial neglect, lead exposure, antenatal drug or alcohol exposure, etc.)
- genetic/chromosomal disorders (Down syndrome, Fragile X, etc.)
- metabolic disorders (inborn errors of metabolism, hypothyroidism, etc.)
- obstetrical (prematurity, hypoxic ischemic encephalopathy, TORCH infections, etc.)

**Clinical Presentation**
- history
  - intrauterine exposures, perinatal events
  - detailed developmental milestones: rate of acquisition, regression of skills
  - associated problems: feeding, seizures, behaviour, sleep
  - family history, consanguinity
  - social history
- physical
  - dysmorphic features, hepatosplenomegaly, neurocutaneous markers, growth parameters, detailed neurological examination
- investigations
  - neurodevelopmental assessment, vision and hearing test, psychosocial evaluation, OT, PT and/or SLP assessments, genetics consultation
  - laboratory testing and imaging (guided by history and physical exam)
    - microarray, chromosomes, FISH, Fragile X testing, neuroimaging, metabolic workup, neuroelectrophysiologic testing

**Management**
- dependent on specific area of delay
- therapy services (e.g. speech and language therapy for language delay, OT and/or PT for motor delay), early intervention services (e.g. infant development services, Ontario Early Years Centres)
**Intellectual Disability**

**Definition**
- state of functioning that begins in childhood and is characterized by limitations in both intelligence and adaptive skills
- referred to as mental retardation in DSM-IV, not a term used in clinical settings
- historically defined as an IQ <70

**Epidemiology**
- 1% of general population; M:F = 1.5:1

**Etiology**
- any disorder that interferes with brain development and functioning
- prenatal (majority): TORCH infections, fetal alcohol syndrome
- genetic/metabolic: DS, Fragile X, PKU, untreated or delayed diagnosis of congenital hypothyroidism, CNS abnormalities, other chromosomal/metabolic disorders

**Risk Factors**
- male, consanguineous parents, family history, older maternal age, decreasing maternal education, certain ethnicities
- prenatal: pre-eclampsia, maternal malnutrition or DM
- perinatal: prematurity, low birth weight, birth trauma/hypoxia
- postnatal: intracranial hemorrhage, CNS or other serious infection, hypoxia, environmental toxins, psychosocial deprivation, malnutrition

**Clinical Presentation**
- history
  - well below average general intellectual functioning
  - significant deficits in adaptive functioning in at least two of: communication, self-care, home-living, social skills, self-direction, academic skills, work, leisure, health, safety
- physical
  - check growth, dysmorphic features, complete physical exam
- investigations
  - standardized psychology assessment (includes IQ test and measure of adaptive functioning)
  - vision, hearing, and neurologic assessment
  - genetic and metabolic testing as indicated

**Management**
- main objective: enhance adaptive functioning level
- requires an interprofessional team with strong case co-ordination
- emphasize community-based treatment and early intervention
- individual/family therapy, behaviour management services, therapy services (e.g. OT, SLP), medications for associated conditions
- education: life skills, vocational training, communication skills, family education
- psychosocial support for individual and family; respite care

**Prognosis**
- higher rates of sensory deficits, motor impairment, behavioural/emotional disorders, seizures, psychiatric illness

**Language Delay**

**Definition**
- no universally accepted definition, but often identified around 18 mo of age with enhanced well baby visit
- if formally tested, performance on a standardized assessment of language is at least one standard deviation below mean of age
- can be expressive, receptive, or both
- expressive language: ability to produce or use language
- receptive language: ability to understand language

**Epidemiology**
- ~10-15% of 2 yr old children have a language delay, but only 4-5% remain delayed after 3 yr of age
- ~6-8% of school-aged children have specific language impairment (many of whom were not identified before school entry)
Etiology
- cognitive disability
- constitutional language delay
- genetic/metabolic: DS, Fragile X syndrome, Williams syndrome, hypothyroidism, PKU, etc.
- hearing impairment
- mechanical problems: cleft palate, cranial nerve palsy
- medical condition: seizure disorder (includes acquired epileptic aphasia), CP, TORCH infection, iron deficiency, lead poisoning, etc.
- autism spectrum disorder (ASD)
- psychosocial: neglect or abuse
- selective mutism

Risk Factors
- male, positive family history, prematurity, psychosocial (poverty, low parental education, maternal depression)

Clinical Presentation
- history
  - concerns about hearing, delay in language development or regression in previously normal language development
  - delayed language milestones on well-child check up; presence of red flags
  - must determine if language delay is expressive, receptive or mixed
  - children with expressive language delays may have concurrent behaviour problems or drooling (because of abnormal oral musculature)
  - risk factors for hearing loss (hereditary, recurrent AOM) and language delay
- physical
  - guided by history: look for abnormal growth, dysmorphisms, unusual social interactions (lack of eye contact, not pointing)
  - include full exam of the external/internal ear (e.g. TM scarring), oral pharynx (e.g. cleft palate) and neurologic system (including tone)
- investigations
  - use of language specific screens in primary care setting: The Early Language Milestone, CAT/CLAMS, MCHAT, etc.
  - all children with suspected language delay MUST be referred to an audiologist for a hearing assessment
  - CBC (to rule out anemia), venous blood lead levels, genetic/metabolic workup as indicated

Management
- specific to etiology
- often multidisciplinary and requires appropriate referrals: early intervention services, special education services, SLP, ENT and dental professionals, general support services
- primary care provider can help reinforce family’s understanding of delay and provide follow-up and care coordination
- prevention: parents can read aloud to their child, engage in dialogic reading, avoid baby talk, narrate daily activities, etc.

Prognosis
- depends on etiology
- if language delay persists beyond 5 yr old then more likely to have difficulties in adulthood
- persistent language delay is associated with poor academic performance, behavioural problems, social isolation

Fetal Alcohol Spectrum Disorder (FASD)

Definition
- term describing the range of effects of prenatal exposure to alcohol, including physical, mental, behavioural and learning disabilities
- no “safe” level of alcohol consumption during pregnancy has been established
- spectrum includes: Fetal Alcohol Syndrome (FAS), partial Fetal Alcohol Syndrome (pFAS), Alcohol-Related Birth Defects (ARBD), and Alcohol-Related Neurodevelopmental Disorder (ARND)

Epidemiology
- prevalence of FAS and FASD is 0.1% and 1.0%, respectively
- most common preventable cause of intellectual disability

Pathogenesis
- specific mechanism of FASD is unknown, but hypothesis include nutritional deficits, toxic effects of acetaldehyde, alteration of placental transport, abnormal protein synthesis, and altered cerebral neurotransmitter
Diagnosis
- often misdiagnosed or missed entirely
- diagnosis of FAS, ARBD and ARND all require evidence of maternal drinking during pregnancy
- criteria for diagnosis of FAS
  a) growth deficiency: low birth weight and/or decelerating weight over time not due to nutrition
  b) characteristic pattern of facial anomalies: short palpebral fissures, flattened philtrum, thin upper lip, flat midface
  c) central nervous system dysfunction: microcephaly and/or neurobehavioral dysfunction (hyperactivity, fine motor problems, attention deficits, learning disabilities, cognitive disabilities, difficulties in adaptive functioning, etc.)
- criteria for diagnosis of ARBD
  a) congenital anomalies, including malformations and dysplasias of the cardiac, skeletal, renal, ocular, and auditory systems
- criteria for diagnosis of ARND
  a) central nervous system dysfunction (similar to FAS)
  b) complex pattern of behavioral or cognitive abnormalities inconsistent with developmental level that cannot be explained by familial background or environment alone

Management
- early diagnosis is essential to prevent secondary disabilities
- no cure, but individuals with FASD and their families should be linked to community resources and services to improve outcome

Prognosis
- secondary disabilities include unemployment, mental health problems, difficulties with the law, inappropriate sexual behaviour, disrupted school experience, peer problems

Learning Disabilities

Definition
- specific and persistent failure to acquire academic skills despite conventional instruction, adequate intelligence, and sociocultural opportunity
- a significant discrepancy between a child's intellectual ability and their academic performance
- several types or ADLs: learning disabilities in reading, writing, mathematics

Epidemiology
- prevalence: 2-10%
- high incidence of psychiatric comorbidity: anxiety, dysthymia, conduct disorder (CD), major depressive disorder (MDD), oppositional defiant disorder (ODD), attention deficit hyperactivity disorder (ADHD)

Etiology
- pathogenesis is unknown, likely genetic factors involved
- learning disabilities may be associated with a number of conditions:
  - genetic/metabolic: Turner syndrome, Klinefelter syndrome
  - perinatal: prematurity, low birth weight, birth trauma/hypoxia
  - postnatal: CNS damage, hypoxia, environmental toxins, FAS, psychosocial deprivation (understimulation), malnutrition
- poor visual acuity is NOT a cause

Risk Factors
- positive family history, prematurity, other developmental and mental health conditions, neurologic disorders (e.g. seizure disorders, neurofibromatosis), history of CNS infection/irradiation/traumatic injury

Clinical Presentation
- history and physical
  - school difficulties (academic achievement, behaviour, attention, social interaction)
  - development of negative self-concept → reluctance to participate even in areas of strength
  - social issues: overt hostility towards parents/teachers; difficulties making friends for several reasons (problems remembering names, difficulties with language to engage in conversations, inability to understand games and complex rules, etc.), bullying and anxiety
- look for dysmorphisms, complete physical exam
- investigations
  - standardized tests for IQ
  - individual scores on achievement tests in reading, mathematics or written expression (WISC III, WRAT) >2 SD below that expected for age, education, and IQ
Management
• provide quality instruction for specific learning disability
• support student by modifying the curriculum and/or providing accommodations (e.g. scribe for writing, extra time for tests, photocopied notes, etc.)
• consider grade retention in certain students (no guidelines exist, very rare in Ontario)
• specialized education placements that can provide educational remediation

Prognosis
• limited information available about persistence of learning disabilities over time
• low self-esteem, poor social skills, 40% school drop-out rate

Motor Delay
• see Cerebral Palsy, P90 and Muscular Dystrophy, P44

Endocrinology

Anti-Diuretic Hormone

Diabetes Insipidus (DI)
• see Endocrinology, E19 and Nephrology, NP11

Syndrome of Inappropriate Antidiuretic Hormone (SIADH)
• see Endocrinology, E19 and Nephrology, NP9

Diabetes Mellitus (DM)

DM Type 1
• insulin deficiency following destruction of the pancreatic β cells

Epidemiology
• most common form of diabetes mellitus in children, M=F
• variable prevalence internationally, affects ~1:4000 children in Canada
• can present at any age, but bimodal peaks at 5-7 yr old and at puberty

Etiology
• type 1A: cell-mediated autoimmune destruction of β-cells of the pancreas
• type 1B: rare, non-immune variation; unknown cause
• disease results from some level of genetic predisposition and an environmental trigger
  ▪ HLA locus confers ~50% of genetic susceptibility
  ▪ trigger likely infectious and/or hormonal (as suggested by bimodal peaks in age of onset)

Risk Factors
• positive family history of DM1, personal or family history of other autoimmune diseases

Clinical Presentation
• history
  ▪ initially presents as polyuria, often manifested as nocturia or secondary enuresis
  ▪ polydipsia, weight loss (lack of insulin leading to a catabolic state) and polyphagia
  ▪ diabetic ketoacidosis on initial presentation (~20%): vomiting, abdominal pain, confusion/lethargy
• physical
  ▪ tachypnea, signs of dehydration, ↓ LOC, Kussmaul’s respiration, ketone breath
• investigations
  ▪ initial tests: urine dipstick (glucose, ketones), random blood glucose (>11.1)
  ▪ DKA bloodwork: venous/arterial blood gas, osmolarity, plasma glucose, bicarbonate, HbA1C, serum ketones, BUN, Cr, electrolytes, CBC
  ▪ if etiology is unclear, consider ordering autoimmune antibodies (anti-Gad, anti-islet)

Management
• disclose diagnosis and prompt patient education around survival skills, meal plans and insulin injections
• refer patient to facility capable of managing DM1
• management is multi-disciplinary and family-centered
• initial insulin dosing
  ▪ 2/3 of total daily insulin dose in AM (1/3 rapid acting + 2/3 intermediate-acting)
  ▪ 1/3 of total daily insulin dose in PM (1/3 rapid acting + 2/3 intermediate-acting)

Diagnostic Criteria for Diabetes Mellitus (Types 1 and 2)
One of:
• HbA1C 6.5% (not validated in children)
• Fasting glucose ≥7.0 mmol/L
• 2 h plasma glucose during OGTT ≥11.1 mmol/L
• Random glucose ≥11.1 mmol/L with classic symptoms of hyperglycemia (polyuria, polydipsia, weight loss)

Blood Glucose Targets by Age

<table>
<thead>
<tr>

<td>6-12</td>
<td>&lt;8.5%</td>
</tr>
<tr>
<td>6-12</td>
<td>6-10</td>
<td>&lt;8%</td>
</tr>
<tr>
<td>&gt;12</td>
<td>4-7</td>
<td>&lt;7%</td>
</tr>
</tbody>
</table>
• blood glucose monitoring
  ▪ tight glycemic control decreases rate of long term complications
  ▪ target glucose range: in infants/toddlers from 6-10 mmol/L, in children 4-10 mmol/L, in adolescents 4-7 mmol/L
  ▪ for tighter control, may consider continuous subcutaneous insulin infusion (CSII) pump or MDI (multiple daily injections regimen: basal insulin plus analog for meals)
  ▪ young children are more susceptible to hypoglycemia

• if DKA present: ABCs, admit, correct dehydration, correct acidosis (start insulin infusion), restore normal blood glucose, identify/treat precipitating event
  ▪ low threshold to investigate (CT/MRI) and treat DKA, as cerebral edema is a major concern

• screen for micro- and macrovascular complications (regular ophthalmology assessments, blood pressure, urine microalbuminemia), concurrent autoimmune diseases (thyroiditis, celiac disease, etc.) and mental health issues (depression, eating disorders)

Prognosis
• no cure currently
• short-term complications
  ▪ hypoglycemia: due to missed/delayed meals, excess insulin or exercise, illness; can lead to seizures and/or coma; reversed with PO/IV glucose or IM glucagon
  ▪ hyperglycemia: due to intercurrent illness, diet-to-insulin mismatch, ↑ risk of end-organ damage
  ▪ DKA: due to missed insulin doses, infection; most common cause of death
• long-term complications
  ▪ microvascular: retinopathy, nephropathy, neuropathy
  ▪ macrovascular: metabolic syndrome
  ▪ increased risk of other autoimmune diseases

DM Type 2
• see Family Medicine, FM22, Endocrinology, E6
• impaired glucose metabolism due to increased peripheral insulin resistance
• rare before 10 yr of age, but more common in older children/adolescents
• prevalence is rising mainly due to the increased incidence of childhood obesity
• risk factors: obesity, positive family history, female gender, certain ethnic groups
• clinical presentation may be similar to that of DM1, though most children are asymptomatic
• may present in DKA or hyperglycemic hyperosmotic nonketotic (HONK) state
• management: diet, physical activity (60 min of moderate to intense exercise per day, limit non-academic screen time to 2 h/d), weight loss, oral hypoglycemics (metformin used in children because it does not cause hypoglycemia), insulin
• prognosis: includes microvascular and macrovascular complications similar to DM1

Growth

APPROACH TO SHORT STATURE

Definition
• short stature – height <3rd percentile
• poor growth evidenced by growth deceleration (height crosses major percentile lines, growth velocity <25th percentile)

Epidemiology
• ~2.5% of the population by definition

Etiology
• see sidebar

Clinical Presentation
• history and physical
  ▪ plot on growth curve (special growth charts available for Turner syndrome, achondroplasia, DS)
  ▪ decreased growth velocity may be more worrisome than actual height
  ▪ see Figure 7 for the approach to short stature
• investigations
  ▪ calculate mid-parental height: children are usually in a percentile between their parents’ height (see Mid-Parental Height sidebar, P10)
  ▪ AP x-ray of left hand and wrist for bone age
  ▪ remaining investigations guided by history and physical (e.g. TSH, sweat chloride, etc.)
**Management**
- depends on severity of problem as perceived by parents/child
- no treatment for non-pathological short stature, except for idiopathic short stature
- GH therapy if requirements met (see *Growth Hormone Deficiency*, below)
- other conditions that are treated: Turner, Prader-Willi, chronic renal failure
- support and management of resultant self-image issues, social anxiety, etc.

**GROWTH HORMONE (GH) DEFICIENCY**
- a rare but treatable cause of short stature in children

**Epidemiology**
- 1/10,000-1/4,000 children

**Etiology**
- GH important for chondrocyte proliferation and IGF-1 release → IGF-1 acts at long bones, liver
- congenital GH deficiency: idiopathic, embryologic CNS malformation (associated with midline facial anomalies, neurologic defects, micropenis in males, hypoglycemia), perinatal asphyxia, rare mutations
- acquired GH deficiency: tumours (e.g. craniopharyngioma), trauma, cranial infection, irradiation, post-surgical

**Risk Factors**
- previous head trauma, history of intracranial bleed or infection, head surgery or irradiation, positive family history, breech delivery

**Clinical Presentation**
- history and physical
  - congenital: growth may be normal in first 6 mo (insulin main growth factor), growth deceleration after; look for microgeni
  - acquired: severe growth failure, ↑ weight/height ratio (short and chubby), infantile fat distribution, immature face with underdeveloped nasal bridge and frontal bossing, high-pitched voice, sparse and thin hair growth, delayed puberty
  - hypothalamic: pituitary dysfunction (micropenis, cryptorchidism, optic nerve hypoplasia, etc.)
  - investigations
    - blood glucose (hypoglycemia), AP x-ray of left hand and wrist for bone age (delayed), IGF-1
    - testing for GH deficiency (stimulation testing), only performed when
      - height <3rd percentile
      - decreased growth velocity
      - midline craniofacial anomalies
      - episodes of hypoglycemia
      - delayed bone age, puberty

---

**Figure 7. Approach to the child with short stature**

- IUGR
  - Primordial
    - Ht, Wt, and HC are affected
    - Chromosomal (e.g. Turner, Dawn)
    - Teratogen, placental insufficiency, infection
  - Proportionate
  - Disproportionate
    - Skeletal dysplasia
  - Normal Growth Velocity
  - Constitutional Growth Delay
    - Delayed puberty
    - May have family history of delayed puberty
    - May need short-term therapy with androgens/estrogens
    - Delayed bone age
    - Often mid-parental height is normal
  - Familial
    - Normal bone age
    - Treatment not indicated
    - Family Hx of short stature
  - Slow Growth Velocity
  - Endocrine (height affected more than weight)
    - GH deficiency
    - Hypothyroidism/Hyperthyroidism
    - Hypercortisolism
    - Hyperpituitarism
    - Adrenal insufficiency
  - Chronic disease (weight affected more than height)
    - Cyanotic congenital heart disease
    - Celiac disease, inflammatory bowel disease, CF
    - Chronic infections
    - Chronic renal failure (often height more affected)
  - Psychosocial neglect (psychosocial dwarfism)
    - Usually decreased height and weight (decreased head circumference if severe)
physiologic increase in GH with arginine, clonidine, insulin, dopamine, or propranolol
positive test if failure to raise GH >5.7 ng/mL post-stimulation

Management
• GH therapy indicated if
  • GH shown to be deficient by 2 different stimulation tests
  • growth velocity <3rd percentile or height <<3rd percentile
  • bone age x-rays show unfused epiphyses/delayed bone age
  • Turner syndrome, Noonan syndrome, Prader-Willi syndrome, chronic renal failure, idiopathic short stature
• support and management of resultant self-image issues, social anxiety, etc.

Prognosis
• if administered at an early age, GH therapy can help patients achieve adult height
• children treated with recombinant GH are at a slightly increased risk of developing pseudotumor cerebri, slipped capital femoral epiphysis and worsening scoliosis
• rare side effects: pancreatitis, transient gynecomastia, increase of growth/pigmentation of nevi

TALL STATURE
• height greater than two SD above the mean for a given age, sex and race

Etiology
• constitutional/familial
• endocrine: Beckwith-Wiedemann syndrome, hyperthyroidism, hypophyseal gigantism, precocious puberty
• genetic: homocystinuria, Klinefelter syndrome, Marfan syndrome, Sotos syndrome

Hypercalcemia/Hypocalcemia/Rickets
• see Endocrinology, E39, E40, E45

Hyperthyroidism and Hypothyroidism
• may be congenital or acquired (for acquired causes, see Endocrinology, E22 and 27)

CONGENITAL HYPERTHYROIDISM
• also known as neonatal Graves’ disease

Epidemiology
• ~1:25,000 neonates, M=F

Etiology
• results from transplacental passage of maternal thyroid stimulating antibodies from mother with a history of Graves’ disease

Clinical Presentation
• history and physical
  • clinical manifestations may be masked if mother on antithyroid treatment
  • may present with tachycardia with congestive heart failure, heart murmur, goiter, craniosynostosis, irritability, poor feeding, FTT
• investigations
  • serum levels of TSH and free T4 in all infants with suspected congenital hypothyroidism or infants born to mothers with Graves’ disease

Management
• methimazole until antibodies cleared
• symptomatic treatment as needed (e.g. β-blockers to control tachycardia)

Prognosis
• if prompt and adequate treatment given, most neonates improve rapidly
• antibodies usually spontaneous cleared by 2-3 mo of life
• fetal or neonatal hyperthyroidism may have adverse effects on CNS development, leading to developmental and behavioural problems
CONGENITAL HYPOTHYROIDISM

**Epidemiology**
- incidence: 1:4000-1:2000 newborns; F:M=2:1
- one of the most common preventable causes of intellectual disability

**Etiology**
- may be classified as permanent primary, central and transient hypothyroidism
- ~85% of primary cases are sporadic (mostly thyroid dysgenesis), remaining 15% hereditary (mostly inborn errors of thyroid synthesis)
- causes of transient hypothyroidism: maternal antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications

**Clinical Presentation**
- history and physical
  - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
  - may have: prolonged jaundice, constipation, sluggish, hoarse cry, lethargy, poor feeding, macroglossia, coarse facial features, large fontanelles, umbilical hernia
- investigations
  - diagnosis through newborn screening of TSH or free T4; abnormal results should be confirmed with serum levels from venipuncture

**Management**
- thyroxine replacement

**Prognosis**
- excellent outcome if treatment started within 1-2 mo of birth
- if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound)

## Sexual Development

AMBIGUOUS GENITALIA

**Definition**
- newborn or child whose gender is difficult to assign based on the appearance of genitalia
- subtype of disorders of sex differentiation (DSD): a condition in which development of chromosomal, gonadal or anatomic sex is atypical
- subtypes: 46,XX DSD, 46,XY DSD, ovotesticular DSD (true hermaphrodite)

**Epidemiology**
- incidence of genital abnormalities at birth is as high as 1:300
- prevalence of complex anomalies with true sexual ambiguity much lower at ~1:5000

**Etiology**
- 46,XY DSD
  - inborn error of testosterone biosynthesis or Leydig cell hypoplasia
  - 5-a-reductase deficiency, androgen receptor deficiency or insensitivity
  - luteinizing hormone (LH)/hCG unresponsiveness
- 46,XX DSD
  - virilizing congenital adrenal hyperplasia (CAH) (most common)
  - maternal source: virilizing ovarian or adrenal tumours, untreated maternal CAH, placental aromatase deficiency
  - ovotesticular DSD
    - both ovarian follicles and seminiferous tubules in the same patient with a 46,XX karyotype
    - mixed gonadal dysgenesis

**Risk Factors**
- parental consanguinity, positive family history of ambiguous genitalia, early childhood illness/death or primary amenorrhea, maternal medications during pregnancy (androgens-progestogens, danazol, phenytoin, aminoglutethimide, endocrine disruptors)

**Clinical Presentation**
- history
  - thorough obstetrical history, including prenatal screens and maternal medications
  - family history: autosomal recessive pattern may suggest CAH, X-linked recessive pattern may suggest androgen insensitivity syndrome
• physical
  • male pseudohermaphrodite (XY): small phallus, hypospadias, undescended testicles
  • female pseudohermaphrodite (XX): clitoral hypertrophy, labioscrotal fusion
  • look for concurrent midline defects, dysmorphic features and congenital abnormalities
• investigations
  • karyotype and genetic work-up as indicated
  • blood work: electrolytes and renin (evidence of salt-wasting in CAH); 17-OH-progesterone, androgens, FSH and LH
  • imaging: abdominal U/S to look for uterus, testicles, ovaries

Management
• depends on underlying etiology
• avoid announcement of probable sex or use of personal pronouns until all tests are complete
• continuous psychosocial support for parents and child during development
• elective surgical reconstruction of genitalia is sometimes possible

CONGENITAL ADRENAL HYPERPLASIA (CAH)

Definition
• autosomal recessive disorder characterized by the partial or total defect of various synthetic enzymes of the adrenal cortex required for cortisol and aldosterone production

Epidemiology
• occurs in ~1:15,000 live births
• most common cause of ambiguous genitalia

Etiology
• for biosynthetic pathways of adrenal cortex, see Endocrinology, E29
• 21-hydroxylase deficiency (21-OH) responsible for ~95% of CAH cases
• results in ↓ cortisol and aldosterone production with shunting toward ↑ androgens
• cortisol deficiency leads to elevated ACTH, which causes adrenal hyperplasia
• rarer causes include deficiencies in 11-OH, cholesterol desmolase, 17-OH and 3-HSD

Clinical Presentation
• depends on which enzyme in cortisol synthesis pathway is defective
• presentation of 21-OH deficiency can be divided into:
  • classic deficiency with salt wasting: inadequate aldosterone resulting in FTT, hyperkalemia, hyponatremia, hypoglycemia, acidosis
  • classic deficiency without salt wasting: simple virilizing type
  • non-classic: signs/symptoms of androgen excess (amenorrhea, precocious puberty, etc.)
• 21-OH deficiency screening is part of many newborn screening programs across North America
• high serum levels of 17-OH progesterone in random blood sample diagnostic for 21-OH deficiency

Management
• correct any abnormalities in fluids, electrolytes or serum glucose
• provide glucocorticoids/mineralcorticoids as necessary, extra glucocorticoids in times of stress
• psychosocial support

Prognosis
• complications if untreated include virilization, acne, salt wasting, hypotension

NORMAL PUBERTAL DEVELOPMENT

Physiology
• puberty occurs with the maturation of the hypothalamic–pituitary–gonadal (HPG) axis
• ↑ pulsatile release of GnRH → ↑ release of LH and FSH → maturation of gonads, release of sex steroids → secondary sexual characteristics
• adrenal production of androgens also required

Females
• onset: age 8-13 yr old (may start as early as 7 yr in girls of African descent)
• usual sequence (Figure 8)
  1. thelarche: breast budding
  2. pubarche: axillary hair, body odour, mild acne
  3. growth spurt
  4. menarche: mean age 12.5 yr; indicates that growth spurt is almost complete; menses may be irregular in duration and length of cycle
• early puberty is common and often constitutional, late puberty is rare (rule out organic causes)
Males
- onset: age 9-14 yr old
- usual sequence
  1. testicular enlargement
  2. penile enlargement
  3. pubarche: axillary and facial hair, body odour, mild acne
  4. growth spurt: occurs later in boys
- early puberty is uncommon (rule out organic causes), late puberty is common and often constitutional
- gynecomastia (transient development of breast tissue) is a common self-limited condition seen in 50% of male during puberty (but any discharge from nipple or fixed mass should be investigated)

Tanner Staging
- scale used in paediatrics that defines physical measurements of development based on external primary and secondary sex characteristics

**Figure 8. Tanner staging**

**PREOCIOUS PUBERTY**

**Definition**
- development of secondary sexual characteristics 2-2.5 SD before population mean
- < 8 yr old for females, < 9 yr old for males

**Epidemiology**
- 1/10,000, F>M

**Etiology**
- usually idiopathic in females (90%), more suggestive of pathology in males (50%)
- central (GnRH dependent)
  - hypergonadotrophic hypergonadism; hormone levels as in normal puberty
  - premature activation of the HPG axis
  - differential diagnosis: idiopathic or constitutional (most common), CNS disturbances (tumours, hamartomas, post-meningitis, increased ICP, radiotherapy), neurofibromatosis (NF), primary severe hypothyroidism
- peripheral (GnRH independent)
  - hypogonadotrophic hypergonadism
  - differential diagnosis: adrenal disorders (CAH, adrenal neoplasm), testicular/ovarian tumour, gonadotropin/bCG secreting tumour (hepatoblastoma, intracranial teratoma, germinoma), exogenous steroid administration, McCune-Albright syndrome, aromatase excess syndrome, rarely hypothyroidism (Van-Wyk-Grumbach syndrome)
Clinical Presentation
- history
  - symptoms of puberty, family history of precocious puberty, medical illness
- physical
  - growth velocity: prepubertal: 4 to 6 cm/yr, growth spurt: boys 8-10 cm/yr, girls 6-8 cm/yr
  - complete physical exam, including Tanner staging and neurological assessment
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, DHEA-S, 17-OH progesterone)
  - secondary tests: MRI head, pelvic U/S, β-hCG, GnRH and/or ACTH stimulation test

Management
- indications for medical intervention to delay progression of puberty: rapid advancement of puberty, early age, risk of compromise of final adult height, psychological
- central causes: goals are to preserve height and alleviate psychosocial stress; GnRH agonists (e.g. leuprolide) most effective
- peripheral causes: goal is to limit effects of elevated sex steroids; treat underlying cause; medications that decrease the production of a specific sex steroid or blocks its effects (e.g. ketoconazole, spiranloactone, tamoxifen, anastrozole), surgical intervention

DELAYED PUBERTY

Definition
- failure to develop secondary sex characteristics by 2-2.5 SD beyond the population mean
  - for males: lack of testicular enlargement by 14 yr old
  - for females: lack of breast development by 13 yr old OR absence of menarche by 16 yr old or within 5 yr of pubertal onset

Epidemiology
- M>F

Etiology
- usually constitutional delay in males, more suggestive of pathology in females
- central causes
  - constitutional delay in activation of hypothalamic-pituitary-gonadal axis (most common)
  - hypogonadotropic hypogonadism
- peripheral causes
  - hypergonadotropic hypogonadism (e.g. primary gonadal failure, gonadal damage, Turner syndrome, hormone deficiency, androgen insensitivity syndrome, etc.)

Clinical Presentation
- history
  - weight loss, short stature, family history of puberty onset, medical illness, high performance athletes (females)
- physical
  - growth velocity (minimum 4 cm/yr), Tanner staging, neurological exam, complete physical exam
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, IGF-1), CBC, electrolytes, BUN, Cr, liver function tests, liver enzymes, ESR, CRP, urinalysis
  - secondary tests: MRI head, pelvic U/S, karyotype, IBD panel, celiac disease panel, LH levels following GnRH agonist

Management
- identify and treat underlying cause
- hormonal replacement: cyclic estradiol and progesterone for females, testosterone for males
**Vomiting**

**History**
- characteristic of emesis (e.g. projectile, bilious, bloody)
- pattern of emesis (e.g. association with feeds, cyclic, morning)
- associated symptoms (e.g. anorexia, diarrhea, etc.)
- red flags: bilious or bloody emesis, projectile vomit, abdominal distension and tenderness, high fever, signs of dehydration

**Physical Findings**
- vital signs to determine clinical status and hydration state
- dictated by suspected differential (see Table 13)

**Investigations**
- CBC, electrolytes, BUN, Cr, amylase, lipase done routinely
- in sick child, add: ESR, venous blood gases, culture and sensitivity (blood, stool), imaging
- dictated by suspected differential (see Table 13)

| Table 13. Common Differential Diagnosis, Associated Findings and Diagnostic Approach Based on Age |
|-----------------|-----------------|-----------------|
| **Cause**       | **Suggestive Findings** | **Diagnostic Approach** |
| **NEONATES – NON-BILIOUS** | | |
| Tracheoesophageal fistula | Vomiting, excessive secretions soon after birth (e.g. drooling, choking, respiratory distress), inability to feed, inability to advance through NG tube | Inability to advance NG tube, CXR, upper GI series with water-soluble contrast |
| Pyloric stenosis | Projectile vomiting immediately after feeding, dehydrated, palpable "olive" in RUQ, decreased stools, hunger | U/S of pylorus, upper GI study Electrolytes, blood gas (hypokalemic, hypochloremic metabolic alkalosis) |
| GERD | Fussiness after feeds, spit ups, arching of back, poor weight gain | Empiric trial of acid suppression, pH monitoring study, UGI, endoscopy |
| Sepsis | Fever, lethargy, tachycardia, tachypnea, widening pulse pressure | CBC, cultures (blood, urine, CSF), CXR |
| Inborn error of metabolism | Poor feeding, failure to thrive, jaundice, hepatosplenomegaly, cardiomyopathy, dysmorphia, developmental delay | Electrolytes, blood gas (hyponatremic, hyperkalemic metabolic acidosis), lactate, ammonia, LFTs, BUN, Cr, serum Glu, bilirubin, PT/PTT, CBC |
| **NEONATES – BILIOUS** | | |
| Duodenal atresia | Bilious vomiting, abdominal distension, often seen in Down’s syndrome, jaundice, polyhydramnios during pregnancy | AXR, upper GI series (‘double bubble’ sign) |
| Malrotation with volvulus | Bilious emesis, abdominal distension, pain, bloody stool, shock | AXR, upper GI series, contrast enema |
| Hirschsprung’s disease | Bilious emesis, abdominal distension, pain, failure to pass stool | AXR, upper GI series, contrast enema, rectal biopsy |
| **CHILDREN AND ADOLESCENTS** | | |
| Gastroenteritis | Diarrhea, fever, sick contact, recent travel | CBC, stool culture |
| Appendicitis | Periumbilical discomfort that later localizes to RLQ, fever, anorexia | Abdominal U/S |
| Intussusception | Colicky progressive abdominal pain, drawing of leg up to chest, lethargy, bloody stool | Abdominal U/S |
| Non-GI infection (e.g. meningitis) | Fever, localized findings depending on cause | Cultures (CSF, blood, urine), brain imaging |
| Increased intracranial pressure | Nocturnal wakening, progressive recurrent headache worse with Valsalva, nuchal rigidity | Brain CT without contrast Therapeutic LP in idiopathic intracranial hypertension |
| Toxic ingestion | Finding possibly varying by substance- toxidrome, often a history of ingestion | Qualitative and sometimes quantitative levels (urine, blood) |
| Pregnancy | Amenorrhea, morning sickness, bloating, breast tenderness | Urine β-HCG |
| Cyclic vomiting | At least 3 self-limited episodes of vomiting lasting 12 h, 7 d between episodes, no organic cause of vomiting | Diagnosis of exclusion |
Management
- rehydration (see Nephrology, P79)
- treat underlying cause (see detailed differential diagnosis above)

**Gastroesophageal Reflux**

**Epidemiology**
- extremely common in infancy (up to 50%)

**Clinical Presentation**
- vomiting typically soon after feeding, non-bilious, rarely contains blood, small volume (<30 mL)

**Investigations**
- thriving baby requires no investigation
- investigations required if concomitant FTT, feeding aversion, recurrent cough, pneumonia or bronchospasm, GI blood loss or symptoms persist after 18 mo

**Management**
- conservative: thickened feeds, frequent and smaller feeds
- medical:
  - short-term parenteral (NG) feeding to enhance weight gain
  - ranitidine, omeprazole: decreases gastric acidity, decreases esophageal irritation
  - domperidone, metoclopramide: improves gastric emptying and GI motility
- surgical: indicated for failure of medical therapy (Nissen fundoplication)

**Complications**
- esophagitis, strictures, Barrett's esophagus, FTT, aspiration, oral feeding aversion

**Tracheoesophageal Fistula (TEF)**
- see General Surgery, GS64

**Pyloric Stenosis**
- see General Surgery, GS61

**Duodenal Atresia**
- see General Surgery, GS63

**Malrotation of the Intestine**
- see General Surgery, GS62

**Diarrhea**
- definition of diarrhea varies with diet and age (stool normalcy difficult to define in children)
  - infants → increase in stool frequency to twice as often per day; older children → 3+ loose or watery stools/d
  - duration: acute: <2 wk; chronic: >2 wk

**Pathophysiology**
- osmotic: due to non-absorbable solutes in GI tract (e.g. lactose intolerance)
- secretory: increased secretion of Cl- ions and water in intestinal lumen (e.g. bacterial toxin)
- malabsorption: decreased GI surface area (e.g. short bowel syndrome)

**History**
- frequency, duration, quality of diarrhea
- associated symptoms (e.g. fever, abdominal pain, hematochezia, etc.)
- recent antibiotic use or recent travel
- elements of diet

**Physical Findings**
- vital signs to determine clinical status and hydration state
- dictated by suspected differential (see Tables 14 and 15, P36)

Diarrhea is defined as an increase in frequency and/or decreased consistency of stools compared to normal.

Normal stool volume:
Infants: 5-10 g/kg
Children: 200 g/d

Diarrhea Red Flags
- Bloody stool, fever, petechiae or purpura, signs of severe dehydration, weight loss/FTT.
Investigations

- **Acute diarrhea:**
  - stool for culture and sensitivity, ova and parasites, electron microscopy for viruses, *C. difficile* toxin, microscopy (leukocytes suggestive of invading pathogen), blood and urine cultures, bloodwork

- **Chronic diarrhea:**
  - serial heights, weights, growth percentiles
  - if child growing well and thriving, workup is limited (stool cultures as above, stool reducing substances)
  - red flags: poor growth, chronic rash, other serious infections, hospitalizations for dehydration
    - require full work-up (as per below)
  - stool: consistency, pH, reducing substances, microscopy, occult blood, O&P, C&S, *C. difficile* toxin, 3 d fecal fat, α-1 antitrypsin clearance, fecal elastase
  - urinalysis, urine culture
  - CBC, differential, ESR/CRP, smear, electrolytes, total protein, albumin, Ca²⁺, PO₄³⁻, Mg²⁺, Fe, ferritin, folate, fat-soluble vitamins, PTT, INR

- sweat chlorides, celiac screen, thyroid function tests, urine vanillyl mandellic acid (VMA) and homovanillic acid (HVA), HIV test, lead levels

- CXR, upper GI series and follow-through

- specialized tests: endoscopy, small bowel biopsy

**Differential Diagnosis**

**Infective Diarrhea**

<table>
<thead>
<tr>
<th>Viral Infection</th>
<th>Bacterial Infection</th>
</tr>
</thead>
</table>
| **Etiology**   | Most common cause of gastroenteritis
Commonly: rotaviruses, astroviruses, Norwalk virus (typically older children) |

| **Presentation Clinical** | | |
|---------------------------|-------------------|
| Associated with URIs      | Severe abdominal pain |
| Resolves in 3-7 d         | High fever |
| Slight fever, malaise, vomiting, vague abdominal pain | Bloody diarrhea |

| **Risk Factors** | |
|------------------| |
| Day care         | Travel |
| Poorly cooked meat | Poorly refrigerated foods |
| Prolonged antibiotics |

| **Management** | |
|----------------| |
| Prevention and treatment of dehydration most important (see Dehydration, P79) | |
| Early refueling advisable, start with small amounts of easily digested carbohydrates, postpone dairy and fibrous vegetables | |
| Antibiotic therapy when indicated, antidiarrheal medications not indicated | |
| Notify Public Health authorities if appropriate | |
**Toddler’s Diarrhea**

**Epidemiology**
- most common cause of chronic diarrhea during infancy
- onset between 6-36 mo of age, ceases spontaneously between 2-4 yr

**Clinical Presentation**
- diagnosis of exclusion in thriving child
- 4-6 bowel movements per day
- diet history (e.g. excess juice intake overwhelms small bowel resulting in disaccharide malabsorption)
- stool may contain undigested food particles
- excoriated diaper rash

**Management**
- reassurance that it is self-limiting
- 4Fs (adequate Fibre, normal Fluid intake, 35-40% Fat, discourage excess Fruit juice)

**Lactase Deficiency (Lactose Intolerance)**

**Clinical Presentation**
- chronic, watery diarrhea and abdominal pain, bloating associated with dairy intake
- primary lactose intolerance: crampy abdominal pain with loose stool (older children, usually of East Asian and African descent)
- secondary lactose intolerance: older infant, persistent diarrhea (post viral/bacterial infection, Celiac disease, or IBD)

**Diagnosis**
- trial of lactose-free diet
- watery stool, acid pH, positive reducing sugars
- positive breath hydrogen test if >6 yr

**Management**
- lactose-free diet, soy formula
- lactase-containing tablets/capsules/drops (e.g. Lacteeze®, Lactaid®)

**Irritable Bowel Syndrome**

- diagnosis of exclusion in older child/adolescent; may be similar to recurrent abdominal pain
- management: encourage high fibre diet, reassurance, medications (cAMP inhibitors) rarely for refractory cases

**Celiac Disease**

- see Gastroenterology, G18
- in children: presents at any age, usually 6-24 mo with the introduction of gluten in the diet
- FTT with poor appetite, irritability, apathy, rickets, wasted muscles, flat buttocks, rarely distended abdomen
- GI symptoms: anorexia, nausea, vomiting, edema, anemia, abdominal pain
- non-GI manifestations: iron-deficiency anemia, dermatitis herpetiformis, dental enamel hypoplasia, osteopenia/osteoporosis, short stature, delayed puberty, behavioural changes
- associated with other autoimmune disorders

**Milk Protein Allergy**

**Pathophysiology**
- immune-mediated mucosal injury (IgE and non-IgE-mediated)

**Clinical Presentation**
- up to 50% of children intolerant to cow’s milk may be intolerant to soy protein as well
- often history of atopy
- can present as:
  - proctocolitis: mild diarrhea, small amounts of bloody stools (common presentation in young infant)
  - enterocolitis: vomiting, diarrhea, anemia, hematochezia
  - enteropathy: chronic diarrhea, hypoalbuminemia
Management
• casein hydrolysate formula (dairy-free e.g. Nutramigen®, Pregestimil®) or mother may remove all milk protein from diet and continue breastfeeding (with adequate calcium and vit D intake)

Inflammatory Bowel Disease (IBD)
• see Gastroenterology, G19

Cystic Fibrosis (CF)
• see Respirology, P95

Constipation
• decreased stool frequency (<3 stools/wk) and/or stool fluidity (hard, pellet-like)

FUNCTIONAL CONSTIPATION
• 99% of cases of constipation

Pathophysiology
• lack of fibre in diet or change in diet, poor fluid intake, behavioural
  • infants: often occurs when introducing cow's milk after breast milk due to high fat and solute content, lower water content
  • toddlers/older children: can occur during toilet training, or due to pain on defecation, stool withholding

Management
• clean out: PEG 3350 flakes, picosalax, biscodyl, PEGlyte
• maintenance: adequate fluid intake (if <6 mo, 150 mL/kg/d), adequate dietary fibre, stool softening (PEG 3350, mineral oil), appropriate toilet training technique
• months of maintenance treatment is often required

Complications
• pain retention cycle: anal fisses + pain → withhold passing stool → chronic dilatation ± overflow incontinence

HIRSCHSPRUNG’S DISEASE (Congenital Aganglionic Megacolon)
• see General Surgery, GS63

OTHER ORGANIC DISORDERS CAUSING CONSTIPATION
• endocrine: hypothyroidism, DM, hypercalcemia
• neurologic: spina bifida
• anatomic: bowel obstruction, anus (imperforate, atresia, stenosis)
• drugs: lead, chemotherapy, opioids

Abdominal Pain

ACUTE ABDOMINAL PAIN

History
• description of pain (location, radiation, duration, constant vs. colicky, relation to meals)
• associated symptoms: nausea, vomiting, diarrhea, fever

Physical Examination
• abdominal exam, peritoneal signs, bowel sounds, rectal exam, rash

Investigations
• CBC, differential, urinalysis to rule out urinary tract infection (UTI)

</tbody>
</table>

## APPENDICITIS
- see [General Surgery], GS28
- most common cause of acute abdomen after 5 yr of age
- clinical features: low grade fever, abdominal pain, anorexia, N/V (after onset of pain), peritoneal signs (generalized peritonitis is a common presentation in infants/young children)
- treatment: surgical
- complications: perforation (common in young children), abscess

## INTUSSUSCEPTION
- telescoping of segment of bowel into distal segment causing ischemia and necrosis

### Epidemiology
- 90% idiopathic, children with CF or GJ tube at significantly increased risk
- 50% between 3-12 mo, 75% before 2 yr of age

### Pathophysiology
- usual site: ileocecal junction; jejunum in children with GJ tubes
- lead point of telescoping segment may be swollen Peyer’s patches, Meckel’s diverticulum, polyp, malignancy, Henoch-Schönlein Purpura

### Clinical Presentation
- “classic triad” (only in 10-15% of patients)
- sudden onset of recurrent, paroxysmal, severe periumbilical pain with pain-free intervals
- later vomiting (may be bilius) and rectal bleeding (late finding)
- shock and dehydration

### Diagnosis
- U/S, air enema

### Management
- air enema can be therapeutic (reduces intussusceptions in 75% of cases), reduction under hydrostatic pressure, surgery rarely needed

## Chronic Abdominal Pain

### Epidemiology
- prevalence: 10% of school children (peak at 8-10 yr), F>M

### Etiology
- organic (<10%)
  - gastrointestinal
    - constipation (cause vs. effect), infectious
    - IBD, esophagitis, peptic ulcer disease, lactose intolerance
    - anatomic anomalies, masses
    - pancreatic, hepatobiliary
  - genitourinary causes
  - recurrent urinary tract infections, nephrolithiasis, chronic PID, Mittelschmerz
  - neoplastic
  - Functional/Recurrent Abdominal Pain (RAP) (90%)
Clinical Presentation
- clustering episodes of vague, crampy periumbilical/epigastric pain, vivid pain description
- seldom awakens child from sleep, less common on weekends
- aggravated by exercise, alleviated by rest
- psychological factors related to onset and/or maintenance of pain, school avoidance
- psychiatric comorbidity: anxiety, somatoform, mood, learning disorders, sexual abuse, eating disorders, elimination disorders
- diagnosis of exclusion

Investigations
- CBC, ESR, urinalysis, stools for O&P, C&S, occult blood

Management
- continue to attend school
- manage any emotional or family problems, counselling
- trial of high fibre diet, trial of lactose-free diet
- reassurance

Prognosis
- pain resolves in 30-50% of kids within 2-6 wk of diagnosis
- 30-50% of kids with RAP have functional pain as adults (e.g. irritable bowel syndrome)

Abdominal Mass

Upper Gastrointestinal Bleeding
- see Gastroenterology, G25

Lower Gastrointestinal Bleeding
- see Gastroenterology, G27

Epidemiology
- acute:
  - infectious (bacterial, parasitic)
  - antibiotic-induced (C. difficile)
  - necrotizing enterocolitis in preterm infants
  - anatomic
  - malrotation/volvulus, intussusception
  - Meckel's diverticulitis
  - anal fissures, hemorrhoids
  - vascular/hematologic
  - Henoch-Schönlein Purpura (HSP)
  - hemolytic uremic syndrome (HUS)
  - coagulopathy
- chronic:
  - anal fissures (most common)
  - colitis
  - inflammatory bowel disease (IBD)
  - allergic (milk protein)
  - structural
  - polyps (most are hamartomas)
  - neoplasms (rare)
  - coagulopathy

Physical Examination
- hemodynamic status, evidence of FTT, fever
- anal and rectal exam: tags, fissures, anal fistulas, polyps, foreign body, blood per rectum
- stool appearance
- NG aspirate
- lower GI bleed may present as melena (if it involves the small bowel) or hematochezia
Investigations
- stool cultures (C&S, *C. difficile* toxin)
- urinalysis and microscopy
- CBC, smear, differential, ESR, CRP, electrolytes, urea, creatinine, INR, PTT, albumin, iron studies, amoeba titers
- radiologic investigations
- abdominal x-ray to rule out obstruction
- Meckel's radionucleide scan

Management
- acute stabilization: ABCs, volume and blood replacement, bowel rest (NPO, NG tube)
- once stable, endoscopy and/or surgery as indicated

Genetics, Dysmorphisms and Metabolism

Genetic Anomalies

Minor and Major Anomalies
- minor anomaly: an unusual anatomic feature that is of no serious medical or cosmetic consequence to the patient
- major anomaly: anomaly that creates significant medical, surgical or cosmetic problems for the patient

Mechanism for Anomalies
- malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
- disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. bone dysplasia)

Multiple Anomalies
- association: non-random occurrence of multiple independent anomalies that appear together more than would be predicted by chance but are not believed to have a single etiology (e.g. VACTERL)
- sequence: related anomalies that come from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence)
- syndrome: a pattern of anomalies that occur together and are caused by a single known or unknown cause (e.g. Down syndrome)

Approach to the Dysmorphic Child
- genetic disorders are the most common cause of infant death in developed countries

General Approach to the Dysmorphic Child
- Are the anomalies major or minor?
- What is the mechanism underlying the anomaly?
- Do the anomalies fit as part of an association, sequence or syndrome?

History
- prenatal/obstetrical history (see Obstetrics, OB2)
- complete 3 generation family pedigree: consanguinity, stillbirths, neonatal deaths, specific illnesses, intellectual disability, multiple miscarriages, ethnicity
Physical Examination

Investigations
- prenatal counselling and assessing risk of recurrence
- serial photographs if child is older
- x-rays for bony abnormalities
- cytogenetic studies
  - karyotype if recognized syndrome
  - chromosome microarray analysis (array comparative genomic hybridization) if developmental delay with multiple congenital anomalies
  - fluorescent in situ hybridization (FISH) if microdeletion syndrome or trisomy suspected
  - chromosomes in skin fibroblasts if mosaicism suspected and microarray is normal
- biochemistry: specific enzyme assays
- single gene testing

Genetics

MECHANISMS OF INHERITANCE

Mendelian Inheritance
- disorders caused by mutation of one or both copies of a gene, inherited in one of two patterns:
  - autosomal: encoded by genes on one of 22 pairs of autosomes (chromosomes 1-22)
  - X-linked: encoded by a gene on the X chromosome

Triplet Repeat Expansions
- disorder in which trinucleotide repeats in certain genes exceed the normal number and result in altered expression of the gene or production of an abnormal protein (e.g. Fragile X syndrome, spinocerebellar ataxias, myotonic dystrophy, Huntington disease)

Imprinting Disorders
- imprinting: epigenetic process that involves methylation or acetylation of DNA, affecting gene expression
- imprinted genes are expressed differently depending on whether they are inherited from the mother or the father (parent-of-origin gene expression)
- occur when imprinted alleles are silenced (e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome)

Mitochondrial Inheritance
- disorders caused by mutations of the DNA present in mitochondria
- inheritance pattern: mother passes on the defect to all her children; father does not pass on the defect since embryo only receives mitochondria from the mother (in the egg)

METHODS OF GENETIC TESTING
- microarray analysis
  - a microarray is a collection of DNA probes attached to a solid surface
  - microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome
  - indicated when there is developmental delay + one or more major malformations
- **FISH**
  - usually to identify a gain or loss of chromosomal material
- **karyotype**
  - microscopic analysis of all 46 chromosomes with a special stain that shows large changes in the number or structure of chromosomes

### Genetic Syndromes

</tbody>
</table>

Muscular Dystrophy (MD)

- group of inherited diseases characterized by progressive skeletal and cardiac muscle degeneration

DUCHENNE MUSCULAR DYSTROPHY (DMD)

Epidemiology
- 1:4000 males

Etiology
- X-linked recessive: 1/3 spontaneous mutations, 2/3 inherited mutations
- missing structural protein (dystrophin) ➔ muscle fibre fragility ➔ fibre breakdown ➔ necrosis and regeneration

Clinical Presentation
- proximal muscle weakness by age 3, positive Gower’s sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

Gower’s Sign
Child uses hands to “climb up” the legs to move from a sitting to a standing position.
Diagnosis
- molecular genetic studies of dystrophin gene (DMD) (first line)
- family history (pedigree analysis)
- increased CK (50-100x normal) and lactate dehydrogenase
- elevated transaminases
- muscle biopsy, electromyography (EMG)

Management
- supportive (e.g. physiotherapy, wheelchairs, braces), prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vit D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

Complications
- patient usually wheelchair-bound by 12 yr of age
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in 2nd-3rd decade

Metabolic Disease
- an inherited disorder of metabolism; often autosomal recessive
- infants and older children may present with failure to thrive (FTT) or developmental delay
- in Ontario, universal newborn screening looks for: 9 organic acid disorders, 6 amino acid disorders, 5 fatty acid oxidation defects, 3 hemoglobinopathies, 2 endocrinopathies, galactosemia, biotinidase deficiency, cystic fibrosis, and hearing loss
- types of disorders
  - proteins: PKU, tyrosinemia, organic acid disorders, urea cycle defects
  - carbohydrates: galactosemia, glycogen storage diseases
  - fats: fatty acid oxidation defects
  - organelle disorders: congenital disorders of glycosylation, mucopolysaccharidosis

Clinical Manifestations
- vomiting and acidosis after feeding initiation (amino acid or carbohydrate metabolic disorder)
- hepatosplenomegaly (metabolites accumulate in the liver)
- neurologic syndrome: acute and chronic encephalopathy, intellectual disability, megalencephaly (mucopolysaccharide disorders)
- severe acidosis (aminoaciduria), hyperammonemia (urea cycle and organic acid disorders)
- growth retardation, seizures, coma, hypoglycemia
- autonomic manifestations (e.g. pallor, sweating, tremor)

Physical Exam
- odour: burnt sugar, sweaty feet, musty, ammonia-like
- skin: hypo/hyperpigmentation, rash, xanthomas
- hair: alopecia, hirsutism, abnormal architecture, fair colouring
- eyes: cornea (clouding, crystals), lens (cataracts, dislocation), retina (macular cherry red spot, pigment retinopathy, optic atrophy)

Initial Investigations
- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, ABGs (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects and glycogen storage diseases)
- lactate, ammonium (hyperammonemia with urea cycle defects), plasma Ca$^{2+}$ and Mg$^{2+}$
- routine urinalysis: ketonuria must be investigated
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, plasma amino acid screen, urine organic acids, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)
- storage diseases: urine mucopolysaccharide and oligosaccharide screen

Metabolic disease must be ruled out in any newborn who becomes acutely ill after a period of normal behaviour and development or with a family history of early infant death even if the newborn screen is negative.
**Phenylketonuria (PKU)**

**Epidemiology**
- 1:10,000; autosomal recessive disease

**Etiology**
- deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to build up of toxic metabolites
- mothers who have PKU may have infants with congenital abnormalities

**Clinical Presentation**
- baby is normal at birth, then develops a musty odour, eczema, hypertonia, tremors, and mental retardation
- hypopigmentation due to low tyrosine (fair hair, blue eyes)

**Management**
- PKU screening at birth
- dietary restriction of phenylalanine starting within the first 10 d of life
- duration of dietary restriction controversial – lifelong or until end of puberty; should be resumed during pregnancy to maintain normal phenylalanine levels

**Galactosemia**

**Epidemiology**
- 1:60,000; autosomal recessive disease

**Etiology**
- most commonly due to deficiency of galactose-1-phosphate uridylyltransferase leading to an inability to process lactose/galactose

**Clinical Presentation**
- signs of liver and renal failure, jaundice, FTT and cataracts with ingestion of lactose/galactose

**Management**
- elimination of galactose from the diet (e.g. dairy, breast milk)
- most infants are fed a soy-based diet

**Complications**
- increased risk of sepsis, especially E. coli
- if the diagnosis is not made at birth, liver and brain damage may become irreversible

**Hematology**

**Approach to Anemia**

![Figure 10. Anemia](image)

- Decreased reticulocytes:
  - Microcytic: Iron deficiency anemia, Thalassemia, Anemia of chronic disease, Lead poisoning, Sideroblastic anemia
  - Normocytic: Anemia of chronic disease, renal failure, marrow infiltration
  - Macrocytic: Megaloblastic anemia, marrow failure

- Increased reticulocytes:
  - Hemolysis: Hemoglobinopathies, Membrane problem, Enzyme problem, Immune hemolysis
  - Extrinsic to RBC: Antibody mediated
  - Intrinsic to RBC: Membrane problem, Enzyme problem

- Sickle cell disease, Thalassemia
- Hemolytic anemia, Membrane problem

- G6PD deficiency
- TTP, HUS

*Figure 10. Anemia*
**Physiologic Anemia**

- high Hb (>170 g/L) and reticulocyte count at birth is caused by a hypoxic environment in utero
- after birth, levels start to fall due to shorter fetal RBC lifespan, decreased RBC production (during first 6-8 wk of life, there is virtually no erythropoiesis due to new O₂ rich environment), and increasing blood volume secondary to growth
- lowest levels about 100 g/L at 8-12 wk age (earlier and more exaggerated in premature infants); levels rise spontaneously with activation of erythropoiesis
- no treatment usually required

**Iron Deficiency Anemia**

- most common cause of childhood anemia
- full term infants exhaust iron reserves by 6 mo of age
- premature infants have lower reserves, therefore exhausted by 2-3 mo of age
- common diagnosis between 6 mo-3 yr and 11-17 yr due to periods of rapid growth and increased iron requirements; adolescents also have poor diet and menstrual losses

**Etiology**

- dietary risk factors
- age >6 mo: <2 servings/d of iron-fortified cereal, red meat, or legumes
- age <12 mo: use of low-iron formula (<10 mg/L), primary diet of cow, goat or soy milk
- age 1-5 yr: >20 oz/d of non-fortified milk
- blood loss
  - iatrogenic: repeated blood sampling (especially in hospitalized neonates)
  - allergic: cow’s milk protein-induced colitis

**Clinical Manifestation**

- usually asymptomatic until marked anemia, pallor, fatigue, pica (eating non-food materials), tachycardia, systolic murmur

**Investigations**

- CBC: low Hb, MCV and MCH, reticulocyte count normal or high (absolute number low)
- Mentzer index (MCV/RBC) can help distinguish iron deficiency anemia from thalassemia
  - ratio <13 suggests thalassemia; ratio >13 suggests iron deficiency
- blood smear: hypochromic, microcytic RBCs, pencil shaped cells, poikilocytosis
- iron studies: low ferritin, other (low iron, high TIBC)
- initial therapy: trial of iron

**Prevention**

- breastfed term infants: begin iron supplementation (1 mg/kg/d) at 4-6 mo, continuing until able to eat ≥2 feeds/d of iron-rich foods
- non-breastfed (<50% of diet) term infants: give iron-fortified formula from birth
- premature infants: give iron supplements from 1 mo through to 1 yr of age
- no cow’s milk until 9-12 mo, early introduction of red meat and iron-rich vegetables: total daily iron should be 11 mg (age 6-12 mo), 7 mg (age 1-3 yr)
- universal screening of Hb levels recommended at 9 mo
- children at risk (premature, LBW, low SES, First Nations, etc.) fed whole cow’s milk in their first year

**Management**

- encourage diverse, balanced diet, limit homogenized milk to 16-20 oz/d
- oral iron therapy: 6 mg/kg/d elemental iron, divided bid to tid, for 3 mo
  - increased reticulocyte count in 2-3 d (peaks day 5-7)
  - increased hemoglobin in 4-30 d
  - repletion of iron stores in 1-3 mo
  - repeat hemoglobin levels after 1 mo of treatment
- poor response to oral iron therapy: non-compliance, medication intolerance, ongoing blood loss, IBD, celiac disease, incorrect diagnosis

**Complications**

- can cause irreversible effects on development if untreated (behavioural and intellectual deficiencies)
- angular chelitis, glossitis, koilonychia (spoon nails)
**Anemia of Chronic Disease**

- most often normocytic, normochromic (microcytic, hypochromic may occur with chronic infection/malignancy)
- multifactorial in origin
- chronic inflammatory states including juvenile idiopathic arthritis (JIA), chronic infections, chronic renal failure, and malignancies
- iron stores are variable and ferritin levels are unreliable (acute phase reactant); therefore bone marrow assessment may be necessary for diagnosis
- anemia of chronic renal failure predominantly caused by decreased erythropoietin (EPO) production; treat with EPO if necessary

**Sickle Cell Disease (SCD)**

- see Hematology, H19
- identification of specific genotypes important due to differences in frequency, type and severity of clinical complications (most severe: SS, less severe: SC, S-β thalassemia, rare: SD)

**Epidemiology**
- increased incidence in people of African and Mediterranean heritage

**Pathophysiology**
- caused by a genetic defect at position 6 of the β-globin genes
  - HbS: single amino acid replacement (glutamic acid → valine)
  - RBCs sickle under conditions of stress (low pO₂, dehydration, fever, acidosis)
  - acute intravascular sickling results in infarction of tissue (capillary occlusion and thrombosis of spleen, lungs, bones, brain, digits)
  - hemolysis causes chronic, well-compensated, normochromic normocytic anemia

**Presentation**
- clinical disease presents at 5-6 mo of age after fall in fetal Hb
- anemia, fever (medical emergency – infection is leading cause of death in SCD), jaundice, splenomegaly, crisis (dactylitis is often the first presentation)
- sickle cell trait: asymptomatic (may have microscopic hematuria and later isothenuria)

**Types of Crises**
- vaso-occlusive crisis
  - due to obstruction of blood vessels by rigid, sickled cells → tissue hypoxia → cell death; presents as fever and pain in any organ; most commonly in long bones of arms and legs, chest, abdomen, CNS (stroke), dactylitis (in young children), priapism
  - acute chest crisis: fever, chest pain, progressive respiratory distress, increased WBC count, pulmonary infiltrates
  - aplastic crisis: depression of erythropoiesis (decreased reticulocyte count to <1%, decreased Hb), generally associated with infection (especially parvovirus B19)
  - acute splenic sequestration: sudden, massive pooling of red cells in spleen, splenomegaly, tender spleen, acute fall in hemoglobin, shock, increased reticulocyte count

**Functional Asplenia**
- splenic dysfunction usually by 5 yr of age secondary to auto-infarction
- susceptible to infection by encapsulated organisms (especially S. pneumoniae)
- all individuals with SCD should be on prophylactic antibiotics, and be vaccinated against pneumococcal/meningococcal/H. influenzae type b, along with hepatitis B and influenza
- febrile episodes require immediate evaluation: rule out bacteremia, meningitis, acute chest syndrome, and osteomyelitis (commonly due to Salmonella in SCD)

**Other Manifestations**
- long term complications: growth delay, bony abnormalities (e.g. avascular necrosis (AVN) of femoral head), gallstones, retinopathy, restrictive lung disease (screen with PFTs), cardiomyopathy (screen with Echo), and pulmonary hypertension

**Management**
- acute crises
  - fluids (1.5x maintenance; 1x maintenance only if in chest crisis), analgesia (opioid, multi-modal), antibiotics (e.g. 3rd generation cephalosporins), incentive spirometry and ambulation to decrease risk of chest crisis
  - straight transfusions for symptomatic/significant anemia, evolving chest crisis
  - RBC exchange transfusion for impending stroke, severe chest crisis, persistent priapism
  - O₂ if respiratory distress or chest crisis (with incentive spirometry)
  - cultures and CBC if febrile, reticulocyte counts, CXR or LP if indicated
• chronic
  ▪ early aggressive treatment of infections, prophylactic antibiotics (daily oral penicillin)
  ▪ pneumococcal, meningococcal, hepatitis B, Hib, and influenza vaccines
  ▪ folate supplementation
  ▪ hydroxyurea if frequent crises, history of acute chest syndrome (raises HbF level)
  ▪ transcranial Doppler to assess risk of stroke
  ▪ chronic transfusion program if history of stroke or abnormal transcranial Doppler
  ▪ genetic counselling and education
  ▪ annual fundoscopic exam (after 10 yr old)
  ▪ bi-annual screening for pulmonary hypertension (after 12 yr old)
  ▪ bi-annual chemistry and urinanalysis to monitor organ dysfunction

Thalassemia

• see Hematology, H18

Hereditary Spherocytosis

• see Hematology, H21

Glucose-6-Phosphate Dehydrogenase (G6PD) Deficiency

• see Hematology, H22

Bleeding Disorders

• see Hematology, H25

Coagulation Defects
• bleeding into joints (hemarthroses) and muscles
• large spreading ecchymoses and hematomas

Platelet Abnormalities
• petechiae, purpura, bruises, mucocutaneous bleeding (e.g. epistaxis, gingival bleeding), menorrhagia, prolonged bleeding from superficial cuts

Immune Thrombocytopenic Purpura (ITP)

Epidemiology
• most common cause of thrombocytopenia in childhood
• peak age: 2-6 yr, M=F
• incidence 5:100,000 children per year

Etiology
• caused by autoantibodies that bind to platelet membranes → Fc-receptor mediated splenic uptake → destruction of platelets
Clinical Presentation

- 50% present 1-3 wk after viral illness (URTI, chicken pox)
- sudden onset of petechiae, purpura, epistaxis in an otherwise well child
- clinically significant bleed in only 3% (severe bleed more likely with platelet count <10) with <0.5% risk of intracranial bleed
- no lymphadenopathy, no hepatosplenomegaly
- labs: thrombocytopenia with normal RBC, WBC
- bone marrow aspirate only if atypical presentation (≥1 cell line abnormal, hepatosplenomegaly)
- differential diagnosis: leukemia, drug-induced thrombocytopenia, HIV, infection (viral), autoimmune (SLE, ALPS)

Management

- observation vs. pharmacologic intervention highly debated; spontaneous recovery in >70% of cases within 3 mo
- treatment with IVIg or prednisone if mucosal or internal bleeding, platelets <10, or at-risk of significant bleeding (surgery, dental procedure, concomitant vasculitis or coagulopathy)
- life-threatening bleed: additional platelet transfusion ± emergency splenectomy
- persistent (>3-12 mo) or chronic (>12 mo): re-evaluate; treat if symptoms persist
- supportive: avoid contact sports and ASA/NSAIDs

Hemophilia

- see Hematology. H29

von Willebrand’s Disease

- see Hematology. H28

BT = bleeding time; VIII:C = Factor VIII coagulant activity; vWF = von Willebrand’s Factor; DIC = disseminated intravascular coagulation

Oncology

- cancer is the second most common cause of death after injuries in children after 1 yr of age
- cause is rarely known, but increased risk for:
  - chromosomal syndromes (e.g. Trisomy 21)
  - prior malignancy
  - neurocutaneous syndromes
  - immunodeficiency syndromes
  - family history
  - exposure to radiation, chemicals, biologic agents
- leukemias are the most common type of pediatric malignancy (40%), followed by brain tumours (20%), and lymphomas (15%)
- some malignancies are more prevalent in certain age groups
  - newborns: neuroblastoma, Wilms’ tumour, retinoblastoma
  - <1yr: infancy and childhood: leukemia, neuroblastoma, Wilms’ tumour, retinoblastoma
  - adolescence: lymphoma, gonadal tumours, bone tumours
- unique treatment considerations in pediatrics because radiation, chemotherapy, and surgery can impact growth and development, endocrine function and fertility
- good prognosis: treatments have led to remarkable improvements in overall survival and cure rates for many pediatric cancers (>80%)

Corticosteroids versus Intravenous Immune Globulin for the Treatment of Acute Immune Thrombocytopenic Purpura in Children: A Systematic Review and Meta-analysis of Randomized Controlled Trials

J Pediatr 2005;147:521-527

Study: Meta-analysis of 10 RCTs from 1985-2003. RCTs compared corticosteroids and IVIG in the treatment of pediatric ITP, and had to include patient platelet counts.

Patients: 596 children 3 mo-18 yr of age who were presenting for the first time with primary acute ITP, with no other underlying condition.

Intervention: Corticosteroids and IVIG at any dose. Corticosteroid treatments included methylprednisolone 10-30 g/kg/d and prednisone 2-4 g/m²/d. IVIG dosing ranged from 0.5-1 g/kg/d.

Main Outcome: Primary outcome was platelet levels >20,000/mm³ (20 x 10⁹/L) at 48 h after treatment. (This outcome was chosen because intracranial hemorrhage rarely occurs at platelet above 20). Secondary outcomes included incidence of ICH.

Results: The relative risk (RR) of reaching a platelet count >20,000/mm³ at 48 h was 0.74 (95% CI 0.65-0.85) for corticosteroids versus IVIG (at any dose), with a NNT of 4.55 (95% CI 3.23-7.69).

Subgroup analyses by dosing favoured IVIG in 6/10 dose comparisons. Only 3/586 children developed ICH – two were treated with corticosteroids and one with IVIG.

Summary: Children treated with corticosteroids are less likely to have a platelet count >20,000/mm³ than children treated with IVIG after 48 h of therapy. However, optimal dosing of IVIG is unclear, and impact of IVIG versus corticosteroids on ICH and mortality are unclear.

Extensive bruising in the absence of lab abnormalities: consider child abuse.
Leukemia

- see Hematology, H35, H38, H41, H46

Epidemiology
- mean age of diagnosis 2-5 yr but can occur at any age
- heterogeneous group of diseases:
  - acute lymphoblastic leukemia (ALL) (80%)
  - acute myeloblastic leukemia (AML) (15%)
  - chronic myelogenous leukemia (CML) (<5%)
- children with Down syndrome are 15x more likely to develop leukemia

Clinical Presentation
- infiltration of leukemic cells into bone marrow results in bone pain, and bone marrow failure (anemia, neutropenia, thrombocytopenia)
- infiltration into tissues results in lymphadenopathy, hepatosplenomegaly, CNS manifestations, testicular disease
- fever, fatigue, weight loss, bruising, and easy bleeding

Management
- combination chemotherapy using non-cross resistant chemotherapy agents

Prognosis
- 80-90% 5-yr event-free survival for ALL, 50-60% 5-yr survival for AML
- patients are stratified into standard risk and high risk based on WBC and age; other prognostic factors include presence of CNS/testicular disease, immunophenotype, cytogenetics, and initial response to therapy (most important prognostic variable)

Lymphoma

- see Hematology, H42

Epidemiology
- Hodgkin lymphoma: incidence is bimodal, peaks at ages 15-34 and >50 yr old
- Non-Hodgkin lymphoma: incidence peaks at 7-11 yr

Clinical Presentation
- Hodgkin lymphoma:
  - most common presentation is persistent, painless, firm, cervical or supraclavicular lymphadenopathy
  - can present as persistent cough or dyspnea (secondary to mediastinal mass) or less commonly as splenomegaly, axillary or inguinal lymphadenopathy
  - constitutional symptoms (B symptoms) in 30% of children
- Non-Hodgkin lymphoma:
  - generally categorized into lymphoblastic, large cell, and Burkitt’s/Burkitt’s-like lymphoma
  - rapidly growing tumour with distant metastases (unlike adult non-Hodgkin lymphoma)
  - signs and symptoms related to disease site: most commonly abdomen, chest (mediastinal mass), head and neck region

Management
- Hodgkin lymphoma:
  - combination chemotherapy and radiation
  - aimed at limiting cumulative doses of anthracyclines (toxic to heart) and alkylators (risk of second malignancy, infertility) and limiting dose and field of radiation
  - increasing role for use of PET scanning to assess early disease response and plan therapy.
- Non-Hodgkin lymphoma:
  - combination chemotherapy
  - no added benefit of radiation in pediatric protocols.

Prognosis
- Hodgkin lymphoma: >90% 5-yr survival
- Non-Hodgkin lymphoma: 75-90% 5-yr survival

Brain Tumours

- see Neurosurgery, NS10, NS38
**Wilms’ Tumour (Nephroblastoma)**

**Epidemiology**
- usually diagnosed between 2-5 yr; M=F
  - most common primary renal neoplasm of childhood
  - 5-10% of cases both kidneys are affected (simultaneously or in sequence)

**Differential Diagnosis**
- hydronephrosis, polycystic kidney disease, renal cell carcinoma, neuroblastoma

**Clinical Presentation**
- 80% present with asymptomatic, unilateral abdominal mass
- may also present with hypertension, gross hematuria, abdominal pain, vomiting
- may have pulmonary metastases at time of diagnosis (respiratory symptoms)

**Associated Congenital Abnormalities**
- WAGR syndrome (Wilms’ tumour, Aniridia, Genital anomalies, mental Retardation) with 11p13 deletion
- Beckwith-Wiedemann syndrome
  - characterized by enlargement of body organs (especially tongue), hemihypertrophy, renal medullary cysts, and adrenal cytomegaly
  - also at increased risk for developing hepatoblastoma, and less commonly adrenocortical tumours, nephroblastomas and rhabdomyosarcomas
- Denys-Drash syndrome
  - characterized by gonadal dysgenesis and nephropathy leading to renal failure

**Management**
- staging ± nephrectomy
- chemotherapy; radiation for higher stages

**Prognosis**
- 90% long-term survival

---

**Neuroblastoma**

**Epidemiology**
- most common cancer occurring in first year of life
- neural crest cell tumour arising from sympathetic tissues (neuroblasts)

**Clinical Presentation**
- can originate from any site in sympathetic nervous system, presenting as mass in neck, chest or abdomen mass (most common site is adrenal gland)
- signs and symptoms of disease vary with location of tumour
  - thoracic: dyspnea, Horner's syndrome
  - abdomen: palpable mass
  - spinal cord compression
- metastases are common at presentation (>50% present with advanced stage disease)
  - usually to bone or bone marrow (presents as bone pain, limp)
  - can also present with periorbital ecchymoses, abdominal pain, emesis, fever, weight loss, anorexia, hepatomegaly, “blueberry muffin” skin nodules
- paraneoplastic: hypertension, palpitations, sweating (from excessive catecholamines), diarrhea, FTT (from vasoactive intestinal peptide secretion), opsomyoclonus
- diagnostic criteria (either of the following):
  - unequivocal histologic diagnosis from tumour tissue biopsy
  - evidence of metastasis to bone marrow (“rosettes”) on aspirate analysis, with concomitant elevation of urine or serum catecholamine metabolite (VMA, HVA) levels

**Management**
- depends on prognostic factors and may include combination of: surgery, radiation, chemotherapy, bone marrow transplantation

**Prognosis**
- prognosis is often poor due to late detection
- good prognostic factors:
  - “age and stage” are important determinants of better outcome: 12-18 mo, stage I, II, IV-S disease (“S” designates a “Special” classification only pertaining to infants)
  - primary site: posterior mediastinum and neck
  - low serum ferritin
  - specific histology
  - tumour cell markers: aneuploidy, absent MYCN oncogene amplification
**Bone Tumours**

- see Orthopedics, OR42

**Febrile Neutropenia**

- see Infectious Diseases, ID39

**Tumour Lysis Syndrome**

- see Hematology, H50

**Hyperleukocytosis**

- total WBC >100 x 10^9/L
- common presenting feature of leukemia
- medical emergency
- leukostasis = symptomatic hyperleukocytosis
  - presents clinically with respiratory or neurological distress caused by hyperviscosity of blood
  - risk of intracerebral hemorrhage, pulmonary leukostasis syndrome, tumour lysis syndrome
- management: fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)

**Lymphadenopathy**

**Clinical Presentations**

- features of malignant lymphadenopathy (LAD): firm, discrete, non-tender, enlarging, immobile, ± suspicious mass/imaging findings, ± 'B' symptoms
- fluctuance, warmth or tenderness are more suggestive of benign nodes (infection)

**Differential Diagnosis**

- infection:
  - viral: URTI, EBV, CMV, adenovirus, HIV
  - bacterial: S. aureus, GAS, anaerobes, *Mycobacterium* (e.g. TB), cat scratch disease (*Bartonella*)
  - other: fungal, protozoan, *Rickettsia*
- auto-immune: rheumatoid arthritis, SLE, serum sickness
- malignancy: lymphoma, leukemia, metastatic solid tumours
- storage diseases: Niemann-Pick, Gaucher’s
- other: sarcoidosis, Kawasaki disease, histiocytoses

**Investigations**

- generalized LAD
  - CBC and differential, blood culture
  - uric acid, LDH
  - ANA, RF, ESR
  - EBV/CMV/HIV serology
  - toxoplasma titre
  - fungal serology
  - CXR
  - TB tests
  - biopsy
- regional LAD
  - period of observation if asymptomatic
  - trial of oral antibiotics
  - ultrasound
  - biopsy (especially if persistent >6 wk and/or 'B' symptoms)

Most common cause of acute bilateral cervical LAD is viral illness.
Infectious Diseases

Fever

Definition
- fever: no generally accepted definition, a practical definition is >38°C oral or rectal
- fever without a source/focus: acute febrile illness (typically <10 d duration) with no cause of fever even after careful history and physical
- fever of unknown origin: daily or intermittent fevers for at least 2 consecutive weeks of uncertain cause after careful history and physical and initial laboratory assessment

Etiology
- infectious: anatomic approach (CNS, ears, upper and lower respiratory tract, GI, GU, skin, soft tissue, bones and joints, etc.)
- inflammatory: mainly autoimmune (Kawasaki Disease, JIA, IBD, SLE, etc.)
- malignancy: childhood cancers (leukemia, lymphoma, neuroblastoma, etc.)
- miscellaneous: dehydration, drugs and toxins, post-immunization, familial dysautonomia, factitious disorder, etc.

Diagnosis
- history: duration, height and pattern of fever, associated symptoms, exposures, constitutional symptoms, ethnic or genetic background, day care, sick contacts, travel
- physical: toxic vs. non-toxic, vitals, growth, complete exams of the: skin, HEENT, chest, abdomen, lymph nodes, genitalia
- investigations: guided by history, physical exam and clinical suspicion; see Figure 11 for guidelines for children from 0-3 yr old

Evaluation of Neonates and Infants with Fever
- several protocols exist that attempt to identify neonates and young infants at low risk of serious bacterial infection (e.g. Rochester Criteria)
  - such protocols are not as sensitive in the 1-28 d age group; therefore, febrile neonates should be considered high risk regardless of clinical presentation and laboratory findings

Management
- admit to hospital if appropriate
- treat the source if known
- replace fluid losses (e.g. from vomiting, diarrhea, etc.); maintenance fluid needs are higher in febrile child
- reassure parents that most fevers are benign and self-limited
- antipyretics are not necessary in most cases, but can be given if child is uncomfortable (acetaminophen and/or ibuprofen)

NOTES
1. Full Septic Workup (SWU) – blood C&S, CBC and differential, urine R&B, C&S, LP, CR if respiratory symptoms, stool C&S if GI symptoms
2. Follow-up is crucial – if adequate F/U is not assured, a more aggressive diagnostic and therapeutic approach may be indicated
3. Low-Risk (Rochester) Criteria
4. Considerable practice variation exists in terms of empiric antibiotics treatment
5. Important Principles – the younger the child, the greater the difficulty to clinically assess the degree of illness

Figure 11. Approach to the febrile child

Rochester Criteria – developed to identify infants ≤60 d of age with fever at low risk of serious bacterial infection

Acute Otitis Media (AOM)

Definition
All of:
1. presence of middle ear effusion (MEE)
2. presence of middle ear inflammation (MEI)
3. acute onset of symptoms of MEE and MEI

Epidemiology
- most frequent diagnosis in sick children visiting clinicians' offices and most common reason for antibiotic administration
- peak incidence between 6-15 mo; ~85% of children have >1 episode by 3 yr old
- seasonal variability: peaks in winter

Etiology
- primary defect causing AOM: Eustachian tube dysfunction/obstruction → stasis/colonization by pathogens
- bacterial: S. pneumoniae, non-typable H. influenzae, M. catarrhalis, Group A Streptococcus, S. aureus
- viral: RSV, influenza, parainfluenza, adenovirus
- commonly due to bacterial/viral co-infection

Risk Factors
- non-modifiable: young age, family history of OM, prematurity, orofacial abnormalities, immunodeficiencies, Down syndrome, race and ethnicity
- modifiable: lack of breastfeeding, day care attendance, household crowding, exposure to cigarette smoke and air pollution, pacifier use

Diagnosis
- history
  - acute onset of otalgia or ear tugging in a preverbal child, otorrhea, decreased hearing
  - unexplained irritability, fever, upper respiratory symptoms, poor sleeping, anorexia, nausea, vomiting and diarrhea
- physical
  - febrile
  - MEE on otoscopy: immobile tympanic membrane, acute otorrhea, loss of bony landmarks, opacification of TM, air-fluid level behind TM
  - MEI on otoscopy: bulging TM with marked discolouration (hemorrhagic, red, grey, or yellow)

Management
- observation for 48-72 h without antimicrobials may be appropriate since >80% of AOM in children resolve spontaneously
- criteria for watchful waiting approach:
  - child is >6 mo old
  - child does not have immunodeficiency, chronic cardiac or pulmonary disease, anatomical abnormalities of the head or neck, a history of complicated otitis media (suppurative complications of chronic perforation) or Down syndrome
  - the illness is not severe – otalgia appears to be mild and fever is <39ºC in the absence of antipyretics
  - parents are capable of recognizing signs of worsening illness and can readily access medical care if the child does not improve
- antimicrobials are indicated if child does not meet the criteria for watchful waiting or does not improve/worsens during observation (Table 23)
- maintain hydration
- symptomatic relief: acetaminophen, ibuprofen
- referral to otolaryngology for myringotomy and tympanostomy tubes may be warranted for recurrent infections (see Otolaryngology, OT39 for indications)

Table 23. Treatment of AOM

<table>
<thead>
<tr>
<th>Antimicrobial Agents for Acute Otitis Media (AOM)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>First-line treatment (no penicillin allergy):</strong></td>
</tr>
<tr>
<td>Amoxicillin: 75 mg/kg/d to 90 mg/kg/d divided three times per day</td>
</tr>
</tbody>
</table>

| **Second-line treatment:** |
| Cefuroxime axetil: 30 mg/kg/d divided twice per day |
| Clarithromycin: 15 mg/kg/d divided twice per day |
| Azithromycin: 10 mg/kg OD x 1 dose, then 5 mg/kg OD x 4 doses |
| Ceftriaxone: 50 mg/kg intramuscularly (or intravenously) x 1 dose |

If initial therapy fails (i.e. no symptomatic improvement after 2-3 d):
- Amoxicillin-clavulanate: 90 mg/kg/d amoxicillin, 6.4 mg/kg/d clavulanate divided twice per day for 10 d
- If AOM-related symptoms do not resolve with amoxicillin/clavulanate, a course of ceftriaxone 50 mg/kg/d intramuscularly (or intravenously) once per day x 3 doses could be considered

Management of Acute Otitis Media
Paediatr Child Health 2009;14:457-460
**Purpose:** Updates a previous document published in 1998.
**Study:** Evidence-based guideline by the Canadian Pediatric Society (CPS).
**Recommendations:** The watchful waiting approach (observation for 48-72 h without antibiotics) is appropriate except for:
- Children ≤ 6 mo
- Children with immunodeficiency
- Children with chronic cardiac or pulmonary disease
- Children with anatomical abnormalities of the head or neck
- History of complicated otitis media
- Children with Down syndrome
- Parent are incapable of recognizing signs of worsening illness or cannot readily access medical care if child does not improve
- If the child’s status worsens or fails to improve in 48-72 h, antibiotic treatment must be started.
Complications
- extracranial:
  - hearing loss and speech delay (secondary to persistent MEE), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
- intracranial:
  - meningitis, epideral and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis

Diphtheria

Definition
- upper respiratory bacterial illness caused by *Corynebacterium diptheriae*
- characterized by pharyngitis, low-grade fever, and nasopharyngeal pseudomembranes released by bacteria (with possible dermatologic, cardiac and/or nervous system involvement)

Epidemiology
- routine immunization has significantly reduced morbidity and mortality
- diphtheria now very rare

Etiology
- caused by lysogenized phage
- transmitted by direct contact or droplet spread; incubation period is 2-5 d

Risk Factors
- unvaccinated, immunocompromised, travel to or inhabitants of endemic countries

History
- early symptoms similar to a common cold: low-grade fever, sore throat, anorexia, malaise
- later symptoms (due to Diphtheria toxin): pallor, diaphoresis, stupor, coma

Physical
- grey membranes may cover tonsils and soft palate (at day 2-3); becomes greenish or black with hemorrhage
- cervical lymphadenopathy; “bull neck” secondary to submandibular edema in severe disease

Investigations
- throat culture (specifically state that diphtheria is suspected as some labs only look for group A *Streptococcus* on routine throat cultures)

Management
- treat based on clinical suspicion; awaiting culture results will postpone treatment and worsen prognosis
- diphtheria antitoxin
- penicillin G or erythomycin (halts furthers toxin production and prevents carrier state)

Prognosis
- 5-10% mortality for respiratory diphtheria
- complications: airway obstruction, recurrent laryngeal nerve palsy
- associated conditions: diphtheritic peripheral neuritis, myocarditis

Gastroenteritis

Definition
- inflammation (generally of infectious etiology) of the stomach and small intestine leading to illness characterized by nausea, vomiting and diarrhea

Epidemiology
- cause of 3-5 million childhood deaths annually worldwide
- viral gastroenteritis most commonly affects children aged 6 mo – 5 yr

Etiology
- viral (rotavirus, adenovirus, astrovirus), bacterial (*E. coli, Salmonella, Shigella, Campylobacter*) or parasitic (*Giardia lamblia*)
- rotavirus in ~50% of cases; primarily transmitted fecal-oral; incubation period of ~2 d
- antibiotic-associated (*Clostridium difficile*)

Risk Factors
- young age, day care attendance, infected household member, immunocompromised, antibiotic use (*Clostridium difficile*)
History
- non-specific: diarrhea, vomiting, fever, anorexia, headache, myalgias, abdominal cramps
- bacterial and parasitic agents more common in older children (2-4 yr): blood and/or mucous in stool, recent travel, consumption of unprocessed meats, recent antibiotic use or hospitalization
- recent infectious contacts: symptoms usually begin 24-48 h after exposure

Physical
- febrile
- dehydrated: must assess extent (see Dehydration, P79)

Investigations
- not usually necessary in young children
- stool analysis: leukocytes/erythrocytes suggests bacterial or parasitic etiology; pH <6 and presence of reducing substances suggests viral etiology

Management
- rehydration: replace deficits, ongoing loses and maintenance needs (see P79)
- oral rehydration therapy (ORT) preferred for mild-moderate dehydration in acute gastroenteritis
- antiemetics may reduce vomiting, but increase diarrhea
- regular diet of small frequent feeds recommended in mild illness
- may return to age-appropriate diet once re-hydrated and vomiting stops
- antibiotics or antiparasitic agents sometimes indicated in bacterial or parasitic gastroenteritis
- promote regular hand-washing and return to school 24 h after last diarrheal episode to prevent transmission
- oral rotavirus vaccine now available in Canada

Complications
- viral gastroenteritis usually self-limiting (lasts 3-7 d in most cases)
- adverse effects related to hypovolemia, shock, tissue acidosis, and rapid onset and over-correction of electrolyte imbalances
- death in severe dehydration (rare in developed countries)

HIV Infection
- see Infectious Diseases, ID41

Epidemiology
- 20-30% risk of vertical transmission in untreated HIV infected women, <1% with antiretroviral treatment during pregnancy and perinatally

Transmission
- infants and children: most often vertical (transplacentally in majority, maternal blood, exposure to infected secretions during delivery, breast milk)
- adolescents: sexual intercourse, needles (IV drug use and tattoos), blood products (rare)

Risk Factors
- HIV positive mother or mother with HIV positive partner
- IV illicit drug use (IVDU)
- unprotected sex
- sexual abuse
- receipt of blood products (rare)

Clinical Features of AIDS in Infants and Children
- signs and symptoms occur often within the first year, most within 2 yr of age
- encephalopathy, recurrent/persistent thrush, persistent diaper candidiasis, chronic interstitial pneumonitis (relatively common), opportunistic infections (especially Pneumocystis jiroveci (PJP) pneumonia), hepatomegaly, lymphadenopathy, failure to thrive

Management
- adequate nutrition (breastfeeding contraindicated in developed countries)
- suppression of HIV with HAART
- prompt treatment of infections
- prophylaxis:
  - TMP/SMX for PJP, azithromycin for mycobacterium avium complex (MAC); nystatin, ketoconazole, acyclovir if indicated
  - all routine immunizations (including live vaccines if well), but avoid oral-polio vaccine and BCG

</tbody>
</table>
Infectious Mononucleosis

Definition
- systemic viral infection caused by Epstein-Barr virus (EBV) with multivisceral involvement; often called "the great imitator"

Epidemiology
- peak incidence between 15-19 yr old
- ~50% of children in developed countries have a primary EBV infection by 5 yr old, but <10% of children develop clinical infection

Etiology
- EBV: a member of herpesviridae
- transmission is mainly through infected saliva ("kissing disease") and sexual activity (less commonly); incubation period of 1-2 mo

Risk Factors
- infectious contacts, sexually active, multiple sexual partners in the past

History
- prodrome: 2-3 d of malaise, anorexia
- infants and young children: often asymptomatic or mild disease
- older children and adolescents: malaise, fatigue, fever, sore throat, abdominal pain (often LUQ), headache, myalgia

Physical
- classic triad: febrile, generalized non-tender lymphadenopathy, pharyngitis/tonsillitis (exudative)
- ± hepatosplenomegaly
- ± periorbital edema, ± rash (urticarial, maculopapular or petichial) – more common after inappropriate treatment with β lactam antibiotics
- any “-itis” (including arthritis, hepatitis, nephritis, myocarditis, meningitis, encephalitis, etc.)

Investigations
- heterophil antibody test (Monospot® test)
  - 85% sensitive in adults and older children, but only 50% sensitive if <4 yr of age
  - false positive results with HIV, SLE, lymphoma, rubella, parvovirus
- EBV titres
- CBC and differential, blood smear: atypical lymphocytes, lymphocytosis, Downey cells, ± anemia, ± thrombocytopenia
- throat culture to rule out streptococcal pharyngitis

Management
- supportive: adequate rest, hydration, saline gargles and analgesics for sore throat
- splenic enlargement is often not clinically apparent so all patients should avoid contact sports for 6-8 wk
- if airway obstruction secondary to nodal and/or tonsillar enlargement is present (especially younger children), admit for steroid therapy
- acyclovir does NOT reduce duration of symptoms or result in earlier return to school/work

Prognosis
- most acute symptoms resolve in 1-2 wk, though fatigue may last for months
- short-term complications: splenic rupture, Guillain-Barré syndrome

Infectious Pharyngitis/Tonsillitis

Definition
- inflammation of the pharynx, especially the tonsils if present, causing a sore throat

Etiology
- viral (~80%): adenoviruses, enteroviruses, coxsackie, upper respiratory tract viruses, EBV, CMV
- bacterial (~20%): mainly Group A Streptococcus, M. pneumonia (older children), N. gonorrhoea (sexually active), C. diptheriae (unvaccinated)
- fungal: Candida

Epidemiology
- season: GAS pharyngitis more common in late winter or early spring; viral all yr long
- age: GAS pharyngitis peak incidence at 5-12 yr of age and uncommon <3 yr; viral pharyngitis affects all ages
History
• GAS: sore throat (may be severe), fever, malaise, headache, abdominal pain, N/V, absence of other URTI symptoms
• viral: sore throat (often mild), conjunctivitis, cough, rhinorrhea, hoarseness, diarrhea, flu-like symptoms (fever, malaise, myalgias)

Physical
• GAS: febrile, pharyngeal/tonsillar erythema and exudates, enlarged (>1 cm) and tender anterior cervical lymph nodes, palatal petechiae, strawberry tongue, scarlatiniform rash
• viral: afebrile, absent/mild tonsillar exudates, minor and non-tender adenopathy, viral exanthems

Investigations
• no single sign or symptom reliably identifies GAS as the causative organism in children with sore throat
• scores are used to predict if throat culture will be positive (e.g. McIsaac Criteria)
  ▪ these score systems have not been found to be sensitive or specific enough to diagnose GAS in children and adolescents with sore throat
• suspected diagnosis of GAS pharyngitis should be confirmed with a rapid streptococcal antigen test and a follow-up throat culture if the rapid test is negative

Management
• antibiotics (for group A Streptococcus/S. pyogenes)
  ▪ penicillin V or amoxicillin or erythromycin (if penicillin allergy) x 10 d
  ▪ can prevent rheumatic fever if given within 9 d of symptoms; does NOT alter risk of post-streptococcal glomerulonephritis
• supportive: hydration and acetaminophen for discomfort due to pain and/or fever
• follow-up: if uncomplicated course, no follow-up or post-antibiotic throat cultures needed
• prophylaxis: consider tonsillectomy for proven, recurrent streptococcal tonsillitis

Complications
• preventable with antibiotics: AOM, sinusitis, cervical adenitis, mastoiditis, retropharyngeal/peritonsillar abscess, sepsis
• immune-mediated complications: scarlet fever, acute rheumatic fever, post-streptococcal glomerulonephritis, reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A Streptococci (PANDAS)

SCARLET FEVER
• diffuse erythematous eruption
• delayed-type hypersensitivity reaction to pyrogenic exotoxin produced by Group A Streptococcus
• acute onset of fever, sore throat, strawberry tongue
• 24-48 h after pharyngitis, rash begins in the groin, axillae, neck, antecubital fossa; Pastia's lines may be present
• within 24 h, sandpaper rash becomes generalized with perioral sparing, non-pruritic, non-painful, blanchable
• rash fades after 3-4 d, may be followed by desquamation
• treatment is penicillin, amoxicillin, or erythromycin x 10 d

RHEUMATIC FEVER
• inflammatory disease due to antibody cross-reactivity following GAS infection
• affects ~1:10,000 children in developed world; much more prevalent in developing nations; peak incidence at 5-15 yr of age
• mainly a clinical diagnosis based on Jones Criteria (revised)
  ▪ requires 2 major OR 1 major and 2 minor (see sidebar) PLUS evidence of preceding strep infection [history of scarlet fever, group A streptococcal pharyngitis culture, positive rapid Ag detection test, anti-streptolysin O titers (ASOT)]
• treatment
  ▪ penicillin or erythromycin for acute course x 10 d
  ▪ prednisone if severe carditis
• secondary prophylaxis with daily penicillin or erythromycin
• complications:
  ▪ acute: myocarditis, conduction system aberrations (sinus tachycardia, atrial fibrillation), valvulitis (acute MR), pericarditis
  ▪ chronic: valvular heart disease (mitral and/or aortic insufficiency/stenosis), infectious endocarditis ± thromboembolic phenomenon
  ▪ onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever
POST-STREPTOCOCCAL GLOMERULONEPHRITIS
• glomerular immune complex disease following primary GAS infection of pharynx or skin
• most common in children aged 4-8 yr old; M>F
• antigen-antibody mediated complement activation with diffuse, proliferative glomerulonephritis
• occurs 1-3 wk following initial GAS infection (skin or throat)
• clinical presentation varies from asymptomatic, microscopic and macroscopic (cola coloured urine) hematuria to all features of nephritic syndrome (see P82)
• diagnosis is confirmed with elevated serum antibody titres against streptococcal antigens (ASOT, anti-DNAseB), low serum complement (C3)
• management:
  ▪ symptomatic: fluid and sodium restrictions; loop diuretics for hypertension and edema
  ▪ in severe cases, may require dialysis if renal function significantly impaired
  ▪ treat with penicillin or erythromycin if evidence of persistent GAS infection
• 95% of children recover completely within 1-2 wk; 5-10% have persistent hematuria

Meningitis

Definition
• inflammation of the meninges surrounding the brain and spinal cord

Epidemiology
• peak age: 6-12 mo; 90% of cases occur in children <5 yr old

Etiology
• viral: enteroviruses, herpes simplex virus (HSV)
• bacterial: age-related variation in specific pathogens (see Table 25)
• fungal and parasitic meningitis also possible
• most often due to hematogenous spread or direct extension from a contiguous site

Risk Factors
• unvaccinated
• immunocompromised: asplenia, diabetes mellitus, HIV, prematurity
• recent or current infections: AOM, sinusitis, orbital cellulitis,
• neuroanatomical: congenital defects, dermal sinus, neurosurgery, cochlear implants, recent head trauma
• exposures: day care centres, household contact, recent travel

History
• signs and symptoms variable and dependent on age, duration of illness and host response to infection
• infants: fever, lethargy, irritability, poor feeding, vomiting, diarrhea, respiratory distress, seizures
• children: fever, headache, photophobia, N/V, confusion, back/neck pain/stiffness, lethargy, irritability

Physical
• infants: toxic, hypothermia, bulging anterior fontanelle, respiratory distress, apnea, petechial/ purpuric rash, jaundice, omphalitis
• children: toxic, ↓ LOC, nuchal rigidity, Kernig's and Bruzinski's signs, focal neurologic findings, petechial/purpuric rash

Investigations
• blood work: CBC, electrolytes, Cr, BUN, glucose, culture with sensitivity
• lumbar puncture required for definitive diagnosis
  ▪ Gram stain, bacterial culture and sensitivity, WBC count and differential, RBC count, glucose, protein concentration (Table 24)
  ▪ acid-fast stain if suspect TB
  ▪ latex agglutination tests or PCR for specific bacteria if available (helpful if already treated with antibiotics)
  ▪ CSF cloudy in bacterial meningitis
  ▪ urinalysis and urine C&S in infants, Gram stain and culture of petechial/purpuric lesions

Signs of Meningismus
BONK on the head
Brudzinski’s sign
Opisthotonos*
Nuchal rigidity
Kernig’s sign

*Opisthotonos: rigid spasm of the body, with the back fully arched and the heels and head bent back

*lymphocytes predominate  Modified from Peds in Review 1993;14:11-18 and Ped Inf Dis J 1996;15:298-303

Management

- **supportive care**
  - preservation of adequate cerebral perfusion by maintaining normal BP and managing ↑ ICP
  - close monitoring of fluids, electrolytes, glucose, acid-base disturbances, coagulopathies

- **bacterial meningitis**
  - if suspected or cannot be excluded, commence empiric antibiotic therapy while awaiting cultures or if LP contraindicated or delayed
  - adjuvant dexamethasone BEFORE antibiotic for Hib meningitis; consider for those >6 wk with pneumococcal meningitis
  - isolation with appropriate infection control procedures until 24 h after culture-sensitive antibiotic therapy
  - fluid restrict if any concern for SIADH
  - hearing test
  - report to public health; prophylactic antibiotics for close contacts of Hib and *N. meningitidis* meningitis

- **viral meningitis**
  - mainly supportive (except for HSV)
  - acyclovir for HSV meningitis
  - report to public health

- **prophylaxis**: appropriate vaccinations significantly decrease incidence of bacterial meningitis (see Routine Immunization, P3)

Complications

- **mortality**: neonate 15-20%, children 4-8%; pneumococcus > meningococcus > HiB
- **acute**: SIADH, subdural effusion/empyema, brain abscess, disseminated infection (osteomyelitis, septic arthritis, abscess), shock/DIC
- **chronic**: hearing loss, neuromotor/cognitive delay, learning disabilities, neurological deficit, seizure disorder, hydrocephalus

Mumps

Definition

- acute, self-limited viral infection that is most commonly characterized by adenitis, and swelling of the parotid glands

Epidemiology

- incidence in Ontario has declined since introduction of two-dose MMR vaccination schedule
- average of 25 reported cases per year
- majority of reported cases in children between 5-10 yr of age

Etiology

- Mumps virus (RNA virus of the genus *Rubulavirus* in the *Paramyxoviridae* family)
- transmission via respiratory droplets, direct contact, fomites
- incubation period: 14-25 d
- infectivity period: 7 d pre-parotitis-5 d post-parotitis
- upper respiratory tract → lymph nodes → salivary glands, gonads, pancreas, meninges, kidney, heart, thyroid
History
• non-specific prodome of fever, headache, malaise, myalgias (especially neck pain)
• usually followed within 48 h by parotid swelling secondary to parotitis (bilateral, preauricular, ear pushed up and out)
• parotid gland is tender and pain worsened with spicy or sour foods
• one third of infections do not cause clinically apparent salivary gland swelling and may simply present as an URTI

Investigations
• clinical diagnosis, but may be confirmed with IgM positive serology within 4 wk of acute infection
  ▪ may also use PCR or viral cultures from oral secretions, urine, blood, and CSF
  ▪ blood work: CBC (leukopenia with relative lymphocytosis), serum amylase (elevated)

Management
• mainly supportive: analgesics, antipyretics, warm or cold packs to parotid may be soothing
• admit to hospital if serious complications (meningitis, pancreatitis)
• droplet precautions recommended until 5 d after onset of parotid swelling
• prophylaxis: routine vaccination (see Routine Immunization, P3)

Complications
• common: aseptic meningitis, orchitis/oophoritis
• less common: encephalitis, pancreatitis, thyroiditis, myocarditis, arthritis, glomerulonephritis, ocular complications, hearing impairment

Pertussis

Definition
• prolonged respiratory illness characterized by paroxysmal coughing and inspiratory "whoop"

Epidemiology
• ~10 million children <1 yr old affected worldwide, causes up to 400,000 deaths per year
• greatest incidence among children <1 yr (not fully immunized) and adolescents (waning immunity)

Etiology
• Bordetella pertussis: Gram negative pleomorphic rod
• highly contagious; transmitted via respiratory droplets released during intense coughing
• incubation period: 6-20 d; most contagious during catarrhal phase but may remain contagious for weeks after

History
• prodromal catarrhal stage
  ▪ lasts 1-7 d; URTI symptoms (coryza, mild cough, sneezing) with NO or LOW-GRADE fever
• paroxysmal stage
  ▪ lasts 4-6 wk; characterized by paroxysms of cough ("100 day cough"), sometimes followed by inspiratory whoop ("whooping cough")
  ▪ infants <6 mo may present with post-tussive apnea, whoop is often absent
  ▪ onset of attacks precipitated by yawning, sneezing, eating, physical exertion
  ▪ ± post-tussive emesis, may become cyanotic before whoop
• convalescent stage
  ▪ lasts 1-2 wk; characterized by occasional paroxysms of cough, but decreased frequency and severity
  ▪ non-infectious but cough may last up to 6 mo

Investigations
• nasopharyngeal (NP) specimen using aspirate or NP swab
  ▪ gold standard: culture using special media (Regan-Lowe agar)
  ▪ PCR to detect pertussis antigens
• blood work: CBC (lymphocytosis) and serology (antibodies against B. pertussis)

Management
• admit if paroxysms of cough are associated with cyanosis and/or apnea and give O₂
• supportive care
• antimicrobial therapy indicated if B. pertussis isolated, or symptoms present for <21 d
  ▪ use macrolide antibiotics (azithromycin, erythromycin or clarithromycin)
• droplet isolation until 5 d of treatment
  ▪ report to public health
• prophylaxis
  - macrolide antibiotics for all household contacts
  - prevention with vaccination in infants and children (Pentacel®), and booster in adolescents (Adacel®) (see Routine Immunization, P3)

Complications
• pressure related from paroxysms: subconjunctival hemorrhage, rectal prolapse, hernias, epistaxis
• respiratory: sinusitis, pneumonia, aspiration, atelectasis, pneumomediastinum, pneumothorax, alveolar rupture
• neurological: seizures (~3%), encephalopathy, intracranial hemorrhage
• mortality: ~0.3%; highest risk in infants <6 mo old

Pneumonia
• see P93

Periorbital (Preseptal) and Orbital Cellulitis
• see Ophthalmology, OP10
  - preseptal cellulitis ~3 times more common than orbital cellulitis
  - causative pathogens include: S. aureus, S. pyogenes, S. pneumonia, M. catarrhalis, H. influenzae (less common now due to vaccination)
  - key to management is distinguishing between preseptal and orbital cellulitis (which is an OCULAR and MEDICAL EMERGENCY)

Sexually Transmitted Infection
• see Family Medicine, FM46 and Gynecology, GY26

Sinusitis
• see Family Medicine, FM47
  - complication of ≤10% of URTIs in children
  - clinical diagnosis
  - diagnostic imaging is NOT required to confirm diagnosis in children
    - routine CT not recommended, but consider if suspect complications of sinusitis, persistent/recurrent disease, need for surgery
  - antibiotic therapy for all children (although nearly half resolve spontaneously within 4 wk)
  - complications: preseptal/orbital (cellulitis, orbital abscess, osteomyelitis, etc.), intracranial (meningitis, abscess, etc.), Pott's Puffy tumour

Urinary Tract Infection (UTI)

Definition
• infection of the urinary bladder (cystitis) and/or kidneys (pyelonephritis)

Epidemiology
• overall prevalence in infants and young children presenting with fever is 7%
  - <4-6 wk old: more common in boys
  - >1 yr old: females have two to four fold higher prevalence

Etiology
• majority (>95%) have a monomicrobial cause with E. coli identified as the causative agent most of the time (~70%)
• Gram-negative bacilli: E. coli, Klebsiella, Proteus, Enterobacter, Pseudomonas
• Gram-positive cocci: S. saprophyticus, Enterococcus

Risk Factors
• non-modifiable: female gender, Caucasian, previous UTIs, family history
• modifiable: urinary tract abnormalities (vesicoureteral reflux, neurogenic bladder, obstructive uropathy, posterior urethral valve), dysfunctional voiding, repeated bladder catheterization, uncircumcised males, labial adhesions, sexually active, constipation, toilet training
History

- infants and young child: often just fever or non-specific symptoms (poor feeding, irritability, FTT, jaundice if <28 d old, vomiting)
- older child: fever, urinary symptoms (dysuria, urgency, frequency, incontinence, hematuria), abdominal and/or flank pain

Physical

- infants and young child: toxic vs non-toxic, febrile, FTT, jaundice; look for external genitalia abnormalities (phimosis, labial adhesions) and lower back signs of occult myelodysplasia (e.g. hair tufts), which may be associated with neurogenic bladder
- older child: febrile, suprapubic and/or CVA tenderness, abdominal mass (enlarged bladder or kidney); may present with short stature, FTT or hypertension secondary to renal scarring from previously unrecognized or recurrent UTIs

Investigations

- sterile urine specimen
  - clean catch, catheterization or suprapubic aspiration
  - urinalysis (leukocyteesterase, nitrites, erythrocytes), microscopy (bacteria and leukocytes), culture and sensitivity
- diagnosis established if urinalysis suggests infection AND if ≥50,000 colony-forming units per mL of a uropathogen cultured

Management

- admit if: <2 mo old, urosepsis, persistent vomiting, inability to tolerate oral medication, moderate-severe dehydration, immunocompromised, complex urologic pathology, inadequate follow-up, failure to respond to outpatient therapy
- supportive care: maintenance of hydration and adequate pain control
- antibiotics
  - base on local antimicrobial susceptibility patterns
  - commence broad empiric therapy until results of urine culture and sensitivity known, and then tailor as appropriate
- neonates: IV ampicillin and gentamicin
- infants and older children: oral cephalexin if outpatient; IV ampicillin and gentamicin if inpatient
- duration 7-14 d
- imaging
  - renal and bladder U/S for all febrile infants with UTIs looking for anatomical abnormalities, hydronephrosis, abscess
  - voiding cystourethrogram (VCUG) not recommended after 1st febrile UTI unless U/S reveals hydronephrosis, obstructive uropathies or other signs suggestive of high-grade vesicoureteral reflux (VUR)
- follow-up: outpatients to return in 24-48 h if no clinical response and seek prompt medical evaluation for future febrile illnesses
- prophylaxis: generally not recommended unless higher grades of VUR

Complications

- long term morbidity: focal renal scarring develops in 8% of patients; long term significance unknown

Neonatology

Gestational Age (GA) and Size

Definitions

- classification by gestational age (GA)
  - preterm: <37 wk
  - term: 37-42 wk
  - post-term: >42 wk
- classification by birth weight
  - small for gestational age (SGA): 2 SD < mean weight for GA or <10th percentile
  - appropriate for gestational age (AGA): within 2 SD of mean weight for GA
  - large for gestational age (LGA): 2 SD > mean weight for GA or >90th percentile

### Routine Neonatal Care

1. erythromycin ointment: applied to both eyes for prophylaxis of ophthalmaeonatorum
2. vitamin K IM: prophylaxis against hemorrhagic disease of newborn
3. screening tests
   - in Ontario, newborn screening tests for
     - hearing loss
     - endocrine disorders (congenital adrenal hyperplasia, congenital hypothyroidism)
     - cystic fibrosis
     - hemoglobinopathies (HbSS, HbSc, etc.)
     - inborn errors of metabolism including galactosemia, biotinidase deficiency, fatty acid oxidation defects
4. if mother Rh negative: send cord blood for blood group and direct antiglobulin test
5. if mother hepatitis B surface antigen positive: HBcAg and start hepatitis B vaccine series

### Neonatal Resuscitation

- assess Apgar at 1 and 5 min
- if <7 at 5 min then reassess q5min, until >7
- do not wait to assign Apgar score before initiating resuscitation

### Table 27. Apgar Score

Initial Resuscitation

- anticipation: know maternal history, history of pregnancy, labour, and delivery
- steps to take for all infants (before ABCs)
  - warm (radiant heater, warm towels) and dry the newborn (remove wet towels)
  - position and clear airway ("sniffing" position)
  - stimulate infant: rub lower back gently or flick soles of feet EXCEPT if meconium present (in which case tracheal suction first)
  - assess breathing and heart rate

Airway

- if meconium is present and
  - baby is vigorous (strong respiratory effort, good muscle tone, HR >100): no further reuscitative interventions required
  - baby is not vigorous: intubate and suction trachea while monitoring vital signs. If prolonged or unsuccessful intubation, attempt bag mask ventilation
- if no meconium and suction required, suction mouth first and then nose

Breathing

- if HR <100 or apnoeic, apply positive pressure ventilation (PPV)
  - PPV at rate of 40-60/min with enough pressure to see visible chest expansion and note increase in HR
- if PPV not effective (no increase in HR, no chest rise), incorporate MR SOPA corrective actions

Circulation

- if HR <60 after 30 s of effective ventilation, start chest compressions ("60 or less, compress")
  - should provide 100% oxygen as soon as chest compressions are required
- chest compressions at lower 1/3 of the sternum and 1/3 of the AP depth at a rate of 120 events per min (3 compressions:1 ventilation = 90 compressions/min:30 breaths/min)

Approach to the Depressed Newborn

- a depressed newborn lacks one or more of the following characteristics of a normal newborn
  - pulse >100 bpm
  - cries when stimulated
  - actively moves all extremities
  - has a good strong cry
- approximately 10% of newborn babies require assistance with breathing after delivery

Diagnosis
- vital signs
- detailed maternal history
  - include prenatal care, illnesses, use of drugs, labour, previous high risk pregnancies, infections during pregnancy, current infections, duration of ruptured membranes, blood type and Rh status, amniotic fluid status, gestational age, meconium, Apgar scores
- clinical findings (observe for signs of respiratory distress: cyanosis, tachypnea, retractions, grunting, temperature instability)
- laboratory results (CBC, ABG, blood type, glucose)
- transillumination
- CXR

Management
- ABCs
- intubation and suction if meconium present
- apply tactile stimulation if no meconium
- provide PPV if apneic or HR <100 bpm
- monitor oxygen saturation and heart rate (if HR <60 bpm, start chest compressions)
- provide ventilatory support and treat the underlying cause

Common Conditions of Neonates

Apnea

Definition
- “periodic breathing”: normal respiratory pattern seen in newborns in which periods of rapid respiration are alternated with pauses lasting 5-10 s
- “apnea”: absence of respiratory gas flow for >15 s (or less if associated with bradycardia or desaturation) – 3 types:
  - central: no chest wall movement, no signs of obstruction
  - obstructive: chest wall movement continues against obstructed upper airway, no airflow
  - mixed: combination of central and obstructive apnea

Differential Diagnosis
- in term infants, apnea requires full work-up as it can be associated with sepsis
- other causes:
  - CNS
    - apnea of prematurity (<34 wk): combination of CNS immaturity and obstructive apnea; resolves by 36 wk GA; diagnosis of exclusion
    - seizures
    - intracranial hemorrhage (ICH)
    - hypoxic injury
  - infectious: sepsis, meningitis, necrotizing enterocolitis (NEC)
  - GI: gastroesophageal reflux disease (GERD), aspiration with feeding
  - metabolic: hypoglycemia, hyponatremia, hypocalcemia, IEM
  - cardiovascular: anemia, hypovolemia, PDA, heart failure
  - drugs: morphine
Management
• O2, ventilatory support, maintain normal blood gases
• tactile stimulation
• correct underlying cause
• medications: methylxanthines (caffeine) stimulate the CNS and diaphragm and are used for apnea of prematurity (not in term infants)

**Bleeding Disorders in Neonates**

**Clinical Presentation**
• oozing from the umbilical stump, excessive bleeding from peripheral venipuncture/heel stick sites/IV sites, large caput succedaneum, cephalohematomas (in absence of significant birth trauma), subgaleal haemorrhage and prolonged bleeding following circumcision

**Approach to Bleeding Disorders in Neonates**
• 4 major categories

1. increased platelet destruction:
   • maternal ITP, SLE
   • neonatal alloimmune thrombocytopenia (NAIT)
   • infection
   • DIC
   • drugs
   • extensive localized thrombosis

2. decreased platelet production/function:
   • bone marrow replacement
   • pancytopenia
   • Fanconi anemia
   • Trisomy 13 and 18

3. metabolic:
   • congenital thyrotoxicosis
   • inborn error of metabolism

4. coagulation factor deficiencies (see Hematology, H29):
   • hemophilia A
   • hemophilia B
   • hemorrhagic disease of the newborn

**NEONATAL ALLOIMMUNE THROMBOCYTOPENIA (NAIT)**

**Epidemiology**
• 1 per 4000-5000 live births

**Pathophysiology**
• platelet equivalent of Rh disease of the newborn
• occurs when mother is negative for human platelet antigen (HPA) and fetus is positive
• development of maternal IgG antibodies against HPA antigens on fetal platelets

**Clinical Presentation**
• petechiae, purpura, thrombocytopenia in otherwise healthy neonate
• severe NAIT can lead to intracranial bleeding

**Diagnosis**
• maternal and paternal platelet typing and identification of platelet alloantibodies

**Treatment**
• IVIG to mother prenatally starts in second trimester ± steroids ± fetal platelet transfusions
• treat neonate with IVIG
• if transfusion required should be with washed maternal platelets or donor HPA negative platelets

**AUTOIMMUNE THROMBOCYTOPENIA**

**Pathophysiology**
• caused by antiplatelet antibodies from maternal ITP or SLE
• passive transfer of antibodies across placenta

**Clinical Presentation**
• similar presentation to NAIT, but thrombocytopenia usually less severe

**Treatment**
• steroids to mother for 10-14 d prior to delivery or IVIG to mother before delivery
• IVIG infant after delivery (usually if platelets <60,000)
• transfusion of infant with maternal/donor platelets only in severe cases, as antibodies will destroy transfused platelets
HEMORRHAGIC DISEASE OF THE NEWBORN
- caused by vitamin K deficiency
- factors II, VII, IX, X are vitamin K-dependent, therefore both PT and PTT are abnormal

Etiology and Clinical Presentation
- neonates at risk of vitamin K deficiency if:
  - vitamin K poorly transferred across the placenta
  - maternal use of anticonvulsants
  - insufficient bacterial colonization of colon at birth to synthesize vitamin K
  - dietary intake of vitamin K inadequate in breastfed infants

Prevention
- vitamin K IM administration at birth to all newborns

Bronchopulmonary Dysplasia (BPD)

Definition
- also known as chronic lung disease (CLD)
- clinically defined as O\textsubscript{2} requirement for >28 d plus persistent need for oxygen and/or ventilatory support at 36 wk corrected GA
- damage to developing lungs with prolonged intubation/ventilation

Investigations
- CXR findings may demonstrate decreased lung volumes, areas of atelectasis and hyperinflation

Treatment
- no good treatments
- gradual wean from ventilator, optimize nutrition
- dexamethasone may help decrease inflammation and encourage weaning, but use of dexamethasone is associated with increased risk of adverse neurodevelopmental outcomes

Prognosis
- chronic respiratory failure may lead to pulmonary hypertension, poor growth, and right-sided heart failure
- patients with BPD may continue to have significant impairment and deterioration in lung function late into adolescence
- some lung abnormalities may persist into adulthood including airway obstruction, airway hyper-reactivity, and emphysema
- associated with increased risk of adverse neurodevelopmental outcomes

Cyanosis

Figure 12. Approach to neonatal cyanosis
Management

- **ABGs**
  - elevated CO₂ suggests respiratory cause
  - hyperoxia test (to distinguish between cardiac and respiratory causes of cyanosis): get baseline PaO₂ in room air, then PaO₂ on 100% O₂ for 10-15 min
    - PaO₂ <150 mmHg: suggests cyanotic congenital heart disease or possible persistent newborn pulmonary hypertension (PPHN) (see Pediatric Cardiology, P16)
    - PaO₂ >150 mmHg: suggests cyanosis likely due to respiratory or non-cardiac cause
- **CXR**: look for respiratory abnormalities (respiratory tract malformations, evidence of shunting, pulmonary infiltrates) and cardiac abnormalities (cardiomegaly, abnormalities of the great vessels)

### Diaphragmatic Hernia

**Definition**
- developmental defect of the diaphragm with herniation of abdominal organs into thorax
- associated with pulmonary hypoplasia and PPHN

**Clinical Presentation**
- respiratory distress, cyanosis
- scaphoid abdomen and barrel-shaped chest
- affected side dull to percussion and breath sounds absent, may hear bowel sounds instead
- heart sounds shifted to contralateral side
- asymmetric chest movements, trachea deviated away from affected side
- may present outside of neonatal period
- often associated with other anomalies (cardiovascular, CNS, chromosomal abnormalities)
- **CXR**: bowel loops in thorax (usually left side), displaced mediastinum

**Treatment**
- immediate intubation required at birth: DO NOT bag mask ventilate because air will enter stomach and further compress lungs
- place large bore orogastric tube to decompress bowel
- initial stabilization and management of pulmonary hypoplasia and PPHN, hemodynamic support and surgery when stable

### Hypoglycemia

**Definition**
- glucose <2.6 mmol/L (40 mg/dL)

**Etiology**
- decreased carbohydrate stores (premature, IUGR)
- infant of a diabetic mother (IDM): maternal hyperglycemia → fetal hyperglycemia and hyperinsulinism → hypoglycemia in the newborn infant because of high insulin levels
- sepsis
- hyperinsulinism due to islet cell hyperplasia (e.g. Beckwith-Wiedemann syndrome)
- panhypopituitarism
- inborn errors of metabolism: fatty acid oxidation defects, galactosemia

**Clinical Findings**
- signs often non-specific and subtle: lethargy, poor feeding, irritability, tremors, apnea, cyanosis, seizures

**Management**
- identify and monitor infants at risk (pre-feed blood glucose checks)
- begin oral feeds as soon as possible after birth and ensure regular feeds
- if significant and/or symptomatic hypoglycemia, provide glucose IV and titrate according to blood sugar levels
- if persistent hypoglycemia or no predisposing cause for hypoglycemia, send “critical bloodwork” during an episode of hypoglycemia:
  - insulin
  - cortisol
  - growth hormone (GH)
  - β-hydroxybutyrate
  - lactate
  - ammonia
  - free fatty acids (FFAs)
  - ABG
- hyperinsulinism managed with glucagon and/or diazoxide, consultation with pediatric endocrinologist

---

**Carboxyhemoglobinemia** (secondary to carbon monoxide poisoning) results in impaired binding of oxygen to hemoglobin but does not discolour the blood. Therefore it may not register on pulse-oximetry and cyanosis may not be evident clinically.

**Methemoglobinemia** pulse oximetry typically reads higher than the true level of oxyhemoglobin. Methemoglobin alters the absorption of red light at the two wavelengths that pulse oximetry uses to predict oxygen saturation.
**Intraventricular Hemorrhage (IVH)**

**Definition**
- hemorrhage originating in the periventricular subependymal germinal matrix (GM)

**Epidemiology**
- incidence and severity inversely proportional to gestational age
- 50% of IVH occurs within 8 h of birth; 90% occurs by day 3

**Risk Factors**
- prematurity (<32 wk), BW <1500 g, need for vigorous resuscitation at birth, pneumothorax, ventilated preterm infants, hemodynamic instability, RDS, coagulopathy

**Clinical Presentation**
- many infants with IVH are asymptomatic
- subtle signs: apnea, bradycardia, changes in tone or activity, altered level of consciousness
- catastrophic presentation: bulging fontanelle, sudden drop in hematocrit, acidosis, seizures, hypotension

**Classification**
- Papile classification
- parenchymal hemorrhage may also occur in the absence of intraventricular hemorrhage
- routine head ultrasound screening of all preterm infants <32 wk or <1500 g gestation throughout NICU stay

**Management of Acute Hemorrhage**
- supportive care to maintain blood volume and acid-base status
- avoid fluctuations in blood pressure and cerebral blood flow
- follow-up with serial imaging

**Prognosis**
- outcome depends on grade of IVH
- short-term sequelae for severe IVH: mortality, extension of bleed, posthemorrhagic hydrocephalus (PHH), posthemorrhagic infarction, cyst formation
- possible long-term major neurological sequelae: cerebral palsy, cognitive deficits, motor deficits, visual and hearing impairment
- grades I and II hemorrhages have a relatively favourable prognosis
- greatest morbidity and mortality is seen with Grade IV hemorrhage and PHH requiring ventriculoperitoneal shunt placement

---

**Jaundice**

**Clinical Presentation**
- jaundice is visible at serum bilirubin levels of 85-120 µmol/L
- look at sclera, tip of nose in natural light
- jaundice more severe/prolonged (due to increased retention of bilirubin in the circulation) with:
  - prematurity, acidosis, hypoalbuminemia, dehydration

---

![Figure 13. Approach to neonatal hyperbilirubinemia](image-url)
**PHYSIOLOGIC JAUNDICE**

**Epidemiology**
- term infants: onset 2-3 d of life, resolution by 7 d of life
- premature infants: higher peak and longer duration

**Pathophysiology**
- increased hematocrit and decreased RBC lifespan
- immature glucuronyl transferase enzyme system (slow conjugation of bilirubin)
- increased enterohepatic circulation

**Table 30. Risk Factors for Jaundice**

</tbody>
</table>

**Breastfeeding Jaundice**
- common; due to a lack of milk production → dehydration → exaggerated physiologic jaundice

**Breast Milk Jaundice**
- 1 per 200 breastfed infants
- glucuronyl transferase inhibitor found in breast milk
- onset 7 d of life, peak at 2-3 wk of life, usually resolved by 6 wk

**PATHOLOGIC JAUNDICE**
- must be investigated if:
  - jaundice at <24 h of age
  - serum unconjugated bilirubin rises rapidly or is excessive for patient's age and weight
  - conjugated hyperbilirubinemia
  - persistent jaundice lasting beyond 1-2 wk of age
- investigations
  - unconjugated hyperbilirubinemia:
    - hemolytic work-up: CBC, reticulocyte count, blood group (mother and infant), peripheral blood smear, Coombs test, bilirubin (conjugated, unconjugated)
    - if baby is unwell or has fever: septic work-up (CBC and differential, blood and urine cultures ± LP, CXR)
    - other: G6PD screen (in males), TSH
  - conjugated hyperbilirubinemia: consider liver enzymes (AST, ALT), coagulation studies (PT, PTT), serum albumin, ammonia, TSH, TORCH screen, septic work-up, galactosemia screen (erythrocyte galactose-1-phosphate uridyltransferase levels), metabolic screen, abdominal U/S, HIDA scan, sweat chloride

**TREATMENT OF UNCONJUGATED HYPERBILIRUBINEMIA**
- to prevent kernicterus (see P75)
- breastfeeding does not need to be discontinued, ensure adequate feeds and hydration
- lactation consultant support, mother to pump after feeds
- treat underlying causes (e.g. sepsis)
- phototherapy
  - insoluble unconjugated bilirubin is converted to excretable form via photoisomerization
  - serum bilirubin should be monitored during and immediately after therapy (risk of rebound because photoisomerization reversible when phototherapy discontinued)
contraindicated in conjugated hyperbilirubinemia: results in “bronzed” baby
side effects: skin rash, diarrhea, eye damage
use published guidelines for initiation of phototherapy
exchange transfusion
indications: high bilirubin levels as per published graphs based on age, weeks gestation
most commonly performed for hemolytic disease and G6PD deficiency

KERNICTERUS

Etiology
- unconjugated bilirubin concentrations exceed albumin binding capacity and bilirubin is deposited in the brain resulting in permanent damage (typically basal ganglia or brainstem)
- incidence increases as serum bilirubin levels increase above 340 µmol/L (19.8 mg/dL)
- can occur at lower levels in presence of sepsis, meningitis, hemolysis, hypoxia, acidosis, hypothermia, hypoglycemia and prematurity

Clinical Presentation
- up to 15% of infants have no obvious neurologic symptoms
- early stage: lethargy, hypotonia, poor feeding, emesis
- mid stage: hypertonia, high pitched cry, opisthotonic posturing (back arching), bulging fontanelle, seizures, pulmonary hemorrhage
- late stage (first year and beyond)
  - hypotonia, delayed motor skills, extrapyramidal abnormalities (choreoathetoid cerebral palsy), gaze palsy, mitral regurgitation, sensorineural hearing loss

Prevention
- exchange transfusion

Complications
- sensorineural deafness, choreoathetoid cerebral palsy (CP), gaze palsy, mental retardation

BILIARY ATRESIA

Definition
- atresia of the extrahepatic bile ducts which leads to cholestasis and increased conjugated bilirubin after the first week of life

Epidemiology
- incidence: 1:10,000-15,000 live births

Clinical Presentation
- dark urine, pale stool, jaundice (persisting for >2 wk), abdominal distension, hepatomegaly

Diagnosis
- conjugated hyperbilirubinemia, abdominal ultrasound
- HIDA scan
- liver biopsy

Treatment
- surgical drainage procedure
- hepatopportoenterostomy (Kasai procedure; most successful if <8 wk of age)
- usually requires liver transplantation
- vitamins A, D, E, and K; diet should be enriched with medium-chain triglycerides to ensure adequate fat ingestion

Necrotizing Enterocolitis (NEC)

Definition
- intestinal inflammation associated with focal or diffuse ulceration and necrosis
- primarily affecting terminal ileum and colon

Epidemiology
- affects 1-5% of preterm newborns admitted to NICU

Pathophysiology
- postulated mechanism of bowel ischemia: mucosal damage and enteral feeding → bacterial growth → bowel necrosis/gangrene/perforation
Risk Factors
- prematurity (immature defenses)
- asphyxia, shock (poor bowel perfusion)
- hyperosmolar feeds
- enteral feeding with formula (breast milk can be protective)
- sepsis

Clinical Presentation
- distended abdomen
- increased amount of gastric aspirate/vomit with bile staining
- frank or occult blood in stool
- feeding intolerance
- diminished bowel sounds
- signs of bowel perforation (sepsis, shock, peritonitis, DIC)

Investigations
- AXR: pneumonitis intestinalis (intramural air is a hallmark of NEC), free air, fixed loops, ileus, thickened bowel wall, portal venous gas
- CBC, ABG, lactate, blood culture, electrolytes
- high or low WBC, low platelets, hyponatremia, acidosis, hypoxia, hypercapnea

Treatment
- NPO (7-10 d), vigorous IV fluid resuscitation, decompression with NG tube, supportive therapy
- TPN
- antibiotics (usually ampicillin, gentamicin ± metronidazole if risk of perforation x 7-10 d)
- serial AXRs detect early perforation
- peritoneal drain/surgery if perforation
- surgical resection of necrotic bowel and surgery for complications (e.g. perforation, strictures)

Persistent Pulmonary Hypertension of the Newborn (PPHN)

Epidemiology
- incidence 1.9 per 1000 live births

Clinical Presentation
- usually presents within 12 h of birth with severe hypoxemia/cyanosis; may have only mild respiratory distress

Pathophysiology
- persistence of fetal circulation as a result of persistent elevation of pulmonary vascular resistance
- R → L shunt through PDA, foramen ovale → decreased pulmonary blood flow and hypoxemia → further pulmonary vasoconstriction

Risk Factors
- secondary PPHN: asphyxia, meconium aspiration syndrome (MAS), respiratory distress syndrome (RDS), sepsis, pneumonia, structural abnormalities (e.g. diaphragmatic hernia, pulmonary hypoplasia)
- primary PPHN occurs in absence of risk factors

Investigations
- measure pre- and post-ductal oxygen levels
- ECHO reveals increased pulmonary arterial pressure and a R → L shunt across PDA and PFO; also used to rule out other cardiac defects

Treatment
- maintain good oxygenation (SaO₂ >95%) in at-risk infants
- O₂ given early and tapered slowly, minimize stress and metabolic demands, maintain normal blood gases, circulatory support
- mechanical ventilation, high frequency oscillation (HFO)
- nitric oxide
- extracorporeal membrane oxygenation (ECMO) used in some centres when other therapy fails

Respiratory Distress in the Newborn

Clinical Presentation
- tachypnea: RR >60/min; tachycardia: HR >160/min
- grunting, subcostal/intercostal indrawing, nasal flaring
- dusky appearance, central cyanosis
- decreased air entry, crackles on auscultation
Differential Diagnosis of Respiratory Distress
- pulmonary
  - respiratory distress syndrome (RDS)
  - transient tachypnea of the newborn (TTN)
  - meconium aspiration syndrome (MAS)
  - pleural effusions, pneumothorax
  - congenital lung malformations
- infectious
  - sepsis, pneumonia
- cardiac
  - congenital heart disease (cyanotic, acyanotic)
  - persistent pulmonary hypertension of the newborn (PPHN)
- hematologic
  - blood loss, polycythemia
- anatomic
  - tracheoesophageal fistula
  - congenital diaphragmatic hernia
  - upper airway obstruction (see Otolaryngology, OT44)
    - choanal atresia
    - Pierre-Robin sequence (retrognathia ± micrognathia, cleft palate, glossoptosis)
    - laryngeal (malacia)
    - tracheal (malacia, vascular ring)
    - mucous plug
    - cleft palate
- metabolic
  - hypoglycemia
  - inborn errors of metabolism (amino acidemia, organic acidemia, urea cycle disturbance, galactosemia, 1st lactic acidosis)
- neurologic
  - CNS damage (trauma, hemorrhage)
  - drug withdrawal syndromes

Investigations
- CXR, ABG
- CBC, blood cultures, blood glucose
- ECHO, ECG if indicated

PNEUMONIA

- see Pediatric Respirology, P93
- consider in infants with prolonged or premature rupture of membranes (PROM), maternal fever, or if mother is GBS positive
- suspect if infant exhibits respiratory distress, temperature instability, or WBC is low, elevated or left-shifted
- symptoms may be non-specific
- CXR: hazy lung and/or distinct infiltrates (may be difficult to differentiate from RDS)

Retinopathy of Prematurity (ROP)

- see Ophthalmology, OP41

</table>

Signs of Sepsis
- no reliable absolute indicator of occult bacteremia in infants <3 mo, most specific result has been WBC <5
- temperature instability (hypo/hyperthermia)
- respiratory distress, cyanosis, apnea
- tachycardia/bradycardia
- lethargy, irritability
- poor feeding, vomiting, abdominal distension, diarrhea
- hypotonia, seizures, lethargy
- jaundice, hepatomegaly, petechiae, purpura

Nephrology

Approach to Infant/Child with Dehydration

Etiology
- decreased intake: poor oral intake during acute illness, breastfeeding difficulties, eating disorders
- increased losses, common sites include:
  - GI: diarrhea, vomiting, bleeding
  - skin/mucous membranes: fever, burns, hemorrhage, stomatitis
  - urinary: osmolar diuresis (e.g. hyperglycemia, DKA), diuretic therapy, diabetes insipidus, post-obstructive/post ATN recovery diuresis
  - respiratory: tachypnea, bronchitis, pneumonia

Management
- if suspect dehydration based on history (acute illness, number of wet diapers, lethargy, changes in mental status, thirst, etc.), you must:

1) Determine degree of extracellular volume contraction

Table 35. Assessment of Degree of Extracellular Volume Contraction based on Physical Examination

• initial investigations should include blood work for ALL patients looking at:
  ▪ electrolyte disturbances (Na⁺, K⁺, Cl⁻) + glucose
  ▪ acid-base disturbances (blood pH, pCO₂, HCO₃⁻)
  ▪ impaired renal function (creatinine, BUN)

3) Determine if the child requires oral or intravenous rehydration
• dehydrated child must receive adequate fluid management, including replacement of ongoing losses and providing maintenance fluids
• initial management using oral rehydration therapy (ORT) advantages: ↓ cost, no IV needed, ↓ incidence if iatrogenic hyper/hyponatremia, parental involvement
• indications for intravenous rehydration therapy:
  ▪ severe dehydration, which requires close monitoring and frequent assessment of electrolytes
  ▪ inability to tolerate ORT (e.g. vomiting, alteration in mental status, ileus, monosaccharide malabsorption, etc.)
  ▪ inability to provide ORT
  ▪ failure of ORT in providing adequate rehydration (e.g. persistent diarrhea or vomiting)

4) Return the child to a normal volume and electrolyte status by replacing current deficits and ongoing losses

Figure 15. Algorithm for deficit replacement and replacement of ongoing losses in the dehydrated child
5) Provide the appropriate fluid and electrolyte maintenance daily requirements (Tables 36 and 37)

Table 37. Maintenance Fluid Requirements

<table>
<thead>

</tbody>
</table>

- Types of fluids used:
  - normal saline (NS), Ringer's lactate (RL), half-normal saline (0.45% NaCl), 0.2% NS (for neonates only), D5W, and D10W (for neonates only), add potassium chloride (if hypokalemic)
- Common IV fluid combinations used in pediatrics:
  - first month of life: D5W/0.2 NS + 20 mEq KCl/L (only add KCl if voiding well)
  - children: D5W/NS + 20 mEq KCl/L or D5W/0.45 NS + 20 mEq KCl/L
  - NS: as bolus to restore circulation in dehydrated children (remains almost entirely distributed in intravascular space)
- Correction of Fluid and Electrolyte Deficits
  - if serum [Na+] <138-144 mmol/L, use NS or RL
  - if serum [Na+] 145-154 mmol/L, IV fluid sodium concentration should approximate 0.45 NS
  - if serum [Na+] >154 mmol/L, risk of cerebral edema with rapid rehydration of hypotonic solutions (i.e. NS) therefore replace fluid slowly with close monitoring.

6) Continue to monitor fluid and electrolyte status

- accurate monitoring of daily fluid intake (oral and IV) and ongoing losses (urine output, diarrhea, emesis, drains)
- if child receiving >50% of maintenance fluids through IV, serum electrolyte values should be monitored DAILY and adjusted accordingly
- avoid iatrogenic hyper/hyponatremia, keep the possibility of SIADH in mind

**Hemolytic Uremic Syndrome (HUS)**

Definition

- simultaneous occurrence of the triad of 1) non-immune microangiopathic hemolytic anemia, 2) thrombocytopenia and 3) acute renal injury

Epidemiology

- annual incidence of 1-2 per 100,000 in Canada
- most common cause of acute renal failure in children
Etiology
- diarrhea positive HUS: 90% of pediatric HUS from E. coli O157:H7 shiga toxin or verotoxin
- diarrhea negative HUS: other bacteria, viruses, familial, drugs

Pathophysiology
- toxin binds, invades and destroys colonic epithelial cells, causing bloody diarrhea
- toxin enters the systemic circulation, attaches and injures endothelial cells (especially in kidney) causing a release of endothelial products (e.g. von Willebrand factor, platelet aggregating factor)
- form platelet/fibrin thrombi in multiple organ systems (e.g. kidney, pancreas, brain, etc.) resulting in thrombocytopenia
- RBCs are forced through occluded vessels resulting in fragmented RBCs (schistocytes) that are removed by the reticuloendothelial system (hemolytic anemia)

History and Physical
- initial presentation of abdominal pain and diarrhea, followed by bloody diarrhea
- within 5–7 d begins to show signs of anemia, thrombocytopenia and renal insufficiency
- history: weakness, lethargy, oliguria
- physical exam: pallor, jaundice (hemolysis), edema, petechiae, hypertension

Investigations
- CBC (anemia, thrombocytopenia), blood smear (schistocytes), electrolytes, renal function, urinalysis (microscopic hematuria), stool cultures and verotoxin/shigella toxin assay

Management
- mainly supportive: nutrition, hydration, ventilation (if necessary), blood transfusion for symptomatic anemia
- monitor electrolytes and renal function: dialysis if electrolyte abnormality cannot be corrected, fluid overload, or uremia
- steroids are NOT helpful
- antibiotics are contraindicated because death of bacteria leads to increased toxin release and worse clinical course

Prognosis
- 5-10% mortality, 10-30% renal damage

Nephritic Syndrome

Definition
- acute or chronic syndrome affecting the kidney, characterized by glomerular injury and inflammation, and defined by hematuria (>5 RBCs per high-powered microscope field) and the presence of dysmorphic RBCs and RBC casts on urinalysis
- often accompanied by at least one of proteinuria (<50 mg/kg/d), edema, hypertension, azotemia, and oliguria

Epidemiology
- highest incidence in children aged 5-15 yr old

Etiology
- humoral immune response to a variety of etiologic agents → immunoglobin deposition → complement activation, leukocyte recruitment, release of growth factors/cytokines → glomerular inflammation and injury → porous podocytes → hematuria + RBC casts ± proteinuria
- hypertension secondary to fluid retention and increased renin secretion by ischemic kidneys
- primary (idiopathic) versus secondary (to a systemic disease), low complement levels versus normal complement levels (Table 39)

Table 39. Major Causes of Nephritic Syndrome

<table>
<thead>
<tr>

<td>Abscess or shunt nephritis</td>
<td>Granulomatosis with polyangitis (GPA)</td>
</tr>
<tr>
<td></td>
<td>Cryoglobulinemia</td>
<td>Goodpasture’s syndrome</td>
</tr>
</tbody>
</table>
Risk Factors
- recent streptococcal pharyngitis or skin infection, systemic illnesses (see Etiology of Nephritic Syndrome, P82)

History and Physical
- often asymptomatic; some overlap in clinical findings for nephritic and nephrotic syndrome
- gross hematuria, mild-moderate edema, oliguria
- signs and symptoms suggestive of underlying systemic causes (e.g. fever, arthralgias, rash, dyspnea, pulmonary hemorrhage)

Investigations
- urine
  - dipstick (hematuria, 0 to 2+ proteinuria) and microscopy (>5 RBCs per high-powered microscope field, acanthocytes, RBC casts)
  - first morning urine protein/creatinine ratio (<200 mg/mmol)
- blood work
  - impaired renal function (↑ Cr and BUN) resulting in ↓ pH and electrolyte abnormalities (hyperkalemia, hyperphosphatemia, hypocalcemia)
  - mild anemia on CBC (secondary to hematuria)
  - hypoalbuminemia (secondary to proteinuria)
  - appropriate investigations to determine etiology: C3/C4 levels, serologic testing for recent streptococcal infection (ASOT, anti-hyaluronidase, anti-streptokinase, anti-NAD, anti-DNase B), ANA, anti-DNA antibodies, ANCA, serum IgA levels, anti-GBM antibodies
- renal biopsy
  - should be considered only in presence of: acute renal failure, no evidence of streptococcal infection, normal C3/C4

Management
- treat underlying cause
- symptomatic
  - renal insufficiency: supportive (dialysis if necessary), proper hydration
  - hypertension: salt and fluid restriction (but not at expense of renal function), ACE inhibitors or ARBs for chronic persistent HTN (not acute cases since ACE inhibitors or ARBs may decrease GFR further)
  - edema: salt and fluid restriction, possibly diuretics (avoid if significant intravascular depletion)
  - corticosteroids if indicated: IgA nephropathy, lupus nephritis, etc.

Prognosis
- dependent on underlying etiology
- complications include hypertension, heart failure, pulmonary edema, chronic kidney injury (requiring renal transplant)

Nephrotic Syndrome

Definition
- clinical syndrome affecting the kidney, characterized by significant proteinuria, peripheral edema, hypoalbuminemia, and hyperlipidemia

Epidemiology
- highest incidence in children of 2 to 6 yr old, M>F

Etiology
- primary nephrotic syndrome; nephrotic syndrome (NS) in the absence of systemic disease (most common cause in pediatrics)
  - glomerular inflammation ABSENT on renal biopsy: minimal change disease (>90% of all NS), focal segmental glomerular sclerosis (FSGS)
  - glomerular inflammation PRESENT on renal biopsy: membranoproliferative glomerulonephritis, IgA nephropathy, other minor causes
- secondary nephrotic syndrome: NS associated with systemic disease or due to another process causing glomerular injury (very rare in pediatrics)
  - autoimmune: SLE, diabetes mellitus, rheumatoid arthritis, etc.
  - genetic: sickle cell disease, Alport syndrome, etc.
  - infections: HBV/HCV, post-streptococcal, infective endocarditis, HUS, HIV, etc.
  - malignancies: leukemia, lymphoma, etc.
  - medications: captopril, penicillamine, NSAIDs, anticonvulsants, etc.
  - vasculitides: Henoch-Schönlein, GPA, etc.
- congenital nephrotic syndrome: congenital nephropathy of the Finnish type, Denys-Drash syndrome, etc.
**Risk Factors**
- family history, certain systemic illnesses and medications (as per Etiology, P83)

**History and Physical**
- non-specific (e.g. irritability, malaise, fatigue, anorexia, diarrhea)
- edema
  - often first sign; detectable when fluid retention exceeds 3 to 5 percent of body weight
  - starts periorbital and often pretibial → edematous areas are white, soft, and pitting
  - gravity dependent: periorbital edema ↓ and pretibial edema ↑ over the day
  - anasarca may develop (i.e. marked periorbital and peripheral edema, ascites, pleural effusions, scrotal/labial edema)
- decrease in effective circulating volume (e.g. tachycardia, hypertension, oliguria, etc.)
- foamy urine is a possible sign of proteinuria

**Investigations**
- urine
  - urine dipstick (3 to 4+ proteinuria, microscopic hematuria) and microscopy (oval fat bodies, hyaline casts)
  - first morning urine protein/creatinine ratio (>200 mg/mmol)
- blood work
  - diagnostic: hypoalbuminemia (<25 g/L), hyperlipidemia/hypercholesterolemia (total cholesterol >5 mmol/L)
  - secondary: electrolytes (hypocalcemia, hyperkalemia, hyponatremia), renal function (↑ BUN and Cr), coagulation profile (↑ PTT)
  - appropriate investigations to rule out secondary causes of NS: CBC, blood smear, C3/C4, ANA, HBV/HCV titers, ASOT, HIV serology, etc.
- consider renal biopsy if:
  - HTN (↑ risk of FSGS), gross hematuria, renal function, low serum C3/C4
  - no response to steroids after 4 wk of therapy
  - frequent relapses (>2 relapses in 6 mo)
  - presentation before first year of life (high likelihood of congenital nephrotic syndrome)
  - presentation ≥12 yr (rule out more serious renal pathology than minimal change disease)

**Management**
- minimal change disease: oral prednisone 2 mg/kg/d (or equivalent) for up to 12 wk → varicella status should be known before starting
- consider cytotoxic agents, immunomodulators or high-dose pulse corticosteroid if steroid resistant
- symptomatic
  - edema: salt and fluid restriction, possibly diuretic (avoid if significant intravascular depletion); furosemide + albumin for anasarca
  - hyperlipidemia: generally resolves with remission; limit dietary fat intake; consider statin therapy if persistently nephrotic
  - hypoalbuminemia: IV albumin and lasix not routinely given; consider if refractory edema
  - abnormal BP: control BP; fluid resuscitation if severe intravascular depletion; ACE inhibitors or ARBs for persistent HTN
- diet: NAS (no added salt) diet; monitor caloric intake and supplement with Ca²⁺ and Vit D if on corticosteroids
- daily weights and blood pressure to assess therapeutic progress
- secondary infections:
  - treat with appropriate antimicrobials; antibiotic prophylaxis not recommended
  - pneumococcal vaccine at diagnosis and varicella vaccine after remission; varicella Ig + acyclovir if exposed while on corticosteroids
- secondary hypercoagulability: mobilize, avoid hemoconcentration due to hypovolemia, prompt sepsis treatment; heparin if thrombi occur

**Prognosis**
- generally good: 80% of children responsive to corticosteroids
- up to 2/3 experience relapse, often multiple times; sustained remission with normal kidney function usually by adolescence
- complications: ↑ risk of infections (spontaneous peritonitis, cellulitis, sepsis); hypercoagulability due to decreased intravascular volume and antithrombin III depletion (pulmonary embolism, renal vein thrombosis; intravascular depletion-hypotension, shock, renal failure; side effects of drugs)
Hypertension in Childhood

Definition
- hypertension: systolic and/or diastolic blood pressure (BP) that is ≥95th percentile for sex, age and height (Table 40) on ≥3 occasions
- prehypertension: systolic and/or diastolic BP ≥90th percentile but <95th percentile OR BP ≥120/80 irrespective of age, gender and height

Adapted from Update on the 1987 Task Force Report on High Blood Pressure in Children and Adolescents working group report from the National High Blood Pressure Education Program

Epidemiology
- increasing prevalence of both hypertension and prehypertension over the last 25+ yr
- prevalence: 3-5% for hypertension, 7-10% for prehypertension; M>F

Etiology
- primary HTN
  - diagnosis of exclusion
  - most common in older children (≥10 yr), especially if positive family history, overweight and only mild hypertension
  - responsible for ~90% of cases of HTN in adolescents, rarely in young children
- secondary HTN
  - identifiable cause of HTN
  - responsible for majority of childhood hypertension
  - most likely etiology dependent on age (see Table 41), renal parenchymal disease most common cause (60 to 70% of cases)
  - always consider white coat HTN for all ages

Table 41. Etiology of Secondary Hypertension by Age Group

Note: endocrinopathies may include hyperthyroid, hyperparathyroid, Cushing’s syndrome, primary hyperaldosteronism/Conn’s syndrome, pheochromocytoma

Risk Factors
- primary HTN: male gender, positive family history, metabolic syndrome, OSA, African-American, prematurity/low-birth weight
- secondary HTN: history of renal disease, abdominal trauma, family history of autoimmune diseases, umbilical artery catheterization

History
- often asymptomatic, but can include FTT, fatigue, epistaxis
- symptoms of hypertensive emergency
  - neurologic: headache, seizures, focal complaints, change in mental status, visual disturbances
  - cardiovascular: symptoms of MI or heart failure (chest pain, palpitations, cough, shortness of breath)
- symptoms of secondary HTN: guided by etiology above; ask about medications and recreational drugs (current and past)
Physical
- BP measurement (make sure correct cuff size is used), plot on growth chart, BMI
- look for signs of hypertensive emergency (e.g. full neurologic exam, ophthalmoscopy, precordial exam, peripheral pulses, perfusion status)
- look for signs of secondary HTN

Investigations
- laboratory:
  - urine dipstick for hematuria and/or proteinuria (renal disease), urine catecholamines (pheochromocytoma, neuroblastoma)
  - blood work: renal function tests (electrolytes, Cr, BUN), consider renin and aldosterone levels (RAS, Conn’s syndrome, Wilms’ tumour)
  - other specific hormones if indicated on history and physical
- imaging: echocardiography (coarctation, heart function), abdominal U/S (RAS, abdominal mass), renal radionucleide imaging (renal scarring)
- other: ocular exam

Management
- treat underlying cause
- non-pharmacologic: modify concurrent cardiovascular risk factors (rate reduction, exercise, salt restriction, smoking cessation, etc.)
- pharmacologic: gradual lowering of BP using thiazide diuretics; no antihypertensives have been formally studied in children; if hypertensive emergencies: hydralazine, labetalol, sodium nitroprusside
- management of end organ damage (e.g. retinopathy, LVH)
- consider referral to specialist

Prognosis
- end-organ damage (similar to adults) including: left ventricular hypertrophy, CHF, cerebrovascular insults, renal disease, retinopathy

Neurology

Seizure Disorders
- see Neurology, N14

Differential Diagnosis of Seizures in Children
- benign febrile seizure
- CNS
  - infection, tumour, hypoxic ischemic encephalopathy
  - trauma, hemorrhage
- metabolic causes (e.g. hypoglycemia, hypocalcemia, hyponatremia)
- idiopathic epilepsy and epileptic syndromes
- others:
  - neurocutaneous syndromes
  - arteriovenous malformation
  - drug ingestions/withdrawal
  - seizure mimics

Investigations
- lab tests: CBC, electrolytes, calcium, magnesium, glucose
- toxicology screen if indicated
- EEG, CT/MRI if indicated, e.g. focal neurological deficit or has not returned to baseline after several hours after seizure
- LP, if first-time non-febrile seizure but not indicated for determining recurrence risk of benign febrile seizures or to determine seizure type or epileptic syndrome

CHILDHOOD EPILEPTIC SYNDROMES

Infantile Spasms
- brief, repeated symmetric contractions of neck, trunk, extremities (flexion and extension) lasting 10-30 s
- occur in clusters; often associated with developmental delay; onset 4-8 mo
- 20% unknown etiology (usually good response to treatment); 80% due to metabolic or developmental abnormalities, encephalopathies, or are associated with neurocutaneous syndromes (usually poor response to treatment)
can develop into West syndrome (infantile spasms, psychomotor developmental arrest, and hyperactivity) or Lennox Gastaut (see below)

- typical EEG: hypsarrhythmia (high voltage slow waves, spikes and polyspikes, background disorganization)
- management: ACTH, vigabatrin, benzodiazepines

Lennox-Gastaut

- characterized by triad of 1) multiple seizure types, 2) diffuse cognitive dysfunction and 3) slow generalized spike and slow wave EEG
- onset commonly 3-5 yr of age
- seen with underlying encephalopathy and brain malformations
- management: valproic acid, benzodiazepines and ketogenic diet; however, response often poor

Juvenile Myoclonic Epilepsy (Janz Syndrome)

- myoclonus particularly in morning; frequently presents as generalized tonic-clonic seizures
- adolescent onset (12-16 yr of age); autosomal dominant with variable penetrance
- typical EEG: 3.5-6 Hz irregular spike and wave, increased with photic stimulation
- management: lifelong treatment (valproic acid); excellent prognosis

Childhood Absence Epilepsy

- multiple daily absence seizures lasting <30 s without post-ictal state that may resolve spontaneously or become generalized in adolescence
- peak age of onset 6-7, F>M, strong genetic predisposition
- typical EEG: 3/s spike and wave
- management: valproic acid or ethosuximide

Benign Focal Epilepsy of Childhood with Rolandic/Centrotemporal Spikes

- focal motor seizures involving tongue, mouth, face, upper extremity usually occurring in sleep-wake transition states; remains conscious, but aphasic post-ictally
- onset peaks at 5-10 yr of age, 16% of all non-febrile seizures; remits spontaneously in adolescence without sequelae
- typical EEG: repetitive spikes in centrotemporal area with normal background
- management: frequent seizures controlled by carbamazepine, no medication if infrequent seizures

General Approach to Treatment

- medication
  - initiate: treatment with drug appropriate to seizure type; often initiate anticonvulsants if >2 unprovoked afebrile seizures within 6-12 mo
  - optimize: start with one drug and increase dosage until seizures controlled
  - if no effect, switch over to another before adding a second antiepileptic
  - continue anticonvulsant treatment until patient free of seizures for >2 yr, then wean medications over 4-6 mo
- ketogenic diet (high fat diet): used in patients who do not respond to polytherapy or who do not wish to take medication (valproic acid contraindicated in conjunction with ketogenic diet because may increase hepatotoxicity)
- education for patient and parents including education and precautions in daily life (e.g. buddy system, showers instead of baths)
- legal obligation to report to Ministry of Transportation if patient wishes to drive

Generalized and Partial Seizures

- see Neurology, N14

Febrile Seizures

Epidemiology

- most common cause of seizure in children (3-5% of children)
- M>F; age 6 mo-6 yr

Clinical Presentation

- short (~1 min, always <5 min) generalized tonic-clonic seizure with short post-ictal state
- often with associated illness or fever and family history
- no evidence of CNS infection/inflammation before or after seizure; no history of non-febrile seizures

Ketogenic Diet and other Dietary Treatments for Epilepsy

Cochrane DB of Syst Rev 2012;3:CD001903

Study: Systematic review of all studies of ketogenic and related diets. Included the review of 4 RCTs, 6 prospective studies and 5 retrospective studies.

Population: Adults and children with diagnosed epilepsy of any type.

Intervention: Ketogenic diet, control (placebo diet, any treatment with known antiepileptic properties)

Main outcome measure: Seizure control at 3, 6, 12 mo.

Results: Studies showed a response rate of at least 38-50% seizure reduction at 3 mo. This response was maintained for up to a year. A range of side effects were reported. The most frequent were gastrointestinal effects (30%).

Conclusion: The ketogenic diet is a valid option for people with medically-intractable epilepsy.

</tbody>
</table>

Workup
- history: determine focus of fever, description of seizure, medications, trauma history, development, family history
- exam: LOC, signs of meningitis, neurological exam, head circumference, focus of infection
- septic work-up including LP if suspecting meningitis (strongly consider if child <12 mo; consider if child is 12-18 mo; only if meningeal sign present if child >18 mo)
- if simple febrile seizure, investigations only for determining focus of fever
- EEG not warranted unless complex febrile seizure or abnormal neurologic findings

Management
- counsel and reassure patient and parents:
  - febrile seizures do not cause brain damage
  - very small risk of developing epilepsy: 9% in child with multiple risk factors (i.e. development or neurological abnormalities prior to seizure, family history of complex febrile seizure, multiple simple febrile seizure); 2% in child with febrile simple seizures compared to 1% in general population
  - 33% chance of recurrence (mostly within 1 yr of first seizure and in children <1 yr old)
  - antipyretics (e.g. acetaminophen) and fluids for comfort (though neither prevent seizure)
  - prophylaxis not recommended
  - if high risk for recurrent or prolonged seizures, have rectal or sublingual lorazepam at home
  - treat underlying cause of fever

Recurrent Headache
- see Neurology, N38

Differential Diagnosis
- primary headache: tension, migraine, cluster
- secondary headache: see Neurology, N39

General Assessment
- if unremarkable history and neurological and general physical exam is negative, most likely diagnosis is migraine or tension-type headache
- CT or MRI if history or physical reveals red flags
- inquire about level of disability, academic performance, after-school activities

MIGRAINE
- 4-5% of school aged children; F>M after puberty
- heterogeneous autosomal dominant inheritance with incomplete penetrance (majority of patients have a positive family history)

Types
- common (no aura): most common in children, often with intense nausea and vomiting
- classic (with aura)
- complicated: basilar, ophthalmoplegic, confusional, hemiplegic

Clinical Features
- infancy: spells of irritability, sleepiness, pallor, and vomiting
- young child: periodic headaches with nausea and vomiting that is relieved by rest
- older child: usually unilateral throbbing headaches with photophobia or phonophobia

Prognosis and Treatment
- >50% undergo spontaneous prolonged remission after 10 yr of age
- non-pharmacological treatment and prophylaxis: rest in quiet, dark room, avoid triggers (poor sleep, stress, chocolate, caffeine), biofeedback techniques, exercise, magnesium supplementation
- pharmacological treatment: early analgesia (e.g. ibuprofen), sumatriptan or other tryptans if >12 yr of age
- pharmacological prophylaxis: β-blockers (e.g. propranolol), antihistamines, antidepressants (e.g. amitriptyline/nortriptyline), calcium-channel blockers, anticonvulsants (e.g. divalproex sodium)
TENSION HEADACHES

Clinical Features
- usually bilateral pressing tightness (aching, non-throbbing) anywhere on the cranium
- building in intensity; lasting 30 min-days
- no nausea/vomiting, not aggravated by physical activity

Management
- reassurance, supportive counseling (e.g. explain how stress may cause a headache)
- rule out refractory errors in eyesight
- mild analgesia (NSAIDs, acetaminophen)

ORGANIC HEADACHES
- organic etiology often suggested with occipital headache especially in pre-school aged child and red flags (e.g. ataxia)
- with increased ICP
  - etiology: brain tumours, hydrocephalus, meningitis, encephalitis, cerebral abscess, pseudotumour cerebri, subdural hematoma
  - characteristics: diffuse early morning headaches, early morning vomiting, headache worsened by increased ICP (cough, sneeze, Valsalva); as ICP increases, headache is constant and child is lethargic and irritable
- without increased ICP
  - etiology: cerebral arteriovenous malformation (AVM), aneurysm, collagen vascular diseases, subarachnoid hemorrhage, stroke

Hypotonia
- decreased resistance to passive movements – “floppy baby”

Differential Diagnosis
- central
  - chromosomal (Down, Prader-Willi, Fragile X syndromes)
  - metabolic (hypoglycemia, kernicterus)
  - perinatal problems (asphyxia, ICH)
  - endocrine (hypothyroidism, hypopituitarism)
  - infections (TORCH)
  - CNS malformations
  - dysmorphic syndromes
- peripheral
  - motor neuron (e.g. spinal muscular atrophy, polio)
  - peripheral nerve (e.g. Charcot-Marie-Tooth syndrome)
  - neuromuscular junction (e.g. myasthenia gravis)
  - muscle fibres (e.g. mitochondrial myopathy, muscular dystrophy, myotonic dystrophy)

History and Physical
- proper assessment of tone requires accurate determination of gestational age
- differentiate between upper motor neuron from lower motor neuron signs; spontaneous posture (spontaneous movement, movement against gravity, frog-leg position); muscle weakness; joint mobility (hyperextensibility); muscle bulk, presence of fasciculations
- postural maneuvers:
  - traction response: pull to sit, look for flexion of arms to counteract traction and head lag
  - axillary suspension: suspend infant by holding at axilla and lifting; hypotonic babies will slip through grasp because of low shoulder girdle tone
  - ventral suspension: infant is prone and supported under the abdomen by one hand; infant should be able to hold up extremities; inverted “U” posturing demonstrates hypotonia, i.e. baby will drape self over examiner’s arms
- dysmorphic features, cognitive ability, reflexes, power

Investigations
- rule out systemic disorders (e.g. blood glucose, CK and serum/urine investigations for multiple etiologies including mitochondrial causes)
- neuroimaging: MRI/MRS when indicated
- EMG, muscle biopsy/NCS
- chromosome analysis, genetic testing, metabolic testing, neuromuscular testing

Treatment
- depends on etiology: some treatments available for specific diagnosis
- counsel parents on prognosis and genetic implications
- refer patients for specialized care, refer for rehabilitation, OT, PT, assess feeding ability
Cerebral Palsy (CP)

Definition
• a symptom complex, not a disease
• non-progressive central motor impairment syndrome due to insult to or anomaly of the immature CNS
• incidence: 1.5-2.5 per 1000 live births (industrialized nations)
• life expectancy is dependent on the degree of mobility and intellectual impairment, not on severity of CNS lesion

Etiology
• often obscure, no definite etiology identified in 1/3 of cases
• 10% related to intrapartum asphyxia; 10% due to postnatal insult (infections, asphyxia, prematurity with intraventricular hemorrhage and trauma)
• association with low birth weight babies

Clinical Presentation

</tbody>
</table>

Other Signs
• uncoordinated swallowing \rightarrow aspiration
• microcephaly (25%)
• seizures
• mental retardation, learning disabilities
• delay in motor milestones
• visual, hearing impairment

Investigations
• may include metabolics, chromosome studies, serology, neuroimaging, EMG, EEG (if seizures), ophthalmology, audiology

Treatment
• maximize potential through multidisciplinary services such as primary care physician, OT, PT, SLP, school supports, etc.
• orthopedic management (e.g. dislocations, contractures, rhizotomy)
• management of symptoms: spasticity (baclofen, Botox®), constipation (stool softeners)

Neurocutaneous Syndromes

characterized by tendency to form tumours of the CNS, PNS, viscera and skin

Neurofibromatosis Type I (NF-1)
• autosomal dominant but 50% are the result of new mutations
• also known as von Recklinghausen disease
• incidence 1:3000, mutation in NF1 gene on 17q11.2 (codes for neurofibromin protein)
• learning disorders, abnormal speech development and seizures are common
• diagnosis of NF-1 requires 2 or more of:
  • ≥6 café-au-lait spots (>5 mm if prepubertal, >1.5 cm if postpubertal)
  • ≥2 neurofibromas of any type or one plexiform neurofibroma
  • ≥2 Lisch nodules (hamartomas of the iris)
  • optic glioma
  • freckling in the axillary or inguinal region
  • a distinctive bony lesion (e.g. sphenoid dysplasia, cortical thinning of long bones)
  • a first degree relative with confirmed NF-1

In neurocutaneous syndromes, the younger the child at presentation, the more likely they are to develop mental retardation.
**Neurofibromatosis Type II (NF-2)**
- autosomal dominant
- incidence 1:33,000
- characterized by predisposition to form intracranial, spinal tumours
- diagnosed when either bilateral vestibular schwannomas found, or a first-degree relative with NF-2 and either a neurofibroma, meningioma, glioma, or schwannoma
- also associated with posterior subcapsular cataracts
- treatment consists of monitoring for tumour development and surgery

**Sturge-Weber Syndrome**
- port-wine nevus syndrome in V1 distribution with associated angiomatous malformations of the brain causing contralateral hemiparesis and hemiatrophy
- also associated with seizure, glaucoma and mental retardation

**Tuberous Sclerosis**
- autosomal dominant inheritance; 50% new mutations
- adenoma sebaceum (angiokeratomas on face, often in malar distribution), Shagreen patch (isolated raised plaque over lower back, buttocks), “ash leaf” hypopigmentation seen with Wood’s lamp (UV light)
- cardiac rhabdomyomas, kidney angiomyolipoma, mental retardation and seizures
- cerebral cortex tubers (areas of cerebral dysplasia); subependymal nodules (SEN) may evolve into giant cell astrocytomas (may cause obstructive hydrocephalus)
- calcifications within the SEN are seen on CT, MRI (especially around the foramen of Monro)
  - these may obstruct the foramen and cause hydrocephalus

---

**Acute Disseminated Encephalomyelitis (ADEM)**

**Epidemiology**
- median age of onset 5-8 yr; male predominance
- annual incidence in North America is estimated to be 0.4 per 100,000 children <20 yr of age

**Pathophysiology**
- immune-mediated inflammatory disorder of the CNS; characterized by a widespread demyelination predominantly affecting the white matter of the brain and spinal cord (similar to multiple sclerosis)
- usually preceded by a viral infection or vaccination
- absence of clear precedent event has been reported in 26% of patients

**Clinical Presentation**
- often occurs 2 d to 4 wk after a clinically evident infection or vaccination
- clinical course is rapidly progressive, develops over hours to maximum deficits within days
- headache, nausea, vomiting, pyrexia, malaise
- rapid onset encephalopathy, multifocal deficits, seizures
- pyramidal syndrome, cerebellar ataxia, brainstem involvement

**Investigations**
- LP: CSF showing variable pleocytosis and oligoclonal banding
- MRI: large, multifocal, poorly marginated regions of demyelination affecting bilateral subcortical white matter, and deep grey matter (thalamus, basal ganglia); lesions show complete or partial resolution on follow-up, with absence of new clinically silent lesions

**Treatment**
- high dose corticosteroids and supportive measures

**Prognosis**
- favourable, though some residual deficits often exist
**Respirology**

**Approach to Dyspnea**

- see Table 1, *Average Vitals at Various Ages*, P3

![Diagram](https://via.placeholder.com/150)

**Upper Respiratory Tract Diseases**

- see *Otolaryngology*, OT44
- diseases above the thoracic inlet characterized by inspiratory stridor, hoarseness, and suprasternal retractions
- differential diagnosis of stridor: croup, bacterial tracheitis, epiglottitis, foreign body aspiration, subglottic stenosis (congenital or iatrogenic), laryngomalacia/tracheomalacia (collapse of airway cartilage on inspiration)

**Table 44. Common Upper Respiratory Tract Infections in Children**

</tbody>
</table>
Lower Respiratory Tract Diseases

- obstruction of airways below thoracic inlet, produces more expiratory sounds
- classic symptom: wheezing

Differential Diagnosis of Wheezing

- common
  - asthma: recurrent wheezing episodes, identifiable triggers; typically over 6 yr
  - bronchiolitis: first episode of wheezing; usually under 1 yr
  - recurrent aspiration: often neurological impairment
  - pneumonia: fever, cough, malaise
- uncommon
  - foreign body: acute unilateral wheezing and coughing
  - cystic fibrosis: prolonged wheezing, unresponsive to therapy
  - bronchopulmonary dysplasia: often develops after prolonged ventilation in the newborn
- rare
  - congestive heart failure
  - mediastinal mass
  - bronchiolitis obliterans
  - tracheobronchial anomalies

Pneumonia

Etiology
- inflammation of pulmonary tissue, associated with consolidation of alveolar spaces

Clinical Presentation
- incidence is greatest in first year of life with viral cause being most common in children <5 yr
- cough, wheeze, stridor
- CXR: diffuse, streaky infiltrates bilaterally
- bacterial causes may present with cough, fever, chills, dyspnea, more dramatic CXR changes (e.g. lobar consolidation, pleural effusion)

Management
- see Table 45
- supportive therapy: hydration, antipyretics, humidified O₂

Bronchiolitis

Definition
- LRTI that has wheezing and signs of respiratory distress

Epidemiology
- the most common LRTI in infants, affects 50% of children in first 2 yr of life; peak incidence at 6 mo, winter or early spring
- increased incidence of asthma in later life

Etiology
- respiratory syncytial virus (RSV) (>50%), parainfluenza, influenza, rhinovirus, adenovirus, M. pneumoniae (rare)
Clinical Presentation
- prodrome of URTI with cough and fever
- feeding difficulties, irritability
- wheezing, respiratory distress, tachypnea, tachycardia, retractions, poor air entry lasting for 5-6 d

Investigations
- CXR (only in severe disease, poor response to therapy, chronic episode)
  - air trapping, peribronchial thickening, atelectasis, increased linear markings
- nasopharyngeal swab
  - direct detection of viral antigen (immunofluorescence)
- WBC can be normal

Treatment
- self-limiting disease with symptoms usually lasting 2-3 wk
- mild distress
  - supportive: oral or IV hydration, antipyretics for fever, O₂
- moderate to severe distress
  - as above ± intubation and ventilation as needed
  - consider rebetol (Ribavirin®) in high risk groups: bronchopulmonary dysplasia, CHD, congenital lung disease, immunodeficient
- monthly RSV- Ig or palivizumab (monoclonal antibody against the F-glycoprotein of RSV) is protective against severe disease in high risk groups; case fatality rate <1%
- antibiotics have no therapeutic value unless there is secondary bacterial pneumonia
- indications for hospitalization:
  - hypoxia: O₂ saturation <92% on initial presentation
  - persistent resting tachypnea >60/min and retractions after several salbutamol masks
  - past history of chronic lung disease, hemodynamically significant cardiac disease, neuromuscular problem, immunocompromised
  - young infants <6 mo old (unless extremely mild)
  - significant feeding problems
  - social problem (e.g. inadequate care at home)

Asthma
Definition
- see Respirology, R6
- characterized by recurrent episodes of airway hyperreactivity, bronchospasm and inflammation; reversible small airway obstruction
- very common, presents most often in early childhood
- associated with other atopic diseases such as allergic rhinitis or atopic dermatitis

Clinical Presentation
- episodic bouts of wheezing, dyspnea, tachypnea, cough (usually at night/early morning, with activity or cold exposure)
- physical exam may reveal hyper-resonant chest, prolonged expiration, wheeze

Triggers
- URTI (viral or Mycoplasma), weather (cold exposure, humidity changes), allergens (pets), irritants (cigarette smoke), exercise, emotional stress, drugs (Aspirin®, β-blockers)

Classification
- mild asthma
  - occasional attacks of wheezing or coughing (<2/wk)
  - symptoms respond quickly to inhaled bronchodilator
  - never needs systemic corticosteroids
- moderate asthma
  - more frequent episodes with symptoms persisting and chronic cough
  - decreased exercise tolerance
  - sometimes needs systemic corticosteroids
- severe asthma
  - daily and nocturnal symptoms
  - frequent ER visits and hospitalizations
  - usually needs systemic corticosteroid

Bronchodilators for Bronchiolitis
- Cochrane DB Syst Rev 2010;12:CD001266
- Study: Meta-analysis of prospective, randomized, double-blinded, placebo-controlled trials.
- Patients: 1912 infants (28 trials) up to 24 mo old with bronchiolitis.
- Intervention: Bronchodilators (including albuterol, salbutamol, terbutaline, ipratropium bromide, and adrenergic agents) given oral, subcutaneous, or nebulized vs. placebo.
- Main outcome: Oxygen saturation.
- Results: No clinically significant difference for infants treated with bronchodilators vs. placebo for bronchiolitis. Given the costs and side effects it is not recommended to use bronchodilators as management for bronchiolitis in infants.
Management

- **acute**
  - \( O_2 \) (keep \( O_2 \) saturation >92%) and fluids if dehydrated
  - \( \beta_2 \)-agonists: salbutamol (Ventolin\(^\text{®}\)) 0.03 cc/kg (max 1 cc) in 3 cc NS q20min by mask until improvement, then masks hourly if necessary
  - ipratropium bromide (Atrovent\(^\text{®}\)) if severe: 1 cc added to each of first 3 salbutamol masks
  - steroids: prednisone (2 mg/kg in ER, then 1 mg/kg daily x 4 d) or dexamethasone (0.3 mg/kg/d); in severe disease, use IV steroids
  - continue to observe- can discharge patient if asymptomatic for 2-4 h after last dose

- **chronic**
  - education, emotional support, avoid allergens or irritants, develop an “action plan”
  - exercise program (e.g. swimming)
  - monitor respiratory function with peak flow meter (improves self-awareness of status)
  - PFTs for children >6 yr
  - reliever therapy: short acting \( \beta_2 \)-agonists (e.g. salbutamol)
  - controller therapy (first line therapy for all children): low dose daily inhaled corticosteroids
  - second line therapy for children <12 yr: moderate dose of daily inhaled corticosteroids
  - second line therapy for children >12 yr: antileukotriene OR long acting \( \beta_2 \)-agonist in conjunction with low dose inhaled corticosteroids
    - leukotriene receptor antagonist monotherapy may be considered an alternative second line therapy
  - severe asthma unresponsive to first and second line treatments injection immunotherapy
  - aerochamber for children using daily inhaled corticosteroids

- indications for hospitalization
  - pre-treatment \( O_2 \) saturation <92%
  - past history of life-threatening asthma (ICU admission)
  - unable to stabilize with masks q4h
  - concern over environmental issues or family’s ability to cope

Cystic Fibrosis (CF)

- see Respirology, R11

Etiology

- 1 per 3000 live births, mostly Caucasians
- autosomal recessive, \( CFTR \) gene found on chromosome 7 (\( \Delta F508 \) mutation in 70%, but >1600 different mutations identified) resulting in a dysfunctional chloride channel on the apical membrane of cells
- leads to relative dehydration of airway secretions, resulting in impaired mucociliary transport and airway obstruction
- in Ontario, CF is routinely screened in the newborn

Clinical Presentation

- neonatal
  - meconium ileus
  - prolonged jaundice
  - antenatal bowel perforation
- infancy
  - pancreatic insufficiency with steatorrhea and failure to thrive (despite voracious appetite)
  - anemia, hypoproteinemia, hyponatremia
- childhood
  - heat intolerance
  - wheezing or chronic cough
  - recurrent chest infections (\( S. \) aureus, \( P. \) aeruginosa, \( H. \) influenzae)
  - hemoptysis
  - nasal polyps
  - \( \beta_2 \) distal intestinal obstruction syndrome, rectal prolapse
  - clubbing of fingers
- older patients
  - chronic obstructive pulmonary disease
  - infertility (males); decreased fertility (female)

Investigations

- sweat chloride test x 2 (>60 mEq/L)
  - false positive tests: malnutrition, atopic dermatitis, hypothyroidism, hypoparathyroidism, glycogen storage disease type, adrenal insufficiency, G6PD, Klinefelter syndrome, technical issues, autonomic dysfunction, familial cholestasis syndrome
  - false negative tests: technical problem with test, malnutrition, skin edema, mineralocorticoids
Management
• nutritional counselling
  • high calorie diet, pancreatic enzyme replacements, fat soluble vitamin supplements
• management of chest disease
  • physiotherapy, postural drainage
  • exercise
  • bronchodilators
  • aerosolized DNAse and inhaled hypertonic saline
  • antibiotics: depends on sputum C&S (e.g. cephalosporin, cloxacillin, ciprofloxacin, inhaled tobramycin)
  • lung transplantation
• genetic counselling

Complications
• respiratory failure, pneumothorax (poor prognostic sign), cor pulmonale (late), pancreatic fibrosis with diabetes mellitus, gallstones, cirrhosis with portal hypertension, infertility (male)
• early death (current median survival in Canada is 46.6 yr)

Rheumatology

</tbody>
</table>

• must rule out infection, malignancy or an acute orthopedic condition

History
• limp/weight-bearing status
• morning stiffness
• systemic symptoms (fever, rash, weight loss, fatigue)
• past medical illness, intercurrent infection, travel, sick contact history
• family history (arthritis, bleeding disorders, sickle cell anemia, IBD, psoriasis)
Physical
• joint exam (swelling, erythema, warmth, tenderness, deformity, ROM)
• adjacent structures (bone, tendon, muscle, skin)
• gait
• leg length
• neurologic exam

Investigations
• basic: CBC and differential, blood smear, ESR, CRP, x-ray
• as indicated: blood (ANA, RF, culture, viral/bacterial serology, CK, PTT, sickle cell screen, immunoglobulins, complement), urinalysis, synovial fluid (cell count, Gram stain, culture), TB skin test, imaging, BM aspiration, slit lamp exam

Growing Pains
Epidemiology
• age 2-12 yr, M=F

Clinical Presentation
• diagnosis of exclusion
• intermittent, non-articular pain in childhood with normal physical exam findings
• pain at night, often limited to the calf, shin or thigh; typically short-lived and bilateral
• relieved by heat, massage, mild analgesics
• child is well, asymptomatic during the day, no functional limitation
• possible family history of growing pains

Management
• lab investigations not necessary if typical presentation; reassurance and supportive management

Transient Synovitis of the Hip
• benign, self limited disorder, usually occurs after upper respiratory tract infection, pharyngitis, otitis media

Epidemiology
• age 3-10 yr, M>F

Clinical Presentation
• afebrile or low-grade fever, pain typically occurs in hips, knees (referred from hip); painful limp but capable of moving hip through ROM (pain not as pronounced as in joint or bone infections)
• symptoms resolve over 7-10 d

Investigations
• WBC within normal limits; ESR and CRP may be mildly elevated
• joint effusions may be seen on imaging
• diagnosis of exclusion (r/o septic arthritis and osteomyelitis)

Treatment
• symptomatic and anti-inflammatory medications

Adapted from Tse SML, Laxer RM. Pediatrics in Review 2006;27:170-179
Juvenile Idiopathic Arthritis (JIA)

- a heterogeneous group of conditions characterized by persistent arthritis in children <16 yr
- arthritis defined:
  1. joint swelling/effusion OR
  2. >2 of the following:
     - decreased range of motion
     - tenderness or pain on motion
     - increased warmth
- diagnosis
  - arthritis in ≥1 joint(s)
  - duration ≥6 wk
  - onset age <16 yr old
  - with exclusion of other causes of arthritis
  - classification defined by features/number of joints affected in the first 6 mo of onset

Systemic Arthritis (Still’s disease)

- onset at any age, M=F
- once or twice daily fever spikes (>38.5ºC) ≥2 wk; children usually acutely unwell during fever episodes
- extra-articular features: erythematous “salmon-coloured” maculopapular rash, lymphadenopathy, hepatosplenomegaly, leukocytosis, thrombocytosis, anemia, serositis
- arthritis may occur weeks to months later
- high ESR, CRP, WBC, platelet count

Oligoarticular Arthritis (arthritis of 1-4 joints)

- onset early childhood, F>M
- persistent: affects no more than 4 joints during the disease course
- extended: affects more than 4 joints after the first six months
- typically affects large joints: knees > ankles, elbows, wrists; hip involvement unusual
- ANA positive ~60-80%, rheumatoid factor (RF) negative
- screening eye exams for asymptomatic anterior uveitis (occurs in ~30%)
- complications: knee flexion contracture, quadriceps atrophy, leg-length discrepancy, growth disturbances

Polyarticular Arthritis (arthritis of 5 or more joints)

- RF negative
  - onset: 2-4 yr and 6-12 yr, F>M
  - symmetrical involvement of large and small joints of hands and feet, TMJ, cervical spine
- RF positive
  - onset: late childhood/early adolescence, F>M
  - similar to the aggressive form of adult rheumatoid arthritis
  - severe, rapidly destructive, symmetrical arthritis of large and small joints
  - may have rheumatoid nodules at pressure points (elbows, knees)
  - unremitting disease, persists into adulthood

Enthesitis-Related Arthritis

- onset: late childhood/adolescence, M>F
- arthritis and/or enthesitis
- weight bearing joints, especially hip and intertarsal joints
- risk of developing ankylosing spondylitis in adulthood

Psoriatic Arthritis

- onset: 2-4 yr and 9-11 yr, F>M
- arthritis and psoriasis OR arthritis and at least two of:
  - dactylitis, nail abnormalities, or family history of psoriasis in a 1st degree relative
  - asymmetric or symmetric small or large joint involvement

Undifferentiated

- arthritis of unknown cause that persists for 6 wk and either does not fulfill criteria for any category or fulfills criteria for more than one category

Management

- goals of therapy: eliminate inflammation, prevent joint damage, promote normal growth and development as well as normal function, minimize medication toxicity
- exercise to maintain range of motion (ROM) and muscle strength
- multidisciplinary approach: OT/PT, social work, orthopedics, ophthalmology, rheumatology
- 1st line drug therapy: NSAIDs, intra-articular corticosteroids
2nd line drug therapy:
- DMARDs: methotrexate, sulfasalazine, leflunamide
- corticosteroids: acute management of severe arthritis, systemic symptoms of JIA, topical eye drops for uveitis
- biologic agents

Reactive Arthritis

- see Rheumatology, RH23
- arthritis (typically the knee) follows bacterial infection especially with *Salmonella*, *Shigella*, *Yersinia*, *Campylobacter*, *Chlamydia*, and most commonly *Streptococcus* (post-streptococcal reactive arthritis)
- typically resolves spontaneously
- may progress to chronic illness or Reiter's syndrome (urethritis, conjunctivitis)

Lyme Arthritis

- see Infectious Diseases, ID26
- caused by spirochete *Borrelia burgdorferi*
- incidence highest among 5-10 yr olds
- do not treat children <8 yr old with doxycycline (may cause permanent tooth discoloration)

Systemic Lupus Erythematosus (SLE)

- see Rheumatology, RH11
- autoimmune illness affecting multiple organ systems
- incidence 1 per 1000, more commonly age >10, F:M = 10:1
- childhood-onset SLE vs. adult-onset SLE:
  - children have more active disease
  - children are more likely to have renal disease
  - children receive more intensive drug therapy and sustain more damage

Vasculitides

HENOCHE-SCHÖNLEIN PURPURA (HSP)
- most common vasculitis of childhood, peak incidence 4-10 yr, M:F = 2:1
- vasculitis of small vessels
- often have history of URTI 1-3 wk before onset of symptoms

Clinical Presentation
- clinical triad: 1) palpable purpura, 2) abdominal pain, 3) arthritis
- skin: palpable, non-thrombocytopenic purpura in lower extremities and buttocks, edema, scrotal swelling
- joints: arthritis/arthritis involving large joints associated with painful edema
- GI: abdominal pain, GI bleeding, intussusception
- renal: microscopic hematuria, IgA nephropathy, proteinuria, hypertension, renal failure in <5%

Management
- mainly supportive
- anti-inflammatories for joint pain, corticosteroids for select patients
- monitor for protein on urinalysis every month for 6 mo, checking for renal disease, which may develop late (immunosuppressive therapy if severe)

Prognosis
- self-limited, resolves within 4 wk
- recurrence in about one third of patients
- long term prognosis dependent on severity of nephritis
KAWASAKI DISEASE
• acute vasculitis of unknown etiology (likely triggered by infection)
• medium-sized vasculitis with predilection for coronary arteries
• most common cause of acquired heart disease in children in developed countries
• peak age: 3 mo – 5 yr; Asians > Blacks > Caucasians

Diagnostic Criteria
• fever persisting 5 d or more AND
• 4 of the following features:
  1. bilateral conjunctival injection
  2. red infected fissured lips, strawberry tongue, injected pharynx
  3. changes of the peripheral extremities
     • acute phase: peripheral edema, peripheral erythema
     • subacute phase: peeling from tips of fingers and toes
  4. polymorphous rash
  5. cervical lymphadenopathy >1.5 cm in diameter
• exclusion of other diseases (e.g. scarlet fever, measles)
• atypical Kawasaki disease: less than 5 of 6 diagnostic features but coronary artery involvement

Management
• high (anti-inflammatory) dose of ASA while febrile
• low (anti-platelet) dose of ASA in subacute phase until platelets normalize or longer if coronary artery involvement
• IV immunoglobulin (2 g/kg) within 10 d of onset reduces risk of coronary aneurysm formation
• baseline 2D-ECHO and follow up periodic 2D-ECHO (usually at 6 wk)

Complications
• coronary artery vasculitis with aneurysm formation occurs in 20-25% of untreated children, <5% if receive IVIG within 10 d of fever
• 50% of aneurysms regress within 2 yr
• anticoagulation for multiple or large coronary aneurysms
• risk factors for coronary disease: male, age <1 or >9 yr, fever >10 d, Asian or Hispanic ethnicity, thrombocytopenia, hyponatremia

Basic Surgical Techniques

Sutures and Suturing

ANESTHESIA
- debride and irrigate before injecting anesthetic
- toxicity of mixtures (i.e. lidocaine + bupivicaine) is no greater than its individual components

Table 5. Toxic Limit and Duration of action (1 cc of 1% solution contains 10 mg lidocaine)

<table>
<thead>
<tr>

<td>7 mg/kg, lasts 2-6 h</td>
</tr>
<tr>
<td>Bupivicaine (Marcaine®)</td>
<td>2 mg/kg, lasts 2-4 h</td>
<td>3 mg/kg, lasts 3-7 h</td>
</tr>
</tbody>
</table>

IRRIGATION AND DEBRIDEMENT
- irrigate copiously with a physiologic solution such as Ringer’s lactate or normal saline to remove surface clots, foreign material, and bacteria
- debride all obviously devitalized tissue, irregular or ragged wounds must be excised to produce sharp wound edges that will assist healing when approximated

SUTURES
- use of a particular suture material is highly dependent on surgeon preference. However, skin should be closed with a non absorbable when trauma
- suture material divided by two categories (see Table 6)

Table 6. Suture Materials: Absorbable vs. Non-absorbable and Monofilament vs. Multifilament

</tbody>
</table>

Steps to Ensuring Good Suturing

Cosmesis:
- Incisions should be made along relaxed skin tension lines
- Attain close apposition of wound edges
- Minimize tension on skin by closing in layers
- Evert wound edges
- Use appropriately sized suture for skin closure (5-0, 6-0 on face; 3-0, 4-0 elsewhere)
- Ensure equal width and depth of tissue on both sides
- Remove sutures within 5-7 d from the face, 10-14 d from scalp/torsq/ extremities

Basic Suturing Techniques

Basic Suture Methods (Figure 12)
- simple interrupted: can be used in almost all situations
- sub-cuticular: good cosmetic result but weak, used in combination with deep sutures; not used in trauma
- vertical mattress: for areas difficult to evert (e.g. dorsum of the hand)
- horizontal mattress: evertting, time saving
- continuous over and over (aka “running”, “baseball stitch”): time saving, good for hemostasis

Basic Principles
- minimize tissue trauma: follow curve of needle, handle wound edges gently (use toothed forceps), use just enough tension to approximate edges (do not strangulate)
- use the finest needle and suture possible
- ensure good cosmesis (see sidebar)
Other Skin Closure Materials

- tapes: may be indicated for superficial wounds and those with opposable edges. Tape cannot be used on actively bleeding wounds. When placed across the incision, will prevent surface marks and can be used primarily or after surface sutures have been removed. Tape burns may occur if there is excessive tension or swelling around the incision
- skin adhesives: e.g. 2-octylcyanoacrylate (e.g. Dermabond®) works well on small areas without much tension or shearing. May cause irreversible tattooing
- staples: steel-titanium alloys that incite minimal tissue reaction (healing is comparable to wounds closed by suture)

Excision

- incise along relaxed skin tension lines to minimize appearance of scar (Figure 13)
- use elliptical incision to prevent “dog ears” (heaped up skin at end of incision)
- if needed, undermine skin edges to decrease wound tension
- use layered closure including dermal sutures when wound is deeper than superficial (decreases tension)

Skin Biopsy Types and Techniques

SHAVE BIOPSY
- used for superficial lesions where sampling of the full thickness of the dermis is not necessary
- most suitable lesions for shave biopsies are either elevated above the skin or have pathology confined to the epidermis (e.g. seborrheic or actinic keratoses, skin tags, warts, and superficial basal cell or squamous cell carcinomas)
- rapid, requires little training, and does not require sutures for closure
- should not be used for pigmented lesions – an unsuspected melanoma cannot be properly staged if partially removed

PUNCH BIOPSY
- involves the removal of a core-shaped piece of tissue, performed with round, disposable knives ranging in diameter from 2 to 10 mm
- allows sampling of the deep dermis
- can be used for the diagnosis and treatment of small pigmented lesions and atypical moles
- punch biopsy wounds can be closed with suture or left to heal by secondary intention. Punches greater than 3 mm may produce scarring and are best closed with one or two sutures
- has low incidence of infection, bleeding, nonhealing, significant scarring

EXCISIONAL BIOPSY
- performed for lesions that require complete removal for diagnostic or therapeutic purposes
- performed for lesions that cannot be adequately punch biopsied due to size, depth, or location
- requires the greatest amount of expertise and time
- always requires sutures for closure

TECHNIQUE

General
- all biopsies performed in clinic are done using aseptic technique, but are not sterile
- sterile gloves are indicated for biopsies and excisions in all patients

Preparing the Site
- common skin antiseptics (betadine, chlorhexidine) can be used to prepare the biopsy site
- chlorhexidine is used in concentrations ranging from 0.5-4%. This higher concentration cannot be used on the face as it could get into the eyes and may burn or cause damage
- mark the intended lesion and surgical margins with a surgical marker since they may be temporarily obliterated following injection of the anesthetic
- for all biopsies, a sterile drape technique is indicated. A fenestrated surgical drape is placed around the biopsy site after the area is cleansed and anesthetized

Anesthesia
- most commonly used local anesthetic is 1% or 2% lidocaine
- small amounts of epinephrine are added to constrict blood vessels, decrease bleeding, prolong anesthesia, and limit lidocaine toxicity. The local with epinephrine can be injected directly into the lesion
- local anesthetics with epinephrine may be used anywhere in the body including the digits
- epinephrine should be avoided in patients with history of vascular compromise
- a field block should be performed for larger lesions by placing a ring of anesthetic around the surgical site, advancing and injecting through a site that has been previously anesthetized
Wounds

Causal Conditions

- laceration: cut or torn tissue
- abrasion: superficial skin layer is removed, variable depth
- contusion: injury caused by forceful blow to the skin and soft tissue; entire outer layer of skin intact yet injured
- avulsion: tissue/limb forcefully separated from surrounding tissue, either partially or fully; “de-gloving”
- puncture wounds: opening relatively small as compared with depth (e.g. needle)
  - includes bite wounds
- crush injuries: caused by compression
- thermal and chemical wounds

Principles of Wound Healing

- wound: disruption of the normal anatomical relationships of tissue as a result of injury

STAGES OF WOUND HEALING

- see Figure 14
- growth factors released by tissues play an important role
- scar is mature once it has completed the final stage

FACTORS INFLUENCING WOUND HEALING

Local (reversible/controllable):
- mechanical (local trauma, tension)
- blood supply (ischemia/circulation)
- temperature
- technique and suture materials
- retained foreign body
- infection
- hematoma/seroma (↑ infection rate)
- venous hypertension
- peripheral vascular disease

General (often irreversible):
- age
- nutrition (protein, vitamin C, O₂)
- smoking
- chronic illness (e.g. diabetes, cancer, CVD)
- immunosuppression (steroids, chemo, radiation)
- collagen vascular disease
- tissue irradiation
- retained foreign body
- tissue irradiation
- infection
- hematoma/seroma (↑ infection rate)
- chronic illness (e.g. diabetes, cancer, CVD)
- immunosuppression (steroids, chemo, radiation)
- collagen vascular disease
- tissue irradiation
- retained foreign body
- tissue irradiation
- infection

PHASE | PROCESS
--- | ---
1. Inflammatory Phase (Reactive) (Days 1-6) | 1. Hemostasis – vasoconstriction + platelet plug
- Limits damage, prevents further injury
- Debris and organisms cleared via inflammatory response:
  - Neutrophils (24-48 h)
  - Macrophages: critical to wound healing by orchestrating growth factors for collagen production (48-96 h)
  - Lymphocytes: role poorly defined (5-7 d)
2. Proliferative Phase (Regenerative) (Day 4 – Week 3) | 1. Collagen synthesis (mainly type III)
2. Angiogenesis
3. Epithelialization
- Fibroblasts attracted and activated by macrophage growth factors
- Reparative process: re-epithelialisation, matrix synthesis, angiogenesis (relieves ischemia)
- Tensile strength begins to increase at days 4-5
3. Remodeling Phase (Maturation) (Week 3 – 1 year) | 1. Contraction
2. Scarring
3. Remodeling of scar
- Increasing collagen organization and stronger crosslinks
- Type I collagen replaces Type III until normal 4:1 ratio achieved
- Peak tensile strength at 60 d – 80% of preinjury strength

Figure 14. Stages of wound healing

Myofibroblasts are the cells responsible for wound contraction. They do this at a rate of less than 0.75 mm/d.
ABNORMAL HEALING

Hypertrophic Scar
• scar remains roughly within boundaries of original injury
• red, raised, widened, frequently pruritic
• common sites: back, shoulder, sternum
• treatment: pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision if other options fail (however, may still recur), typically improves with time

Keloid Scar
• scar extends beyond boundaries of original injury
• frequently pruritic, often painful; collagen in whorls rather than bundles
• common sites: sternum, deltoid, earlobe; more common in darker skinned people
• treatment: pressure garments, silicone gel sheeting, corticosteroid injection, radiation therapy ± surgical excision as a last resort

Chronic Wound
• fails to heal primarily within 4-6 wk
• common chronic wounds include diabetic, pressure and venous stasis ulcers
• treatment: may heal with meticulous wound care; may also require surgical intervention
• Marjolin's ulcer: squamous cell carcinoma arising in a chronic wound secondary to genetic changes caused by chronic inflammation → consider biopsy of chronic wound

WOUND CLOSURE

Primary (1°) Closure (First Intention)
• definition: wound closure by direct approximation of edges within hours of wound creation (i.e. with sutures, staples, skin graft, etc.)
• indication: recent (<6 h, longer with facial wounds), clean wounds
• contraindications: animal/human bites (except on face), crush injuries, infection, long time lapse since injury (>6-8 h), retained foreign body

Secondary (2°) Closure/Spontaneous Healing (Second Intention)
• definition: wound left open to heal spontaneously (epithelialization 1 mm/d from wound margins in concentric pattern), contraction (myofibroblasts) and granulation – maintained in inflammatory phase until wound closed; requires dressing changes; inferior cosmetic result
• indication: when 1° closure not possible or indicated (see Primary Closure, above)

Tertiary (3°) Closure/Delayed Primary Closure (Third Intention)
• definition: intentionally interrupt healing process (e.g. with packing), then wound can be closed at 4-10 d post-injury after granulation tissue has formed and there is <10^6 bacteria/gram of tissue
• indication: contaminated (high bacterial count), long time lapse since initial injury, severe crush component with significant tissue devitalization
• prolongation of inflammatory phase decreases bacterial count and lessens chance of infection after closure

Contaminated and Infected Wounds

Definitions
• contamination: the presence of non-replicating microorganisms within a wound
• colonization: the presence of replicating microorganisms within a wound
• infection: greater than 10^5 microorganisms in a wound without intact epithelium, a wound may also be infected with small amounts of a very virulent organism (e.g. GBS)

Management of Acute Contaminated Wound (<24 h)
• cleanse and irrigate open wound with physiologic solution (NS or RL)
• evaluate for injury to underlying structures (vessels, nerve, tendon and bone)
• control active bleeding
• debridement: removal of foreign material, devitalized tissue, old blood
  • surgical debridement: blade and irrigation if indicated
• systemic antibiotics are commonly indicated for obvious infection, wound older than 8 h, severely contaminated, immunocompromised, involvement of deeper structures (e.g. joints, fractures)
• ± tetanus toxoid 0.5 mL IM ± tetanus immunoglobulin 250 U deep IM (see Table 7 and Table 8)
• ± post-exposure treatment of
  • hepatitis B, HIV, hepatitis C (if titres confirmed at 6 mo)

Risk Factors for Infection
• Virulence of the infecting microorganism
• Amount of bacteria present
• Host resistance
• re-evaluate in 24-48 h for signs of deep infection
  ▪ open infected portion of wound by removing sutures if evidence of infection (i.e. erythema, warmth, pain, discharge)

</tr>
</tbody>
</table>

* 0.5 mL of combined tetanus and diphtheria toxoids ± acellular pertussis
** Tetanus immune globulin, 250 U given at a separate site from Td/Tdap
~ Yes, if >10 yr since last booster
§ Yes, if >5 yr since last booster

**Management of Contaminated Wounds (>24 h, including ulcers)**

- irrigation and debridement
  ▪ traumatic tattooing can occur if foreign materials left in wound
- systemic antibiotics indicated if there is concern of infection (e.g. redness, swelling, pain, clinically unwell)
- topical antimicrobials: beneficial for minor wounds, but no additional benefit for wounds requiring systemic antibiotics. May aid in healing of chronic wounds
- closure: final closure via secondary intention (most common), delayed wound closure (3º closure), skin graft or flap; successful closure depends on bacterial count of ≤10⁵/cm³ prior to closure and frequent dressing changes

**BITES**

- see [Emergency Medicine, ER46](#)

**Dog and Cat Bites**

- pathogens: *Pasteurella multocida, S. aureus, S. viridans*
- investigations: same as for human bites; see below
- treatment: Clavulin® (500 mg PO q8h started immediately – amoxicillin + clavulanic acid)
  ▪ consider rabies prophylaxis if animal has symptoms of rabies or unknown animal
  ▪ ± rabies lg (20 IU/kg around wound, or 1M) and 1 of the 3 types of rabies vaccines
    (1.0 mL IM in deltoid, repeat on days 3, 7, 14, 28)
  ▪ aggressive irrigation with debridement
  ▪ healing by secondary intention is mainstay of treatment
  ▪ only consider primary closure for bite wounds on the face; otherwise primary closure is contraindicated
  ▪ contact Public Health if animal status unknown

**Human Bites**

- pathogens: *Staphylococcus > α-hemolytic Streptococcus > Eikenella corrodens > Bacteroides*
- mechanism: most commonly over dorsum of MCP from a punch in mouth; “fight-bite”
- serious, as mouth has 10⁹ microorganisms/mL, which get trapped in joint space when fist unclenches and overlying skin forms an air-tight covering ideal for anaerobic growth – can lead to septic arthritis
- investigations:
  ▪ radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  ▪ culture for aerobic and anaerobic organisms, Gram stain
- treatment:
  ▪ urgent surgical exploration of joint, drainage and debridement of infected tissue
  ▪ wound must be copiously irrigated
  ▪ Clavulin® 500 mg PO q8h, clindamycin 300 mg PO q6h + ciprofloxacin 500 mg PO q12h (if allergic to penicillin) + secondary closure
  ▪ splint
Dressings

- there is no one dressing for any given type of wound. Dressing selection depends on the wound characteristics
  - as the wound progresses through healing it will require different types of dressings, therefore, routine inspection is recommended
  - principles of dressings:
    - moist vs. dry wounds (see Table 9)
    - purpose of dressings should be to keep wound appropriately moist (i.e. moistening dry wounds or removing excess exudate/blood from wet wounds)
    - clean vs. infected wounds
      - clean wounds can be dressed with petroleum based gauze, which is non-adhering to epithelializing tissue; requires secondary dressing
      - infected wounds can be dressed with iodine gauze, silver-containing, or antimicrobial dressings
    - wide-based vs. cavitary/tunneling wounds
      - cavitary or tunnelling wounds (i.e. through a fascial layer) can be packed with saline-soaked (non-infected), betadine-soaked (infected) ribbon gauze, or other easily retrievable one-piece moisture providing dressing

Table adapted from Grabb & Smith’s Plastic Surgery 6th Edition Chapter 3, Table 3.3

Reconstruction

SKIN GRAFTS

Definition
- skin that is harvested from a donor site and transferred to the recipient site and that does not carry its own blood supply. Survival requires the generation of new blood vessels from the recipient site bed. They are classified according to the depth of dermis they contain: full thickness (entire epidermis + dermis) vs. split-thickness (epidermis + partial dermis)

Donor Site Selection
- must consider size, hair pattern, texture, thickness of skin, and colour (facial grafts best if taken from “blush zones” above clavicle e.g. pre/post auricular or neck)
- partial thickness grafts usually taken from inconspicuous areas (e.g. buttocks, lateral thighs, etc.)

Partial Thickness Skin Graft Survival
- 3 phases of skin graft “take”
  1. plasmatic imbibition: diffusion of nutrition from recipient site (first 48 h)
  2. inosculation: vessels in graft connect with those in recipient bed (day 2-3)
  3. neovascular ingrowth: graft revascularized (day 3-5)
- requirements for survival
  - bed: well-vascularized (unsuitable: bone, tendon, heavily irradiated, infected wounds, etc.)
  - contact between graft and recipient bed: fully immobile (decreased shearing and hematoma formation)
  - staples, sutures, splinting, and appropriate dressings (pressure) are used to prevent movement of graft and hematoma or seroma formation
  - site: low bacterial count (<10^5/cm³, to prevent infection)

Classification of Skin Grafts
1. by species
   - autograft: from same individual
   - allograft (homograft): from same species, different individual
   - xenograft (heterograft): from different species (e.g. porcine)
2. by thickness: see Table 10
Table 10. Skin Grafts

<table>
<thead>
<tr>
<th></th>
<th>Split Thickness Skin Graft</th>
<th>Full Thickness Skin Graft</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Definition</strong></td>
<td>Epidermis and part of dermis</td>
<td>Epidermis and all of dermis</td>
</tr>
<tr>
<td><strong>Donor Site</strong></td>
<td>More sites</td>
<td>Limited donor sites (full thickness skin loss, must be closed 1st or with STSG)</td>
</tr>
<tr>
<td><strong>Healing of Donor Site</strong></td>
<td>Re-epithelialization via dermal appendages in graft and wound edges</td>
<td>Primary closure</td>
</tr>
<tr>
<td><strong>Re-harvesting</strong></td>
<td>~10 d (faster on scalp)</td>
<td>N/A</td>
</tr>
<tr>
<td><strong>Graft Take</strong></td>
<td>Easier; shorter nutrient diffusion distance</td>
<td>Lower rate of survival (thicker, slower vascularization)</td>
</tr>
<tr>
<td><strong>Contraction</strong></td>
<td>Less 1st contraction, greater 2nd contraction (less with thicker graft)</td>
<td>Greater 1st contraction, less 2nd contraction</td>
</tr>
<tr>
<td><strong>Aesthetic</strong></td>
<td>Poor</td>
<td>Good</td>
</tr>
<tr>
<td><strong>Comments</strong></td>
<td>Can be meshed for greater area (see below)</td>
<td>May use on face and fingers</td>
</tr>
<tr>
<td><strong>Advantage</strong></td>
<td>Takes well in less favourable conditions, can cover a larger area</td>
<td>Resists contraction, texture/pigment more normal</td>
</tr>
<tr>
<td><strong>Disadvantage</strong></td>
<td>Contracts significantly, abnormal pigmentation, high susceptibility to trauma</td>
<td>Requires well vascularized bed</td>
</tr>
<tr>
<td><strong>Uses</strong></td>
<td>Large areas of skin, granulating tissue beds</td>
<td>Face (colour match), site where thick skin or decreased contracture is desired (e.g. finger)</td>
</tr>
</tbody>
</table>

**mesh graft**
- **advantages**
  - Prevents accumulation of fluids (e.g. hematoma, seroma)
  - Covers a larger area
  - Best for contaminated recipient site
- **disadvantages**
  - Poor cosmetic result (“alligator hide” appearance)
  - Has significant contracture

**common reasons for graft loss:** hematoma/seroma, infection, mechanical force (e.g. shearing, pressure)

**OTHER GRAFTS**

</table>

**FLAPS**
- **Definition:** tissue transferred from one site to another with a known blood supply (random, pedicled or named); not dependent on neovascularization, unlike a graft
- **May Consist of:** skin, subcutaneous tissue, fascia, muscle, bone, other tissue (e.g. omentum)
- **Classification:** based on blood supply to skin (random, axial) and anatomic location (local, regional, distant)
- **Indications for Flaps**
  - Reconstruction: replaces tissue loss due to trauma or surgery
  - Provides skin and temporary soft tissue coverage through which surgery can be carried out later
  - Improves blood supply to poorly vascularized bed (e.g. bone)
- **Complications:** flap loss due to hematoma, seroma, infection, poor flap design, extrinsic compression (dressing too tight) or vascular failure/thrombosis, fat necrosis (in free flaps)
Random Pattern Flaps (see Figure 15)
- blood supply by dermal and subdermal plexus to skin and subdermal tissue with random vascular supply
- limited length:width ratio to ensure adequate blood supply (typically 2:1)
- flap choice is often a combination of available tissue, location of reconstruction site with respect to donor site, and surgeon preference
- types
  - rotation: cover wounds of various sizes; common use: sacral pressure sores
  - transposition: smaller in size compared to rotation flaps and advancement flaps; commonly used on certain areas of the face using adjacent areas of excess skin laxity
  - Z-plasty: used to reorient a scar, lengthen the line of a scar or to break up a scar
  - advancement flaps (V-Y, Y-V)
    - single/bipedicle V-Y flaps: wounds with lax surrounding tissue; the pedicle is the deep tissue underlying the flap

Axial Pattern Flaps (Arterialized)
- flap contains a well defined artery and vein
- allows greater length:width ratio (5-6:1)
- types
  - peninsular flap: skin and vessel intact in pedicle (see Figure 16)
  - island flap: vessel intact, pedicle is better defined (see Figure 17)
  - free flap: vascular supply anastomosed at recipient site by microsurgical techniques
- can be sub-classified according to tissue content of flap:
  - e.g. musculocutaneous/myocutaneous (e.g. transverse rectus abdominal myocutaneous) vs. fasciocutaneous

Free Flaps
- transplanting expendable donor tissue from one part of the body to another by isolating and dividing a dominant artery and veins to a flap and performing a microscopic anastomosis between these and the vessels in the recipient wound
- survival rates >95%
- types: muscle and skin (common), bone, jejunum, omentum
  - e.g. radial forearm, scapular, latissimus dorsi

# Soft Tissue Infections

## Table 13. Classification of Soft Tissue Infections by Depth

<table>
<thead>
<tr>
<th>Infection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Erysipelas</td>
<td>Superficial with subcutaneous tissue involvement</td>
</tr>
<tr>
<td>Cellulitis</td>
<td>Full thickness with subcutaneous tissue involvement</td>
</tr>
<tr>
<td>Fasciitis</td>
<td>Fascia</td>
</tr>
<tr>
<td>Myositis</td>
<td>Muscle</td>
</tr>
</tbody>
</table>

## Erysipelas

**Definition**
- acute skin infection that is more superficial than cellulitis

**Etiology**
- typically caused by Group A β-hemolytic *Streptococcus*

**Clinical Features**
- intense erythema, induration, and **sharply demarcated borders** (differentiates it from other skin infections)

**Treatment**
- penicillin or first generation cephalosporin (e.g. cefazolin or cephalexin)

## Cellulitis

**Definition**
- non-suppurative infection of skin and subcutaneous tissues

**Etiology**
- skin flora most common organisms: *S. aureus*, β-hemolytic *Streptococcus*
- immunocompromised: Gram-negative rods and fungi

**Clinical Features**
- source of infection
  - trauma, recent surgery
  - PVD, diabetes – cracked skin in feet/toes
  - foreign bodies (IV, orthopaedic pins)
- systemic symptoms (fever, chills, malaise)
- pain, tenderness, edema, erythema with poorly defined margins, regional lymphadenopathy
- can lead to ascending lymphangitis (visible red streaking in skin proximal to area of cellulitis)

**Investigations**
- CBC, blood cultures
- culture and Gram stain wound/aspirate from wound if open wound
- plain radiographs if suspect foreign body or abscess
  - r/o bone invasion (osteomyelitis)

**Treatment**
- antibiotics: first line – cephalexin 500 mg PO q6h or cloxacillin 500 mg PO q6h x 7 d; if complicated (e.g. lymphangitis, DM) consider IV cefazolin 1-2 g q8h
- outline area of erythema to monitor success of treatment
- immobilize and splint (hands)

## Necrotizing Fasciitis

**Definition**
- rapidly spreading, very painful infection of the deep fascia with necrosis of tissues
- some bacteria create gas that can be felt as crepitus and be seen on x-rays
- infection spreads rapidly along deep fascial plane and is **limb and life threatening**

**Etiology**
- Type I: polymicrobial (less aggressive)
- Type II: monomicrobial, usually β-hemolytic *Streptococcus*
Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema, edema, tenderness, ± crepitus (subcutaneous gas from anaerobes) ± fever
- infection spreads very rapidly
- patients may look deceptively well at first, but may rapidly become very sick/toxic
- late findings:
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of bullae
  - cutaneous gangrene, subcutaneous emphysema

Investigations
- a clinical diagnosis
- CT scan only if suspect it is not necrotizing fasciitis (looking for abscess, myonecrosis, etc.)
- severely elevated CK: usually means myonecrosis (late sign)
- hemostat easily passed along fascial plane; fascial biopsy to rule out in equivocal situations

Treatment
- rigorous resuscitation (ABCs)
- urgent surgical debridement: remove all necrotic tissue, copious irrigation
- IV antibiotics: as appropriate for clinical scenario; consider penicillin 4 million IU IV q4h or clindamycin 900 mg IV q6h until final cultures available
- urgent consultation with infectious disease specialist is recommended

Ulcers

Lower Limb Ulcers

Traumatic Ulcers (Acute)
- failure of lesions to heal, usually due to compromised blood supply and unstable scar
- usually over bony prominence ± edema ± pigmentation changes ± pain
- treatment: debridement of ulcer and compromised tissue, left to heal via secondary intention with dressings, may need reconstruction with local or distant flap in select cases, vascular status of limb must be assessed clinically and via vascular studies (i.e. sonographically)

Non-Traumatic Ulcers (Chronic)

Pressure Ulcers

Common Sites
- over bony prominences; 95% on lower body

Stages of Development
1. hyperemia: disappears 1 h after pressure removed
2. ischemia: follows 2-6 h of pressure
3. necrosis: follows >6 h of pressure
4. ulcer: necrotic area breaks down – N.B. skin is like tip of an iceberg

Classification (National Pressure Ulcer Advisory Panel 2007)
Stage I: nonblanchable erythema present >1 h after pressure relief, skin intact
Stage II: partial-thickness skin loss
Stage III: full-thickness skin loss into subcutaneous tissue, but not through fascia
Stage IV: through fascia into muscle, bone, tendon, or joint
  ▪ if an eschar is present, must fully debride before staging possible

Prevention
- good nursing care (clean dry skin, frequent repositioning), special beds or mattress (Kin Air®), proper nutrition, activity, early identification of individuals at risk (e.g. immobility, incontinence, paraplegia, etc.)

Treatment
- depends on individual patient and condition
- treat underlying medical issues including nutrition
- continue with preventative measures (pressure relief)
- wound debridement, moisture retentive or antimicrobial dressing, regular reassessment
- topical antimicrobials at treating physician’s discretion, systemic antibiotics for infections
- assess for possible reconstruction

Complications
- cellulitis, osteomyelitis, sepsis, gangrene

Burns

Burn Injuries

Causal Conditions
- thermal (flame contact, scald)
- chemical
- radiation (UV, medical/therapeutic)
- electrical

Most Common Etiology
- children: scald burns
- adults: flame burns

</tbody>
</table>
Pathophysiology of Burn Wounds

- amount of tissue destruction is based on temperature, time of exposure, and specific heat of the causative agent (see Figure 18)
- **zone of hyperemia**: vasodilation from inflammation; entirely viable, cells recover within 7 d; contributes to systemic consequences seen with major burns
- **zone of stasis (edema)**: decreased perfusion; microvascular sludging and thrombosis of vessels results in progressive tissue necrosis → cellular death in 24-48 h without proper treatment
  - factors favoring cell survival: moist, aseptic environment, rich blood supply
  - zone where appropriate early intervention has most profound effect in minimizing injury
- **zone of coagulation (ischemia)**: no blood flow to tissue → irreversible cell damage → cellular death/necrosis

Diagnosis and Prognosis

- burn size (see Figure 19)
  - % of TBSA burned: rule of 9s for 2° and 3° burns only (children <10 yr old use Lund-Browder chart – see Figure 20)
  - for patchy burns, surface area covered by patient’s palm (fingers closed) represents approximately 1% of TBSA
- age: more complications if <3 or >60 yr old
- depth: difficult to assess initially – history of etiologic agent and time of exposure helpful (see Table 16)
- location: face and neck, hands, feet, perineum are critical areas requiring special care of a burn unit (see Indications for Transfer to Burn Centre, PL18)
- inhalation injury: can severely compromise respiratory system
- associated injuries (e.g. fractures)
- co-morbid factors (e.g. concurrent disability, alcoholism, seizure disorders, chronic renal failure) can exacerbate extent of injury

![Figure 19. Rule of 9s for TBSA](image)

</table>

American Burn Association Criteria

- total 2° and 3° burns >10% TBSA
- burns involving the face, hands, feet, genitalia, perineum, or major joints
- 3° burns in any age group
- electrical burns, including lightning (internal injury underestimated by TBSA)
- chemical burns
- inhalation injury (may lead to respiratory distress)
- burns associated with major trauma/serious illness
- burned children in hospitals without appropriate child burn care
- burns in patients who will require special social, emotional, or rehabilitative intervention.

Acute Care of Burn Patients

- adhere to ATLS protocol
- resuscitation using Parkland formula to restore plasma volume and cardiac output
  - 4 cc R/L/kg/% TBSA over first 24 h (1/2 within first 8 h of sustaining burn, 1/2 in next 16 h)
• extra fluid administration required if
  - burn >80% TBSA
  - 4\textdegree\ burns
  - associated traumatic injury
  - electrical burn
  - inhalation injury
  - delayed start of resuscitation
  - pediatric burns
• monitor resuscitation
  - urine output is best measure: maintain at >0.5 cc/kg/h (adults) and 1.0 cc/kg/h (children <12 yr)
  - maintain a clear sensorium, HR <120/min, MAP >70 mmHg
• burn specific care
  - relieve respiratory distress: intubation and/or escharotomy (see sidebar)
  - prevent and/or treat burn shock: 2 large bore IVs
  - identify and treat immediate life-threatening conditions (e.g. inhalation injury, CO poisoning)
  - determine TBSA affected first, since depth is difficult to determine initially (easier to determine after 24 h)
• tetanus prophylaxis if needed
  - all patients with burns >10% TBSA, or deeper than superficial partial thickness, need 0.5 cc tetanus toxoid
  - also give 250 U of tetanus Ig if prior immunization is absent/unclear, or the last booster >10 yr ago
• baseline laboratory studies (Hb, UA, BUN, CXR, electrolytes, ECG, cross-match, ABG, carboxyhemoglobin)
• cleanse, debride, and treat the burn injury (antimicrobial dressings)
• early excision and grafting important for outcome

Respiratory Problems
• 3 major causes
  - burn eschar encircling chest
    - distress may be apparent immediately
  - perform escharotomy to relieve constriction
  - CO poisoning
    - may present immediately or later
    - treat with 100% O\textsubscript{2} by facemask (decreases half-life of carboxyhemoglobin from 210 to 59 min) until carboxyHb <10%
  - smoke inhalation leading to pulmonary injury
    - chemical injury to alveolar basement membrane and pulmonary edema (insidious onset)
    - risk of pulmonary insufficiency (up to 48 h) and pulmonary edema (48-72 h)
    - watch for secondary bronchopneumonia (3-25 d) leading to progressive pulmonary insufficiency
    - intubate patient with any signs of inhalation injuries

Burn Wound Healing

Table 17. Burn Shock Resuscitation (Parkland Formula)

<table>
<thead>
<tr>
<th>Time</th>
<th>Fluid Administration</th>
<th>Notes</th>

Table 18. Burn Wound Healing

<table>
<thead>
<tr>
<th>Depth</th>
<th>Healing</th>
</tr>
</thead>
<tbody>
<tr>
<td>First degree</td>
<td>No scarring. Complete healing</td>
</tr>
<tr>
<td>Second degree (Superficial partial)</td>
<td>Spontaneously re-epithelialize in 7 to 14 d from retained epidermal structures ± residual skin discolouration Hypertrophic scarring uncommon. Grafting rarely required</td>
</tr>
<tr>
<td>Deep second degree (Deep partial)</td>
<td>Re-epithelialize in 14-35 d from retained epidermal structures Hypertrophic scarring frequent Grafting recommended to expedite healing</td>
</tr>
<tr>
<td>Third degree (Full thickness)</td>
<td>Re-epithelialize from the wound edge Grafting flap necessary to replace dermal integrity, limit hypertrophic scarring</td>
</tr>
<tr>
<td>Fourth degree</td>
<td>Often results in amputations</td>
</tr>
</tbody>
</table>

If not requiring amputation, needs flap for coverage after debridement (do not reepithelialize – cannot graft)
Treatment
- 3 stages
  1. assessment: depth determined
  2. management: specific to depth of burn and associated injuries
  3. rehabilitation
- first degree
  - treatment aimed at comfort
    - topical creams (pain control, keep skin moist) ± aloe
    - oral NSAIDs (pain control)
- superficial second degree
  - daily dressing changes with topical antibiotics, polyporous, may use a temporary biological or synthetic covering to close the wound; leave blisters intact unless circulation impaired or unless over joint inhibiting motion
- deep second degree and third degree
  - prevent infection and sepsis (significant cause of death in burn patients)
  - most common organisms: S. aureus, P. aeruginosa and C. albicans
    - day 1-3 (rare): Gram-positive
    - day 3-5: Gram-negative (Proteus, Klebsiella)
  - topical antimicrobials: prevent bacterial infection (from skin flora, gut flora or caregiver) and secondary sepsis (see Table 19)
  - remove dead tissue
  - surgically debride necrotic tissue, excise to viable (bleeding) tissue

Other Considerations in Burn Management

Table 19. Topical Antibiotic Therapy for Burns

<table>
<thead>
<tr>
<th>Antibiotic</th>
<th>Penetration</th>
<th>Adverse Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Silver nitrate (0.5% solution)</td>
<td>None</td>
<td>Minimal, may cause methemoglobinemia, stains (black), leaches sodium from wounds</td>
</tr>
<tr>
<td>Nanocrystalline silver-coated dressing (Acticoat®)</td>
<td>None or transient</td>
<td>Medium, does not penetrate eschar. Preferred over silver sulfadiazine and silver nitrate</td>
</tr>
<tr>
<td>Silver sulfadiazine (cream) (Silvadene®)</td>
<td>Minimal</td>
<td>Medium, does not penetrate eschar. Slowed healing, leukopenia, mild inhibition of epithelialization</td>
</tr>
<tr>
<td>Mafenide acetate (solution/cream) (Sulfamylon®)</td>
<td>Moderate</td>
<td>Well, penetrates eschar. Mild inhibition of epithelialization, may cause metabolic acidosis with wide application</td>
</tr>
</tbody>
</table>

- early excision and grafting is the mainstay of treatment
- initial dressing should decrease bacterial proliferation
- indication for skin graft: deep 2° or 3° burn that is > size of a quarter
- prevention of wound contractures: pressure dressings, joint splints, early physiotherapy

Other Considerations in Burn Management

Vascular Permeability and Edema

Immunosuppression

Renal Failure (2° to ↓ Renal Blood Flow)

- Increased Gut Mucosal Permeability (GI Bleed Risk)
- Progressive Pulmonary Insufficiency
- Hypermetabolism
- Altered Hemodynamics (↓ CO, ↑ SVR)

Risk Factors for Infection of Burn Wounds

Patient Related
- Extent: >30% TBSA
- Depth: full-thickness and deep partial-thickness
- Patient age (higher risk with very young and very old)
- Co-morbidities
- Wound dryness
- Wound temperature
- Secondary impairment of blood flow to wound
- Acidosis

Microbial Factors
- Density >10^6 organisms per gram tissue
- Motility
- Virulence and metabolic products (endotoxin, exotoxin, permeability factors, other factors)
- Antimicrobial resistance

Figure 21. Systemic effects of severe burns
- nutrition
  - hypermetabolism: TBSA >40% have BMR 2-2.5x predicted
  - calories, vitamin C, vitamin A, Ca^2+, Zn^2+, Fe^2+
- immunosuppression and sepsis
  - must keep bacterial count <10^8 bacteria/g of tissue (blood culture may not be positive)
  - signs of sepsis: sudden onset of hyper/hypothermia, unexpected CHF or pulmonary edema, development of ARDS, ileus >48 h post-burn, mental status changes, azotemia, thrombocytopenia, hypofibrinogenemia, hyper/hypoglycemia (especially if burn >40% TBSA)
- GI bleed may occur with burns >40% TBSA (usually subclinical)
  - treatment: tube feeding or NPO, antacids, H2 blockers (preventative)
- renal failure secondary to under resuscitation, drugs, myoglobin, etc.
- progressive pulmonary insufficiency
  - can occur after: smoke inhalation, pneumonia, cardiac decompensation, sepsis
- wound contracture and hypertrophic scarring
  - largely preventable with timely wound closure, splinting, pressure garments and physiotherapy

Meta-Analysis of Early Excision of Burns 2006;32:145-150
Purpose: To determine if early excision and grafting is superior (or equivalent) to conservative treatment and delayed grafting once the burn eschar has separated.
Methods: A literature review was completed seeking prospective randomized controlled trials comparing early excision (<7 d) and immediate grafting against treatment with dressings followed by grafting post-eschar separation. All ages and burn severities were included. Outcomes were mortality, blood transfusions, wound healing time and length of hospital stay.
Results: A total of 361 patients from 7 randomized controlled trials were included in the meta-analysis. 180 patients received early intervention and 181 received conservative management. There was no significant difference in mortality in patients with inhalational injury. Early excision and grafting in patients without inhalational injury resulted in significantly reduced mortality (RR 0.36, p<0.05) and decreased length of hospitalization by 0.09 d (p<0.05). The number of patients requiring blood transfusion was significantly higher with early excisional management (SMD 1.85, p<0.05). There was no significant difference in wound healing time between the two groups.
Conclusion: Early excision of burns (<7 d) is beneficial in reducing mortality in patients without inhalational injury, along with reducing length of time spent in hospital.

Figure 19. Flowchart of work up and treatment of burns

Figure 20. Tissue physiology of burn wounds
Special Considerations

CHEMICAL BURNS
- major categories: acid burns, alkaline burns, phosphorous burns, chemical injection injuries
- common agents: cement, hydrofluoric acid, phenol, tar
- mechanism of injury: chemical solutions coagulate tissue protein leading to necrosis
  - acids → coagulation necrosis
  - alkalines → saponification followed by liquefactive necrosis
- severity related to: type of chemical (alkali worse than acid), temperature, volume, concentration, contact time, site affected, mechanism of chemical action, degree of tissue penetration
- burns are deeper than they initially appear and may progress with time

Treatment (general)
- ABCs, monitoring
- remove contaminated clothing and brush off any dry powders before irrigation
- irrigation with water for 1-2 h under low pressure (contraindicated in heavy metal burns, such as sodium, potassium, magnesium, and lithium; in these cases soak in mineral oil instead)
- inspect eyes, if affected: wash with saline and refer to ophthalmology
- inspect nails, hair and webspaces
- correct metabolic abnormalities and tetanus prophylaxis if necessary
- local wound care 12 h after initial dilution (debridement)
- wound closure same as for thermal burn
- beware of underestimated fluid resuscitation, renal, liver, and pulmonary damage

ELECTRICAL BURNS
- depth of burn depends on voltage and resistance of the tissue (injury more severe in tissues with high resistance)
- often presents as small punctate burns on skin with extensive deep tissue damage which requires debridement
- electrical burns require ongoing monitoring as latent injuries can occur
- watch for system specific damages and abnormalities:
  - abdominal: intraperitoneal damage
  - bone: fractures and dislocations especially of the spine and shoulder
  - cardiopulmonary: anoxia, ventricular fibrillation, arrhythmias
  - muscle: myoglobinuria indicates significant muscle damage → compartment syndrome
  - neurological: seizures and spinal cord damage
  - ophthalmology: cataract formation (late complication)
  - renal: ATN resulting from toxic levels of myoglobin and hemoglobin
  - vascular: vessel thrombosis → tissue necrosis (increased Cr, K⁺ and acidity), decrease in RBC (beware of hemorrhages/delayed vessel rupture)

Treatment
- ABCs, primary and secondary survey, treat associated injuries
- monitor: hemochromogenuria, compartment syndrome, urine output
- wound management: topical agent with good penetrating ability (silver sulfadiazine or mafenide acetate)
- debride non-viable tissue early and repeat prn (every 48 h) to prevent sepsis
- amputations frequently required

FROSTBITE
- see Emergency Medicine, ER45
Table 20. Key Features of the History and Physical Exam of the Injured Hand in the Emergency Department

| HISTORY | | 
| Key Questions | Age | Hand dominance | Occupation | Time and place of accident | Mechanism of injury | Tetanus status |

| PHYSICAL EXAM | Structure | Examination |
| Position of finger | Abnormal cadence (fingers normally slightly flexed), scissoring |
| Deformity | Bony or specific (e.g., mallet, swan neck) |
| Bruising or swelling | May indicate underlying skeletal injury |
| Sweating pattern | May indicate denervation |
| Anatomical structures beneath | If open laceration, need to explore within wound (under sterile conditions) |

| Vascular Status | Radial and ulnar arteries | Allen's Test (see sidebar) |
| Digital arteries | Capillary refill (<2-3 s) |
| Temperature and skin turgor | For each test, need to compare both sides |

| Sensory (refer to Figure 3) | Median nerve | Dorsal radial tip of index finger |
| Ulnar nerve | Dorsal ulnar tip of little finger |
| Radial nerve | Dorsal web space of the thumb |
| Digital nerves | 2 point discrimination of each finger |

| Motor Function | Median nerve | Extrinsic muscles: flex DIP of index finger ("OK sign") |
| Intrinsic muscles: thumb to ceiling with palm up |
| Ulnar nerve | Extrinsic muscles: flex DIP of little finger Intrinsic muscles: abduct index finger ("Peace sign") or patient able to hold piece of paper between adducted fingers and resist pulling |
| Radial nerve | Extrinsic muscles: extend thumb ("thumb's up") and wrist |

| Range of Motion | Tendons, bones, joints, nerves | Assess active and passive range of motion of wrist extension/flexion/ulnar/radial deviation, finger abduction/adduction/flexion/extension, thumb flexion/extension/abduction/adduction/circumflexion |

| Tendons | Flexor digitorum profundus (FDP) | Stabilize PIP joint in extension, ask patient to flex fingers (at DIP) (see Figure 22) |
| Flexor digitorum superficialis (FDS) | Stabilize non-exam fingers in extension (neutralizes FDP) and ask patient to flex examination finger (see Figure 23) |

| Palpation | Bones | Focal tenderness or abnormal alignment |
| Joints | Instability may indicate ligamentous injury or dislocation |

General Management

Nerves
- direct repair for a clean injury within 14 d and without concurrent major injuries → otherwise secondary repair
- epineural repair of digital nerves with minimal tension
- post-operative: dress wound, elevate hand and immobilize
- Tinel's sign (cutaneous percussion over the repaired nerve) produces paresthesias and defines level of nerve regeneration
  - Wallerian degeneration occurs in the first 2 wk, which is why there is no Tinel's sign till after this time period
  - a peripheral nerve regenerates at 1 mm/d
  - paresthesias felt at area of percussion because re-growth of myelin (Schwann cells) is slower than axonal re-growth → percussion on exposed free-end of axon generates paresthesia
Vessels
- often associated with nerve injury (anatomical proximity)
- control bleeding with direct pressure and hand elevation
- if digit devascularized, optimal repair within 6 h
- dress, immobilize, and splint hand with finger tips visible
- monitor colour, capillary refill, skin turgor, fingertip temperature post-revascularization

Tendons
- most tendon lacerations require primary repair
- many extensors are repaired in the emergency room, flexors are repaired in the operating room within 2 wk
- avoid excessive immobilization (specific protocols for flexors, 2-3 wk for extensors) to minimize stiffness and facilitate rehabilitation

Bones
- see Fractures and Dislocations, PL25

Nailbed
- remove nail to examine underlying nailbed under digital block anesthesia
- irrigate wound and nail thoroughly
- suture repair of nailbed with catgut suture
- replace cleaned nail, which acts as splint for any underlying distal phalangeal fracture and prevents adhesion formation between nail fold and nailbed

Hand Infections

Principles
- trauma is most common cause
- 5 cardinal signs: rubor (red), calor (hot), tumour (swollen), dolor (painful) and functio laesa (loss of function)
- 90% caused by Gram-positive organisms
- most common organisms (in order) – S. aureus, S. viridans, Group A Streptococcus, S. epidermidis, and Bacteroides melaninogenicus (MRSA becoming more common)

TYPES OF INFECTIONS

Deep Palmar Space Infections
- uncommon, involve thenar or mid-palm, treated in OR

Felon
- definition: subcutaneous abscess in the fingertip that commonly occurs following severe paronychia or a puncture wound into the pad of digit; may be associated with osteomyelitis
- treatment: elevation, warm soaks, cloxacillin 500 mg PO q6h (if in early stage); if obvious abscess then I&D and PO cloxacillin

Flexor Tendon Sheath Infection
- \textit{Staphylococcus} > \textit{Streptococcus} > Gram-negative rods
- definition: acute suppurative tenosynovitis commonly caused by a penetrating injury and can lead to tendon necrosis and rupture if not treated
- clinical features: Kanavel’s 4 cardinal signs:
  1. point tenderness along flexor tendon sheath (earliest and the most important)
  2. severe pain on passive extension of DIP (second most important)
  3. fusiform swelling of entire digit
  4. flexed posture (increased comfort)
- treatment
  - OR incision and drainage, irrigation, IV antibiotics, and resting hand splint until infection resolves

Herpetic Whitlow
- HSV-1, HSV-2
- definition: painful vesicle(s) around fingertip
  - often found in medical/dental personnel and children
- clinical features: can be associated with fever, malaise and lymphadenopathy
  - patient is infectious until lesion has completely healed
- treatment: routine culture and viral prep protection (cover), consider oral acyclovir; do not break blisters, as this can spread infection

Paronychia
- acute = \textit{Staphylococcus}; chronic = \textit{Candida}
- definition: infection (granulation tissue) of soft tissue around fingernail (beneath eponychial fold)
• **etiology**  
  - acute paronychia: a “hangnail”, artificial nails, and nail biting  
  - chronic paronychia: prolonged exposure to moisture  
• **treatment**  
  - acute paronychia: warm compresses and cephalaxin 500 mg PO q6h ± drainage if abscess present  
  - chronic paronychia: anti-fungals with possible debridement and marsupialization, removal of nail plate

### Amputations

**Hand or Finger**  
- emergency management: injured patient and amputated part require attention  
  - **patient**: x-rays, NPO, clean wound and irrigate with NS, dress stump with nonadherent, cover with dry sterile dressing, tetanus and antibiotic prophylaxis (cephalosporin/erythromycin)  
  - **amputated part**: x-rays, gently irrigate with RL, wrap amputated part in a NS/RL soaked sterile gauze and place inside waterproof plastic bag, place in a container, then place container on ice

- **indications for replantation**  
  - **age**: children often better results than adults  
  - **level of injury**: proximal, thumb and multiple digit amputations are higher priority  
  - **nature of injury**: clean cut injuries have higher successful replantation rate; avulsion and crush injuries are relative contraindications to replant  
- if replant contraindicated manage stump with revision amputation  
  - would only allow a fingertip injury to heal by secondary intention

### Tendons

**Common Extensor Tendon Deformities**

<table>

  Consider arthrodesis/arthroplasty |

**De Quervain’s Tenosynovitis (zone 7; most common cause of radial wrist pain)**  
- **definition**: inflammation in 1st extensor compartment (APL and EPB)  
- **clinical features**:  
  - +ve Finkelstein’s test (pain over the radial styloid induced by making fist, with thumb in palm, and ulnar deviation of wrist)  
  - pain localized to the 1st extensor compartment  
  - tenderness and crepitant over radial styloid may be present  
  - differentiate from CMC joint arthritis (CMC joint arthritis will have a positive grind test, whereby crepitus and pain are elicited by axial pressure to the thumb)  
- **treatment**:  
  - mild: NSAIDs, splinting and steroid injection into the tendon sheath (successful in over 60% of cases)  
  - severe: surgical release of stenotic tendon sheaths (APL and EPB); remember there may be 2 or more sheaths

**Ganglion Cyst (zone 7)**  
- **definition**:  
  - fluid-filled synovial lining that protrudes between carpal bones or from a tendon sheath; most commonly carpal in origin  
  - most common soft tissue tumour of hand and wrist (60% of masses)  

---

[Images and diagrams are not transcribed.]
• **clinical features:**
  - most common around scapholunate ligament junction
  - 3 times more common in women than in men
  - more common in younger individuals
  - can be large or small – may drain internally so size may wax and wane
  - often non-tender although tenderness increased when cyst smaller (from increased pressure within smaller cyst sac)

• **treatment:**
  - conservative treatment: watch and wait
  - aspiration (recurrence rate 65%)
  - consider operative excision of cyst and stalk (recurrence is possible)
  - steroids if painful

**Common Flexor Tendon Deformities** (see Figure 28)

• flexor tendon zones (important for prognosis of tendon lacerations)
  - “no-man’s land”:
    - between distal palmar crease and mid-middle phalanx
    - zone where superficialis and profundus lie enmeshed together
    - recovery of glide very difficult after injury

**Stenosing Tenosynovitis (trigger finger/thumb)**

• **definition:** inflammation of synovium causes size discrepancy between tendon and sheath/pulley (most commonly at A-1 pulley) = locking of thumb or finger in flexion/extension

• **etiology:** idiopathic or associated with RA, diabetes, hypothyroidism and gout

• **clinical features:**
  - thumb, ring and long fingers most commonly affected
  - patient complains of catching, snapping or locking of affected finger
  - tenderness to palpation/nodule at palmar aspect of MCP over A-1 pulley
  - women are 4 times more likely than men to be affected

• **conservative treatment:**
  - NSAIDs
  - steroid injection
  - surgical flexor tendon release
  - injections less likely to be successful in patients with DM or symptoms greater than 6 mo

• **surgical treatment:**
  - incise A-1 flexor tendon pulley to permit unrestricted, full active finger motion

**Fractures and Dislocations**

• for fracture principles, see [Orthopedics, OR5](#)

**FRACTURES**

• about 90% of hand fractures are stable in flexion (lock/prevent extension)

• **position of function** (like a hand holding a pop can) (see Figure 29):
  - wrist extension 15°
  - MCP flexion 45°
  - IP flexion (slight)
  - thumb abduction/rotation
  - contraindications: post repair of flexor tendons, median/ulnar nerve injury

• **position of safety** (see Figure 30):
  - wrist extension 45° (position most beneficial for hand function if immobilized)
  - MCP flexion 60° (maximal collateral ligament stretch)
  - PIP and DIP in full extension (maximal volar plate origin stretch)
  - thumb abduction and opposition (functional position)
  - stiffness secondary to immobilization is the most important complication; Tx = early motion

**Distal Phalanx Fractures**

• most commonly fractured bone in the hand

• usual mechanism is crush injury and thus accompanied by soft tissue injury

• subungual hematoma is common and must be decompressed if painful or nail removed

• treatment consists of 3 wk of digital splinting (with IP joint movement preserved)

**Proximal and Middle Phalanx Fractures**

• check for: rotation, scissoring (overlap of fingers on making a fist), shortening of digit

• undisplaced or minimally displaced: closed reduction (if extra-articular) buddy tape to neighbouring stable digit, elevate hand, motion in guarded fashion 10-14 d post injury

• displaced, non-reducible, not stable with closed reduction, or rotational or scissoring deformity: percutaneous pins (K-wires) or ORIF, and splint
Metacarpal Fractures

- generally accept varying degrees of deviation before reduction required: up to 10° (D2), 20° (D3), 30° (D4), or 40° (D5)
- **Boxer's fracture (extra-articular):** acute angulation of neck of metacarpal of little finger into palm (see Figure 31)
  - mechanism: blow on the distal-dorsal aspect of closed fist
  - loss of prominence of metacarpal head, volar displacement of head
  - check for scissoring of fingers on making a fist
  - up to 30-40° angulation may be acceptable
  - closed reduction should be considered to decrease the angle
  - if stable ulnar gutter splint x 3 wk with PIP and DIP joints free
- **Bennett's fracture (intra-articular):** fracture/dislocation of the base of the thumb metacarpal (see Figure 32)
  - unstable fracture
  - abductor pollicis longus pulls MC shaft proximally and radially causing adduction of thumb
  - treat with percutaneous pinning, thumb spica x 6 wk
- **Rolando's fracture (intra-articular):** T- or Y-shaped fracture of the base of the thumb metacarpal (see Figure 33)
  - treat with ORIF with K-wire

**DISLOCATIONS**

- must be reduced as soon as possible

**PIP and DIP Dislocations (PIP more common than DIP)**

- usually dorsal dislocation (commonly from hyperextension)
- if closed dislocation: closed reduction and splinting (30° flexion for PIP and full extension for DIP) or buddy taping and early mobilization (prolonged immobilization causes stiffness)
- open injuries are treated with wound care, closed or open reduction and antibiotics

**MCP Dislocations (relatively rare)**

- dorsal dislocations much more common than volar dislocations
- dorsal dislocation of proximal phalanx on metacarpal head; most commonly index finger (hyperextension)
- two types of dorsal dislocation:
  - simple (reducible with manipulation): treat with 2 wk of splinting at 30° MCP flexion
  - complex (volar plate blocks reduction): treat with open reduction and A1 pulley release + extension-blocking splint at 30° flexion (2 wk) then 10° flexion (2 wk)

**Ulnar Collateral Ligament (UCL) Injury**

- forced abduction of thumb (e.g. ski pole injury)
- **skier's thumb:** acute UCL injury
- **gamekeepers thumb:** chronic UCL injury
- **evaluation:** radially deviate joint in full extension and at 30° flexion and compare with non-injured hand. UCL rupture is presumed if injured side deviates more than 30° in full extension or more than 15° in flexion
- **Stener's lesion:** the UCL has bony attachments to the adductor aponeurosis and the proximal ligament can displace while the distal attachment remains deep to the aponeurosis, forming a barrier that blocks healing and leads to chronic instability; requires surgery

**Dupuytren’s Disease**

**Definition**

- contraction of longitudinal palmar fascia, forming nodules (usually painless), fibrous cords and eventually flexion contractures at the MCP and interphalangeal joints (see Figure 34)
- flexor tendons not involved
- Dupuytren's diathesis: early age of onset, strong family history, and involvement of sites other than palmar aspect of hand

**Epidemiology**

- genetic disorder, unusual in patients from African and Asian countries, high incidence in northern Europeans, men > women, often presents in 5th-7th decade of life, associated with but not caused by alcohol use and diabetes

**Clinical Features**

- order of digit involvement (most common to least common): ring > little > long > thumb > index
- may also involve feet (Lederhosen’s) and penis (Peyronie’s – see *Urology*, U29)
Clinical Features

- Investigations
  - indications for percutaneous release:
    - functional impairment
    - MCP joint contractures >30°
    - any PIP contracture
    - rapidly progressive disease
  - may recur, especially in Dupuytren's diathesis

Surgical Treatment of Common Problems

- General Principles
  - non-surgical treatments form the foundation in the management of the rheumatoid hand
  - surgery only for patients whose goals (improved cosmesis or function) may be achieved

Rheumatoid Hand

General Principles

- non-surgical treatments form the foundation in the management of the rheumatoid hand
- surgery only for patients whose goals (improved cosmesis or function) may be achieved

Surgical Treatment of Common Problems

- synovitis: requires tendon repair if ruptured; can lead to carpal tunnel syndrome and trigger finger
- ulnar drift: MCP arthroplasty, resection of distal ulna, soft tissue reconstruction around wrist
- thumb deformities: can be successfully treated by arthrodesis (surgical fixation of joint to promote bone fusion)

Carpal Tunnel Syndrome

Definition

- median nerve compression at the level of the flexor retinaculum as opposed to pronator teres syndrome

Etiology

- median nerve entrapment at wrist
- primary cause is idiopathic
- secondary causes: space occupying lesions (tumours, hypertrophic synovial tissue, fracture callus, and osteophytes), metabolic and physiological (pregnancy, hypothyroidism, acromegaly, and RA), infections, neuropathies (associated with DM or alcoholism), and familial disorders
- job/hobby repetitive trauma, especially forced wrist flexion

Epidemiology

- female: male = 4:1, most common entrapment neuropathy

Clinical Features

- sensory loss in median nerve distribution i.e. radial 3.5 digits (see Figure 3)
- discriminative touch often lost first
- classically, patient awakened at night with numb/painful hand, relieved by shaking/dangling/rubbing
- decreased light touch and 2-point discrimination, especially fingertips
- advanced cases: thenar wasting/weakness
- ± Tinel's sign (tingling sensation on percussion of nerve)
- ± Phalen's sign (wrist flexion induces symptoms)

Investigations

- clinical diagnosis
- NCV and EMG may confirm, but do not exclude, the diagnosis

Treatment

- avoid repetitive wrist and hand motion, wrist splints when repetitive wrist motion required
- conservative: night time splinting to keep wrist in neutral position
- medical: NSAIDs, local corticosteroids injection, oral corticosteroids
- surgical decompression: transverse carpal ligament incision to decompress median nerve
- indications for surgery: numbness and tingling ± sensory loss, weakness ± muscle atrophy, unresponsive to conservative measures
- complications of surgery: injury to median motor branch, palmar cutaneous branch or superficial transverse vascular arch, local pain (pilar pain), and scar formation

Radiographic Evolution of the Rheumatoid Hand

- Earliest sign: erosion of the ulnar styloid
- Progression: characterized by symmetrical joint space narrowing and erosions of the carpal bones, MCP and PIP (with DIP relatively spared)
- Late stage: Swan neck and Boutonniere deformities

Tests:

- Phalen's test: Sensitivity: 0.75, Specificity: 0.47
- Tinel's test: Sensitivity: 0.60, Specificity: 0.67
- Carpal Tunnel Compression Test: Sensitivity: 0.87, Specificity: 0.90

Results/Conclusions: The correlation between the probability of CTS predicted by the regression model and the panel of clinicians was 0.71. Clinical diagnostic criteria that contributed significantly to the model were:

1. Numbness and tingling in median nerve distribution
2. Nocturnal numbness
3. Weakness and/or atrophy of the thenar musculature
4. Tinel's sign
5. Phalen's test
6. Loss of 2-point discrimination

Accuracy of the Clinical Assessment for Carpal Tunnel Syndrome

- Phalen's:
  - Sensitivity: 0.75, Specificity: 0.47
- Tinel's:
  - Sensitivity: 0.60, Specificity: 0.67
- Carpal Tunnel Compression Test:
  - Sensitivity: 0.87, Specificity: 0.90

Hand Surgery Update 1986; p.223
Brachial Plexus

Etiology
- common causes of brachial plexus injury: complication of childbirth and trauma
- other causes of injury: compression from tumours, ectopic ribs

Common Palsies

Table 22. Named Neonatal Palsies of the Brachial Plexus

<table>
<thead>
<tr>
<th>Palsy</th>
<th>Location of Injury</th>
<th>Mechanism of Injury</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duchenne-Erb Palsy</td>
<td>Upper brachial plexus (C5-C6)</td>
<td>Head/shoulder distraction (e.g. motorcycle)</td>
<td>Waiter’s tip deformity (shoulder internal rotation, elbow extension, wrist flexion)</td>
</tr>
<tr>
<td>Klumpke’s Palsy</td>
<td>Lower brachial plexus (C7-T1)</td>
<td>Traction on abducted arm</td>
<td>May include Horner’s syndrome (“claw hand”)</td>
</tr>
</tbody>
</table>

Differential Diagnosis
- trauma (blunt, penetrating)
- thoracic outlet syndrome
  - neurogenic: associated with cervical rib; compression of C8/T1
  - vascular: pain or sensory symptoms without cervical rib; cessation of radial pulse with provocative maneuvers
- tumour
  - schwannoma: well-defined margins makes it easier for total resection
  - neurofibromas: associated with neurofibromatosis type I
  - other: e.g. Pancoast syndrome (apical lung tumour)
- neuropathy (compressive, post-irradiation, viral, diabetic, idiopathic)

Investigations
- EMG
- MRI: gold standard for identifying soft tissue masses
- CT myelogram: better than MRI for identification of nerve root avulsion and identification of pseudomeningocele. Important for preoperative identification of patients likely to require neurotisation procedures (especially for patients with blunt trauma)

Management

Craniofacial Injuries

- low velocity vs. high velocity injuries determine degree of damage
- fractures cause bruising, swelling and tenderness → loss of function
- frequency: nasal > zygomatic > mandibular > maxillary
- management: can wait 5-10 d for swelling to decrease before ORIF required
Approach to Facial Injuries

- ATLS protocol
- inspect, palpate, clinical assessment for injury to underlying structures (e.g. facial nerve)
- visual assessment
- tetanus prophylaxis
- radiological evaluation
- wound irrigation with NS/RL and remove foreign materials
- conservative debridement of detached or nonviable tissue
- repair when patient's general condition allows (soft tissue injury: <8 h preferable)

Investigations (see Table 24)
- CT:
  - axial and coronal (specifically request 1.5 mm cuts): for fractures of upper and middle face (not good for mandible)
  - indicated for high velocity trauma, complex facial fractures, orbital floor, panface fractures, pre-op assessment
- panorex radiograph: shows entire upper and lower jaw; best for isolated mandible fracture as patient must be able to sit

Table 24. Imaging of the Craniofacial Skeleton

*Best imaging method

Treatment
- consultation when indicated (dentistry, ophthalmology)
- re-establish normal occlusion
- pursue normal eye function
- restore stability of face and appearance

Complications
- diplopia/enophthalmos/blindness
- intracranial pathology such as CSF leak, bleeding and SIADH
- sinusitis
- functional abnormalities (i.e. malocclusion)
- infection – extremely rare
- poor cosmesis; need for 2° surgery

Mandibular Fractures

always two points of injury since it is a ring structure (includes fractures and dislocations)
commonly at sites of weakness (condylar neck, angle of mandible, region of 3rd molar or canine tooth)

Etiology
- anterior force: bilateral fractures
- lateral force: ipsilateral subcondylar and contralateral angle or body fracture
- note: classified as open if fracture into tooth bearing area (alveolus)

Clinical Features
- pain, swelling, difficulty opening mouth (“trismus”)
- malocclusion, asymmetry of dental arch
- damaged, loose, or lost teeth
- palpable “step” along mandible
- numbness in V3 distribution
- intra-oral lacerations or hematoma (sublingual)
- chin deviating toward side of a fractured condyle

Patients with major facial injuries are at risk of developing upper airway obstruction (displaced blood clots, teeth or fracture fragments; swelling of pharynx and larynx; loss of support of hyomandibular complex → retroposition of tongue). Also at risk of ocular injury.

Suspect C-spine injury with any facial trauma. C-spine evaluation before radiographs are ordered.

Consider intracranial trauma; rule out skull fracture.

Signs of Basal Skull Fracture
- Battle’s sign (bruised mastoid process)
- Hemotympanum
- Raccoon eyes (periorbital bruising)
- CSF otorrhea

Facial bone injuries with orbit involved require ophthalmology consult.
Classification

Table 25. Mandibular Fracture Classifications by Anatomic Region (refer to Figure 35)

<table>
<thead>
<tr>
<th>Areas/Boundaries</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symphysis</td>

</tr>
<tr>
<td>Angle</td>
<td>Triangular region between the anterior border of the masseter and the posterosuperior insertion of the masseter distal to the third molar</td>
</tr>
<tr>
<td>Ramus</td>
<td>Part of the mandible that extends posterosuperiorly into the condylar and coronoid processes</td>
</tr>
<tr>
<td>Condylar</td>
<td>Area of condylar process of mandible</td>
</tr>
<tr>
<td>Subcondylar</td>
<td>Area below the condylar neck (i.e. sigmoid notch) of the mandible</td>
</tr>
<tr>
<td>Corooid Process</td>
<td>Area of the coronoid process of mandible</td>
</tr>
</tbody>
</table>

*Most common mandibular fracture type

Treatment
- maxillary and mandibular arch bars wired together (intramaxillary fixation) or ORIF
- antibiotics to cover against *S. aureus* and anaerobes

Complications
- malocclusion, malunion
- tooth loss, and possible sensation loss
- TMJ ankylosis

Maxillary Fractures

</tbody>
</table>

Nasal Fractures

Etiology
- lateral force → more common, good prognosis
- anterior force → can produce more serious injuries
- most common facial fracture

Clinical Features
- epistaxis/hemorrhage, deviation/flattening of nose, swelling, periorbital ecchymosis, tenderness over nasal dorsum, crepitus, septal hematoma, respiratory obstruction, subconjunctival hemorrhage
- depression and splaying of nasal bones causing a saddle deformity
- important to clinically assess for naso-orbital ethmoid (NOE) fractures

Treatment
- in the absence of complications, no treatment required
- closed reduction with Asch or Walsham forceps under anesthesia, pack nostrils with Adaptic®, nasal splint for 7 d
- best reduction immediately (<6 h) or when swelling subsides (5-7 d)
- rhinoplasty may be necessary later for residual deformity (30%)

Always drain septal hematomas as this is a cause of septal necrosis with perforation (saddle nose deformity).
Naso-orbital Ethmoid Fractures

**Etiology**
- fractures of the nasal and ethmoid bones of the medial orbit
- problematic and may lead to greatest change in facial appearance
- Markowitz-Manson classification:
  - Type 1: Single, central fragment, medial canthal ligament intact
  - Type 2: Comminuted central fragment, medial canthal ligament intact
  - Type 3: Severe comminution of central fragment and disrupted medial canthal ligament

**Clinical Presentation**
- telecanthus (increased intercanthal distance secondary to medial canthal ligament disruption)
- orbital rim step-off
- similar to nasal fractures (see Nasal Fractures, PL30)

**Treatment**
- surgical repair to restore intercanthal distance, nasal projection and orbital anatomy

Zygomatic Fractures

- 3 categories (see Figure 37)
  1. fracture restricted to zygomatic arch
  2. depressed fracture of zygomatic complex (zygoma)
  3. unstable fracture of zygomatic complex (tetrapod fracture) – separations occur at maxilla, frontal bone, temporal bone and orbital rim

**Clinical Features**
- flattening of malar prominence (view from above)
- pain over fractures on palpation
- numbness in V2 distribution (infraorbital and superior dental nerves)
- palpable step deformity in bony orbital rim (especially inferiorly)
- often associated with fractures of the orbital floor
- ipsilateral epistaxis; trismus (lock jaw)

**Treatment**
- if undisplaced, stable and no symptoms, then soft diet; no treatment necessary
- ophthalmologic evaluation if suspected orbital injury
- uncomplicated zygomatic arch fractures can be elevated using Gillies approach: leverage on the anterior part of the zygomatic arch via a temporal incision; stabilization often unnecessary
- ORIF for displaced or unstable fractures of zygomatic complex

Orbital Floor Fractures

- see Ophthalmology, OP42

**Definition**
- fracture of floor of orbit ± intact infraorbital rim (see Figure 38)
- may be associated with nasoethmoid fracture

**Etiology**
- blunt force to eyeball → sudden increase in intra-orbital pressure (e.g. baseball or fist)

**Clinical Features**
- check visual fields and acuity for injury to globe
- periorbital edema and bruising, subconjunctival hemorrhage
- ptosis, exophthalmos, exorbitism, or enophthalmos
- orbital rim step-offs with possible infraorbital nerve anesthesia
- vertical dystopia (abnormal displacement of the entire orbital cone in the vertical plane); diplopia looking up or down (entrapment of inferior rectus), limited EOM
- orbital entrapment:
  - clinical diagnosis that is a surgical emergency
  - diplopia with vertical gaze; limited EOM
  - severe pain or nausea and vomiting with eye movement
  - requires urgent ophthalmology evaluation and surgical repair
Investigations
• CT (diagnostic): axial and coronal views
• diagnostic manoeuvre for entrapment is **forced duction** test (pulling on inferior rectus muscle with forceps to ensure full ROM) under anesthesia

Treatment
• surgical repair indicated if: urgent repair for entrapment, floor defect >1 cm, any size defect with enophthalmos or persistent diplopia (>10 d)
• reconstruction of orbital floor with bone graft or alloplastic material
• ophthalmologic evaluation suggested

Complications
• persistent diplopia
• enophthalmos

**Superior Orbital Fissure Syndrome**
• fracture of SOF causing ptosis, proptosis, anesthesia in V1 distribution, and painful ophthalmoplegia (paralysis of CN III, IV, VI)
• uncommon complication seen in Le Fort II and III fractures (1/130)
• recovery time reported as 4.8-23 wk following operative reduction of fractures

**Orbital Apex Syndrome**
• fracture through optic canal with involvement of CN II at apex of orbit
• symptoms are the same as SOF syndrome plus vision loss
• treatment is urgent decompression of fracture in optic canal or steroids (emergency)

**Breast Surgery**

**Breast Reconstruction**

• integral part of breast cancer treatment
• two basic methods: implants (1-stage or 2-stage) or autologous tissue (see Table 27)
• may also require breast balancing procedure and nipple areola reconstruction

**Pre-Reconstruction Considerations**
• radiation: treatment before and after mastectomy is a relative contraindication to alloplastic reconstruction
• recipient tissue: skin sparing mastectomy allows for the use of implants without tissue expanders (1-stage process)
• donor tissue: limited availability of suitable donor tissue (lack of tissue, scar, previous surgery that interferes with blood supply) may prevent the use of autologous tissue reconstruction
• timing (immediate vs. delayed)
• contralateral breast: may not be possible to reconstruct a breast of the same size or shape as the contralateral breast. Breast reduction or mastopexy may be considered in opposite breast (see Table 28)
• other considerations: patient’s age and co-morbidities, prognosis, body weight, characteristics of chest wall and patient’s attitude

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Definition</th>
<th>Surgical Details</th>
<th>Other Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Implant</strong></td>
<td>Use of synthetic material (silicone or saline implants)</td>
<td>With expanders (2 stages): Use tissue expanders before replacement with implants to help facilitate breast ptosis. (see Breast Tissue Expanders, PL33) Without expanders (1 stage): In skin-sparing mastectomy, enough skin is available for immediate placement of implant</td>
<td>Complications: capsular contraction (foreign body reaction to implants), rupture or leakage of implant, increased risk of infection, 35% revision rate over 5 yr</td>
</tr>
<tr>
<td><strong>Autologous Tissue</strong></td>
<td>Use of patient’s own tissue</td>
<td>Many flap options: DIEP, TRAM, latissimus dorsi, SIEA, SGAP, and IGAP</td>
<td>Offers reduced long-term morbidity and natural consistency</td>
</tr>
<tr>
<td><strong>Nipple Areola Reconstruction</strong></td>
<td>Final stage of breast reconstruction</td>
<td>Usually require tattooing for areola reconstruction Local vs. distant flap/graft: 1. Local: fish tail or skate flap most common; these flaps allow simultaneous nipple and areola reconstruction 2. Distant: opposite nipple, earlobe, abdominal skin, costal cartilage, labia</td>
<td>Usually performed 3 mo post-reconstruction</td>
</tr>
</tbody>
</table>

Table 27. Options for Breast Reconstruction
Breast Tissue Expanders

- types: textured vs. smooth, both with integrated port
- placement: sub-pectoral, total submuscular (pectoral/serratus)
- size: depends on contralateral breast and desired size
  - generally over-expanded to facilitate ptosis
- timing of expansion: begins when wound fully healed (usually 2 wk post-op), and implants are expanded weekly or bi-weekly until complete (up to 3 mo). Expanders are exchanged for implants after another 3 mo for consolidation of expanded skin

Breast Reduction

- reduction mammoplasty performed for relief of physical symptoms (e.g. shoulder groove, neck pain, back pain, shoulder pain, mastodynia), and to improve breast size and shape
- key steps of procedure:
  - incisions: circular around the areola, vertical from areola incision to infra-mammary fold, along the natural infra-mammary fold
  - removal of fat, breast tissue, and excess skin
  - possible need to move nipple and areola complex to higher position
- complications: infection, hemorrhage, decreased nipple sensation, inability to breast feed, breast/nipple asymmetry, nipple loss (partial or complete), skin loss/necrosis, fat necrosis

Aesthetic Surgery

### Historical Context of Public Health

See Ethical, Legal and Organizational Aspects of Medicine, ELOAM17 for Canada Health Act

**Definitions**

- **population health**
  - health of the population as measured by health status indicators (e.g. life expectancy, low birth weight rates)
  - influenced by: physical, biological, social, environmental, and economic factors; personal health behaviours; health care services
  - refers to the prevailing or desired level of health in the population of a specific country/region/subset of population
  - considered to be more complex than the aggregate health status of individuals within a population

- **public health**
  - systematic organized efforts to protect, promote, and restore the health of the public
  - refers to the practices, procedures, institutions, and disciplines required to achieve the desired state of population health

- **public health and preventive medicine** (formerly called community medicine)
  - the postgraduate study of health and disease in the population or a specified community
  - five-year Royal College specialty training
  - goal: to identify and address health problems and evaluate the extent to which health services and others address these issues (http://rcpesc.medical.org/information/index.php?specialty=110&submit=Select)

### Public Health Services in Canada

**Mission:** to promote and protect the health of Canadians, and reduce health inequities through leadership, partnership, innovation, and action in public health

- local public health units and services within regional health authorities (in most provinces except Ontario, where local public health units are either autonomous or within local government) provide programs and activities for health protection, promotion, and disease prevention at local and regional levels
- catchment-area populations range from hundreds to thousands of people, covering areas of 15 to 1.5 million km²

### Legislation and Public Health in Canada

Source: The AFMC Primer on Population Health is the core text for the MCC and is available as an online resource on the AFMC website.

For the LMCC exam, it is recommended that you also read all of Chapter 15 in Shah CP. Public health and preventive medicine in Canada, 5th ed. Toronto: Elsevier, 2003

Topics covered include:
- Primary, secondary, tertiary and quaternary health care
- Physician remuneration, organization of primary care, new model of primary health care
- Services of other health care professionals: nurses, dentists, chiropractors, podiatrists, optometrists, midwives, pharmacists, and alternative health care providers
- Hospitals and acute care facilities
- Local public health units: departments: communicable disease control, women’s health and maternal and child health, health promotion, dental health, environmental health, population health assessment and health surveillance
- Home care
- Palliative care
- Services for mental illnesses
- Services for cancer patients
- Services for persons with special needs
- Voluntary agencies
- Self-help groups
- Telehealth

Historical Perspective
Over the last century, Public Health has evolved through three main epidemiological phases:
- **Infectious diseases:** controlled in the more developed world but an issue in less developed countries (e.g. polio, malaria)
- **Chronic diseases:** chronic diseases and other noncommunicable conditions have increased morbidity and mortality (e.g. heart disease and cancer due to risk factors and/or exposures)
- **Re-emerging infectious diseases:** new or re-emergent infections emerge due to unfamiliar or new pathogens, inefficient or inappropriate antibiotic use, travel, and global warming (e.g. HIV, drug resistant TB and malaria)

Five Core Functions for All Public Health Units
- Population health assessment
- Health, injury, and disease surveillance
- Health promotion
- Disease and injury prevention
- Health protection
Concepts of Health

- **disease**: abnormal, medically-defined changes in the structure or function of the human body
- **illness**: an individual’s experience or subjective perception of a lack of physical or mental well-being and consequent inability to function normally in social roles
- **impairment**: any loss or abnormality of psychological, physiological, or anatomical structure or function
- **disability**: any restriction or lack of ability to perform an activity within the range considered normal for a human being
- **handicap**: the disadvantage for an individual arising due to impairment and disability
  - limits or prevents the fulfillment of an individual’s normal role as determined by society and depends on age, sex, social, and cultural factors
  - changes the individual's relationship with the physical and social environment
- **health equity**: when all people have the opportunity to attain their full health potential and no one is “disadvantaged from achieving this potential because of their social position or other socially determined circumstance.” Differs from health equality
- **health equality**: defined as where populations have equal or similar health status. Health inequities are those which are considered unjust and/or preventable

Determinants of Health

- 1974: the Honourable Marc Lalonde, federal Minister of Health, presented the health field concept entitled *A New Perspective on the Health of Canadians* which included four areas that interact to determine health: human biology, environment, lifestyle, and health care
- since then this concept has been expanded to include numerous determinants of health (see below)

<td>Smoking, Substance misuse, Excessive gambling, Poor nutrition, Sedentary lifestyle, High BMI, High risk sexual behaviours</td>
<td>Mental health awareness, Aboriginal-specific diabetes initiatives, Substance abuse treatment programs</td>
</tr>
</tbody>
</table>

---

**Definitions of Health**

- First multidimensional definition of health, as defined by the WHO in 1948: “A complete state of physical, mental and social well being and not merely the absence of illness.”
- WHO updated the definition (socio-ecological definition) of health in 1986: “The ability to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is therefore a resource for everyday life, not the objective of living. Health is a positive concept emphasizing social and personal resources, as well as physical capacities.”
- Other definitions of health have since been proposed that incorporate other dimensions of health (e.g. “Health is a social, economic, and political issue and above all a fundamental human right” – The People’s Charter for Health)

New Immigrants to Canada

- Mandatory medical exams on entry to Canada by a designated medical practitioner:
  - Complete medical examination for all persons of all ages
  - Chest x-ray and report for persons 11 yr of age and over
  - Urinalysis for persons 5 yr of age and over
  - Syphilis serology for persons 15 yr of age and over
  - HIV testing for applicants 15 yr of age and over, as well as for those children who have received blood or blood products, have a known HIV-positive mother, or have an identified risk. An ELISA HIV screening test should be done for HIV 1 and HIV 2
  - Serum creatinine if the applicant has hypertension (resting blood pressure greater than 140/90 mmHg), a history of treated hypertension, diabetes, autoimmune disorder, persistent proteinuria, or kidney disorder

Example of Primary Prevention: Gardasil Vaccine and its Efficacy in the Prevention of Cervical Cancer

Gardasil® is a quadrivalent HPV vaccine covering strains 6,11,16,18. The efficacy of Gardasil® was studied in 4 randomized, double-blind, placebo controlled trials on females between 16 and 26 yr of age and was found to prevent nearly 100% of precancerous cervical changes for up to 4 yr after vaccination.

Example of Primary Prevention: The Obesity Prevention Campaign by the Ontario Medical Association (OMA)

The OMA campaign has involved calls for early action on menu labeling from leaders in the restaurant field, lobbying the provincial government to enact legislation requiring calorie contents to be listed on menus at chain restaurants and school cafeterias, and an education campaign to inform the public about the impact of caloric intake on weight gain and obesity.

Disease Prevention Strategies

- measures aimed at preventing the occurrence, interrupting through early detection and treatment, or slowing the progression of disease/mitigating the sequelae

Primary Prevention

- implemented to prevent disease from occurring
- immunization programs exist in most countries to address major causes of pediatric morbidity and mortality that are preventable by vaccines, e.g. measles, diphtheria, pertussis, tetanus, polio, and tuberculosis (not routine in Canada or the U.S.)
• additional immunizations are offered in Canada depending on jurisdiction: mumps, rubella, rotavirus, hepatitis B, Haemophilus influenzae type B, varicella, HPV, conjugated pneumococcal and meningococcal vaccines (see Pediatrics, P3)

**Secondary Prevention (Screening)**
• presumptive identification (not diagnosis) of unrecognized disease or defect by the application of tests, examinations, or other procedures which can be applied rapidly
• types of screening
  ▪ mass screening: screening all members of a population for a disease (e.g. phenylketonuria (PKU) and hypothyroidism in all newborns)
  ▪ selective screening: screening of a specific subgroup of the population at risk for a disease (e.g. mammography in women >50 yr old)
  ▪ multiphasic screening: the use of many measurements and investigations to look for many disease entities (e.g. periodic health exam)

Table 3. Ideal Criteria for Screening Tests

<table>
<thead>
<tr>
<th>Disease</th>

<td>Safe, rapid, easy, relatively inexpensive</td>
<td>Cost effective</td>
</tr>
<tr>
<td>Must have an asymptomatic stage that can be detected by a test</td>
<td>Acceptable to providers and to population</td>
<td>Sustainable program</td>
</tr>
<tr>
<td>Early detection and intervention must result in improved outcomes</td>
<td></td>
<td>Clear policy guidelines</td>
</tr>
<tr>
<td>Incidence is not too high or too low</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Tertiary Prevention**
• treatment and rehabilitation of disease after it has been diagnosed so as to prevent progression and permanent disability (e.g. HbA1c, eye, and foot monitoring for diabetes)

**Health Promotion Strategies**

Table 4. Disease Prevention versus Health Promotion Approach

</tbody>
</table>

**Healthy Public Policy**
• characterized by an explicit concern for health and equity in all areas of policy and by an accountability for health impact
• main aim: to create a supportive environment to enable people to lead healthy lives, thereby making healthy choices easier for citizens
• government sectors must take into account health as an essential factor when formulating policy and should be accountable for the health consequences of their policy decisions
• methods:
  ▪ fiscal: imposing additional costs (e.g. taxes on tobacco and alcohol)
  ▪ legislative: implementing legal deterrents (e.g. smoking bans, legal alcohol drinking age)
  ▪ social: improving health beyond providing universally funded health care (e.g. providing affordable housing)

Source: International Conference on Health Promotion, Adelaide, South Australia (1998)

**Community Development**
• process of community members identifying issues and problems affecting their community and subsequently developing the skills and capacity to implement change

Source: Labonte’s Model of Community Development

**Disease Prevention Strategies**
• **Primary**: before disease occurs (e.g. immunizations, seatbelt use, smoking cessation programs for lung cancer prevention)
• **Secondary**: early detection of disease (e.g. mammography, routine Pap smears)
• **Tertiary**: treatment and rehabilitation of existing disease (e.g. ACE inhibitor for hypertension)

Within these three stages of prevention there can be both:
• **Passive prevention**: measures that operate without the person’s active involvement (e.g. airbags in cars)
• **Active prevention**: measures that a person must do on their own (e.g. wearing a seatbelt)

**Ottawa Charter for Health Promotion (1986)**
Governments and health care providers should be involved in a health promotion process that includes:
• Building healthy public policy
• Creating supportive environments
• Strengthening community action
• Developing personal skills
• Re-orienting health services

**Jakarta Declaration on Health Promotion into the 21st Century (WHO 1993)**
• Reiterated the commitment to health promotion
• First of the health promotion conferences to involve the private sector
• Formally cited poverty as the greatest threat to health
• Priorities for health promotion:
  ▪ Promote social responsibility for health
  ▪ Increase investments for health development
  ▪ Consolidate and expand partnerships for health
  ▪ Increase community capacity and empower the individual
  ▪ Secure an infrastructure for health promotion

**4 Ps Influencing Health Marketing**
Product: good health
Price: what a person must give up if he or she accepts the product “pursuing good health”
Place: the distribution channels used to reach the consumer (e.g. distributing pamphlets at the doctor’s office)
Promotion: the way in which the product is promoted to the consumer
Community-Based Prevention
- public health service (prevention or promotion) focused on an entire community as opposed to only high-risk groups/individuals
- “community-based approaches” are population-based multifactorial initiatives that make use of community organization and social marketing to elicit change at the community level (e.g. Saskatoon’s In Motion program – see sidebar)
- numerous preventable risk factors are addressed by multiple health promotion strategies

Health/Social Marketing
- application of the principles of commercial marketing to promote healthy changes
- involves target group analysis and segmentation of the market for specific messages and promotion strategies
- employed by both the health system (e.g. pamphlets providing health information about HIV) and by industry (e.g. in medication advertisements)

Behaviour Change
- health education serves to:
  - increase knowledge and skills
  - encourage positive behaviour changes and discourage unhealthy choices
- health education is an important component of eliciting behaviour change
- behaviour is a result of three factors
  1. predisposing factors: knowledge, attitude, beliefs, values, intentions
  2. enabling factors: skills, supports
  3. reinforcing factors: health care professionals and the social context of family and community

Health Belief Model (1975)
- behaviours undertaken by individuals in order to remain healthy are a function of a set of interacting beliefs
- beliefs include an individual’s perception of his or her susceptibility to a disease, the severity of the disease, and the benefits and costs of health-related actions
- beliefs are modified by socio-demographic and psychosocial variables
- individuals must believe that the action will have positive consequences
- individuals must be in a state of readiness
- behaviour can be stimulated by cues to action, which are specific events that can encourage preventive health decisions and actions (e.g. physician recommendation, public advertising)

Stages of Change Model
- provides a framework in which the Health Belief Model is applied to facilitating behaviour change (e.g. quitting smoking)

1. Precontemplation: the individual is not seriously considering change (for various reasons) and is not interested in any kind of intervention
2. Contemplation: the individual begins to seriously consider making the change within the foreseeable future (often defined as six months)
3. Preparation: the individual begins experimenting, making small changes; he or she resolves to make a serious attempt in the future (usually defined as 30 days)
4. Action: the individual is actively involved in making the change, using different techniques
5. Maintenance: the individual must learn to successfully cope with temptations to return to the previous behaviour pattern

Risk Reduction Strategies
- risk reduction: lower the risk to health without eliminating it (e.g. avoiding sun to lower risk of skin cancer)
- harm reduction: tolerance of some degree of risk behaviour, while aiming to minimize the adverse outcomes associated with these behaviours (e.g. needle exchange programs)

Innovation-Diffusion Theory
- theory that describes the process by which health promotion efforts spread in populations
- aims to identify the most effective methods of health promotion within a population
- Roger’s diffusion theory illustrates the following hierarchy within populations:
  - innovators
  - early adopters (community leaders)
  - early majority
  - late majority
  - laggards

Saskatoon’s In Motion
- is a community-based strategy to increase physical activity through collaborative community efforts. 98% of all Saskatoon schools have now committed to meeting In Motion goals, including at least 30 min of daily physical activity per child. Elementary schools also report that students are active on one additional day per week compared to pre-program activity levels. In Motion is viewed as a best practice strategy and is now being implemented in communities and provinces across Canada.

Example of Harm Reduction Strategy
Summary of Findings from the Evaluation of a Pilot Medically Supervised Safer Injecting Facility
CMAJ 2006;175:1399-1404
Background: This study discusses the outcomes among a population of illicit injection drug users (IDUs) after initiating a supervised safe injecting facility in Vancouver, September 2003. Legal exemption by the Canadian government was granted such that an evaluation of its results be conducted over a 3 yr period.
Study Population: IDUs of the Vancouver area were allowed to inject previously obtained illicit drugs under the supervision of nurses and physicians. IDUs were offered addiction counseling and supports for appropriate community resources. A random sample of 670 IDUs was recruited and monitored from Dec 2003-July 2004.
Results: Characteristics of IDUs who used the safe injecting facility included age <30 yr; history of public drug use, homelessness, daily heroin and/or cocaine injection, and recent history of overdose. Mean measures of public order problems were taken 6 wk before and 12 wk after initiation of the safer injecting facility. It was found that the mean number of IDUs injecting daily in public, along with the mean number of publically discarded syringes were reduced by approximately half.
Conclusions: Overall, it has been found that the safer injecting facility in Vancouver has been successful in attracting IDUs at increased risk of HIV, overdose, and public injection of substances. This has resulted in lower incidences of public drug use, publicly discarded syringes and sharing of needles. Other studies associated with this one have demonstrated that there has been no increase in the drug dealing, drug related crimes, or rates of new IDUs in the area surrounding the safer injecting facility.

Characteristics of Innovations that Influence Positive Adaptability of the Change
- Simple
- Workable
- Reversible
- Flexible
- Advantageous
- Cost effective
- Low risk
- Compatible with value systems

Figure 2. Stages of change model

To ronto Notes 2014
Measurements of Health and Disease in a Population

Life Expectancy
• the expected number of years that an individual will live based on standardized death rates for the population
• usually qualified by country, gender, and age

Crude Death Rate
• mortality rate from all causes of death per 1000 in the population

Age Standardized Rate
• adjustment of the crude rate of a health-related event using a “standard” population
• standard population is one with a known number of persons in each age and sex group (e.g. the 1991 census data for Canada using 5-yr age intervals for males and females)
• standardization prevents bias which could be made by comparing crude rates from two dissimilar populations (e.g. crude death rates over a number of decades are not comparable as the population age distribution has changed with time)

Standardized Mortality Rate
• the ratio of the observed (actual) number of deaths to the expected number of deaths for a group (e.g. age, race, gender, etc.)
• useful for comparing populations that are significantly different in some aspect (e.g. the causes of death in more and less developed countries)

Infant Mortality Rate (IMR)
• number of deaths among children under 1 yr of age reported during a given time period divided by the number of live births reported during the same time period and expressed per 1000 live births per year

Maternal Mortality Rate (MMR)
• number of deaths of women during pregnancy and due to puerperal causes per 100,000 live births per year

Proportional Mortality Ratio (PMR)
• proportion of all deaths in a specified population over a given period of time attributable to a specific cause
  ▪ each cause is expressed as a percentage of all deaths, with the sum of all causes adding to 100%

Potential Years of Life Lost (PYLL)
• calculated for a population using the difference between the actual age at death and a standard/expected age at death
• increased weighting of mortality at a younger age

Disability Adjusted Life Year (DALY)
• quantitative indicator of the burden of diseases that reflects the total amount of disability-free life years lost
• includes loss from premature mortality and loss due to a degree of disability over a specific period of time; these disabilities can be physical or mental

Quality Adjusted Life Year (QALY)
• a value from 0 to 1 assigned to a yr of life based on perceived quality of life; a yr in “perfect” health is considered equal to 1 QALY, the value of a yr in ill health would be lowered based on the burden of disease
• it is possible to have “states worse than death” for example QALY <0 for extremely serious conditions

Epidemiology

Population
• a collection of individuals who share a common trait (most commonly applied to a geographic area but it could be another factor such as ethnic group)
**Sample**
- A selection of individuals from a population or set of observations
- Types:
  - Random: all are equally likely to be selected
  - Systematic: an algorithm is used to select a subset
  - Stratified: separate representations of more than one subgroup
  - Cluster: grouped in space/time to reduce costs
  - Convenience: non-random inclusion, usually volunteers

**Sample Size**
- Sample size contributes to the statistical precision of the observed estimate
- Increasing the sample size decreases the probability of type I and type II errors (see PH14)

**Bias**
- Non-random error leading to a deviation of inferences or results from the truth
- Any trend in the collection, analysis, interpretation, publication, or review of data that can lead to conclusions that are systematically different from the truth
  - **Lead-time**: Time between early diagnosis with screening and when diagnosis would have been made without screening
  - **Lead-time bias**: Over-estimation of survival when the estimate is made from the time of screening, instead of the later time when the disease would have been diagnosed without screening (see Figure 3)
  - **Incidence-prevalence bias**: When prevalent cases include long-term survivors who have a better prognosis than some incident cases
  - **Length-time bias**: Overestimation of the survival time due to the sampling of prevalent as opposed to incident cases
    - Selection of prevalent cases will favor the over-inclusion of longer-living cases rather than newly-diagnosed incident cases, some of whom may have short survival times
  - **Sampling bias**: Occurs with the selection of a sample that does not truly represent the population
    - Sampling procedures should be chosen to prevent or minimize bias
  - **Recall bias**: When individuals with a disease are more prone to recalling or believing they were exposed to a possible causal factor than those who are free of disease

**Figure 3. Lead time bias**

**Confounder**
- A variable that is related to both the exposure and outcome but is not measured or is not distributed equally between groups
- Distorts the apparent effect of an exposure or risk because it may not be possible to separate/ control for the contribution of a single causal factor to an effect (e.g., late maternal age could be a confounder in an investigation of birth order >4 and risk of developing Trisomy 21)

**Prevalence**
- Total number of cases in a population over a defined period of time (see sidebar)
- Two forms of prevalence
  - **Point prevalence**: Attemps to measure the frequency of all disease at one specific point in time, therefore knowledge of the time of onset of disease is not required
  - **Period prevalence**: Measure constructed from prevalence at a point in time, plus new cases and recurrences over a defined period of time
- Depends on **incidence rate** (see sidebar) and disease duration from onset to termination (cure or death)
- Favours the inclusion of chronic over acute cases and may be used to present a biased picture of the disease
- Prevalence studies are cross-sectional and cannot be used for causal inferences
- Prevalence figures are useful for determining the extent of a disease and can aid in the rational planning of facilities and services

**Sensitivity**
- Proportion of people with disease who are correctly identified by a positive test

**Specificity** (refer to sidebar)
- Proportion of people without disease who are correctly identified by having a negative test

---

**Incidence and Prevalence**

- **Incidence**: Number of new cases of disease in a time interval (measures the rate of new infections)
  - \[ \text{Incidence} = \frac{\text{number of new cases}}{\text{total population at risk} \times \text{per unit population}} \]
  - (e.g. 100,000)

- **Prevalence**: Number of existing cases of disease at a point in time (measures the frequency of disease at a point in time)
  - \[ \text{Prevalence} = \frac{\text{number of existing cases}}{\text{total population} \times \text{per unit population}} \]
  - (e.g. 100,000)

**SPIN**: Use a **Specific** test to rule **IN** a hypothesis. Note that specific tests have very few false positives. If you get a positive test, it is likely a true positive.

**SNOUT**: Use a **Sensitivity** test to rule **OUT** a hypothesis. Note that sensitive tests have very few false negatives. If you get a negative test, it is likely a true negative.
Figure 4. Understanding sensitivity and specificity

Figure 4a. Hypothetical population

Figure 4b. Results of diagnostic test on hypothetical population

Figure 4c. Sensitivity of test (e.g. 24/30 = 80% sensitive)

Figure 4d. Specificity of test (e.g. 56/70 = 80% specific)

Source: Loong TW. Understanding sensitivity and specificity with the right side of the brain. BMJ 2003;327:716-719

TP = True positive   TN = True negative   FP = False positive   FN = False negative

Likelihood Ratio (LR)
• LR+ indicates how much the probability of disease increases if the test is positive
• LR- indicates how much the probability of disease decreases if the test is negative

\[
LR+ = \frac{\text{Sensitivity}}{1 - \text{Specificity}} = \frac{TP/(TP+FN)}{FP/(TN+FP)}
\]

\[
LR- = \frac{1 - \text{Sensitivity}}{\text{Specificity}} = \frac{FN/(TP+FN)}{TN/(TN+FP)}
\]

Positive Predictive Value (PPV)
• Proportion of people with a positive test who have the disease

\[
PPV = \frac{TP}{TP + FP}
\]

Negative Predictive Value (NPV)
• Proportion of people with a negative test who are free of disease

\[
NPV = \frac{TN}{TN + FN}
\]

Pre-test Probability
• An estimate of the likelihood a particular patient has a given disease based on known factors such as clinical assessment prevalence of disease in the population. Together with a post-test probability this can be used to interpret a diagnostic test or a series of tests

\[
\text{Pre-test Odds} = \frac{\text{Prevalence}}{1 - \text{Prevalence}}
\]

Post-test Probability
• A revision of the probability of disease after a patient has been examined or a diagnostic test has been conducted
• Calculation process can be more explicit using results from epidemiologic studies, knowledge of the accuracy of tests and Bayes’ theorem
• The post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies
• After each iteration the resultant post-test probability becomes the pre-test probability when considering new investigations

\[
\text{Post-test Odds} = \text{Pre-Test Odds} \times LR
\]

\[
\text{Post-test Probability} = \frac{\text{Post-test odds}}{\text{Post-test odds} + 1}
\]

Intention-To-Treat (ITT)
• A strategy for analyzing data in which all participants are included in the group to which they were assigned, whether or not they completed the requirements of that group
• This is to limit the bias introduced by issues of compliance and to simulate real world situations in which not all patients/providers adhere to the study allocation protocol

Relative Risk (RR)
• Ratio of the incidence of a health outcome among the exposed population to the incidence of the health outcome in the non-exposed population

\[
\text{Relative Risk (RR)} = \frac{\text{PPV}}{1 - \text{NPV}} = \frac{\frac{TP}{TP+FP}}{\frac{FN}{TN+FP}}
\]

Attributable Risk (AR)
• Rate of a health outcome attributable to a hypothetical risk factor for that outcome
• [Incidence in exposed population] - [Incidence in non-exposed]
• Attributable risk assumes causation

\[
\text{Attributable Risk} = \frac{\text{PPV} \times (1 - \text{NPV})}{\text{PPV} - (\text{PPV} \times (1 - \text{NPV}))}
\]

Advanced Neoplasia

<table>
<thead>
<tr>
<th>Test Result</th>
<th>Positive</th>

</table>

Sensitivity = 68/284 = 23.9%
Specificity = 2234/2381 = 93.8%

\[
\text{LR+} = \frac{0.239}{1 - 0.938} = 3.85
\]

\[
\text{LR-} = \frac{1 - 0.239}{0.938} = 0.81
\]

\[
\text{PPV} = \frac{68}{(68 + 147)} = 31.6%
\]

\[
\text{NPV} = \frac{2234}{(2234 + 216)} = 91.2%
\]

Figure 5. Clinical epidemiology definitions and practical example using FOBT testing in advanced colon cancer
Pre-test Probability
• an estimate of the likelihood a particular patient has a given disease based on known factors

Post-test Probability
• a revision of the probability of disease after a patient has been interviewed and examined
• calculation process can be more explicit using results from epidemiologic studies, knowledge of the accuracy of tests, and Bayes’ theorem
• the post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies
  ▪ after each iteration the resultant post-test probability becomes the pre-test probability when considering new investigations

Effectiveness of Interventions

DEFINITIONS

Relative Risk Reduction (RRR)
• proportional reduction in rates of adverse outcomes between experimental and control participants in a trial

Absolute Risk Reduction (ARR)
• absolute arithmetic difference in rates of adverse outcomes between experimental and control participants in a trial
• it is hypothesized that events will occur more often in control group than in experimental group where the intervention is protective (e.g. a vaccine)

Absolute Risk Increase (ARI)
• absolute arithmetic difference in rates of adverse outcomes between control and experimental participants in a trial
• it is hypothesized that events will occur more often in experimental group than in control group when the intervention is harmful (e.g. alcohol excess)

Number Needed to Treat (NNT)
• number of patients who need to be treated to achieve one additional favourable outcome
• only one of many factors that should be taken into account in clinical or health system decision making (e.g. must take into account cost, ease, feasibility, etc. of intervention)
  ▪ a condition with death as a potential outcome can have a higher NNT (and be acceptable), as compared to an intervention to prevent an outcome with low morbidity, in which a low NNT would be necessary

Number Needed to Harm (NNH)
• number of patients who, if they received the experimental treatment, would lead to one additional patient being harmed, compared with patients who received the control treatment

Adherence (formerly compliance)
• degree to which a patient follows a treatment plan
Effectiveness, Efficacy, Efficiency

- three measurements indicating the relative value (beneficial effects vs. harmful effects) of an intervention
  - **efficacy**: the extent to which a specific intervention produces a beneficial result under ideal conditions
  - ideally, based on the results of a randomized control trial (the theoretical impact)
  - **effectiveness**: measures the benefit of an intervention under usual conditions of clinical care
    - considers both the efficacy of an intervention and its actual impact on the real world, taking into account access to the intervention, whether it is offered to those who can benefit from it, its proper administration, acceptance of intervention, and degree of adherence to intervention
  - **efficiency**: a measure of economy of an intervention with known effectiveness
    - considers the optimal use of resources (e.g. money, time, personnel, equipment, etc.)

### Types of Study Design

#### Qualitative vs. Quantitative

<table>
<thead>
<tr>
<th>Qualitative</th>
<th>Quantitative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generates hypothesis (Why? What does it mean?)</td>
<td>Tests hypothesis (What? How much/many?)</td>
</tr>
<tr>
<td>Inductive (specific to general): “bottom up”</td>
<td>Deductive (general to specific): “top down”</td>
</tr>
<tr>
<td>Observation → pattern → tentative hypothesis → theory</td>
<td>Theory → hypothesis → observation → confirmation</td>
</tr>
<tr>
<td>Sampling approach to obtain representative coverage of ideas or concepts</td>
<td>Sampling approach to obtain representative coverage of people in the population</td>
</tr>
<tr>
<td>Narrative: rich, contextual, and detailed information from a small number of participants</td>
<td>Numeric: frequency, severity, and associations from a large number of participants</td>
</tr>
</tbody>
</table>

#### Quantitative Research Methods

![Figure 7. Quantitative study designs](http://phprimer.afmc.ca)
# Observational Study Designs

- observational studies involve neither the manipulation of the exposure of interest nor randomization of the study subjects
- there are two main subtypes of observational studies: descriptive and analytic studies

## Descriptive Studies
- describe the events and rates of disease with respect to person, place and time and to estimate disease frequency and time trends
- first sets of studies and are used to generate an etiologic hypothesis, not test a hypothesis

## Analytic Studies
- observational studies used to test a specific hypothesis
- includes ecological studies, cohort studies, case-control studies, and cross-sectional studies

## Table 6. Observational Study Designs

<table>
<thead>
<tr>
<th>Type of Study</th>
<th>Ecological</th>
<th>Cross-Sectional</th>
<th>Case-Control (Figure 8)</th>
<th>Cohort (Figure 9)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Definition</strong></td>
<td>Units of analysis are populations or groups of people, rather than individuals</td>
<td>Assessment of individuals with respect to presence and absence of exposures and diseases at the same point in time</td>
<td>Samples a group of people who already have a particular outcome (cases) and compares them to a similar sample group without that outcome (controls)</td>
<td>Subjects are sampled and, as a group, classified on the basis of presence or absence of exposure to a particular risk factor</td>
</tr>
<tr>
<td><strong>Subjects</strong></td>
<td>Population (e.g., geographic areas)</td>
<td>Population (sample)</td>
<td>Two study sample populations are compared: cases and controls</td>
<td>One or more cohorts Cohort: group of people with common characteristics (e.g., year of birth) Divided into measured exposed vs. non-exposed groups</td>
</tr>
<tr>
<td><strong>Methods</strong></td>
<td>Accurate descriptions of the average exposure or risk of disease for a population Collect information from each person at one particular time Tabulate the numbers in groups (e.g., by presence or absence of disease/factor of interest) Make 2 x 2 table and compare groups Estimate prevalence</td>
<td>Collect information about exposures Select all the cases of a specific disease during a specific time frame Representative of spectrum of clinical disease Select control(s) Represent the general population To minimize risk of bias, may select more than one control group and/or match controls to cases (e.g., age, gender) Association can be concluded between the risk factor and the disease (odds ratio) Estimate incidence</td>
<td>Ask cases and controls about exposures Select all the cases of a specific disease during a specific time frame Representative of spectrum of clinical disease Select control(s) Represent the general population To minimize risk of bias, may select more than one control group and/or match controls to cases (e.g., age, gender) Association can be concluded between the risk factor and the disease (odds ratio) Estimate incidence</td>
<td>Subjects are followed for a specific period of time to determine development of disease in each exposure group Prospective: measuring from the exposure to the future outcomes – looking forward Retrospective: measuring from outcomes to possible risk factors or protective factors – looking back Collect information on factors from all persons at the beginning of the study Tabulate the number of persons who develop the disease or other measured outcomes of morbidity Provides estimates of incidence, relative risk, attributable risk</td>
</tr>
<tr>
<td><strong>Advantages</strong></td>
<td>Quick, easy to do Uses readily available data Generates hypothesis Determines association between variables Quick and uses limited resources Surveys with validated questions allows comparison between studies Used when disease in population is rare (less than 10% of population) due to increased efficiency Less costly and time consuming Shows an association between a factor and an outcome/several outcomes Stronger evidence for causation</td>
<td>Does not allow for assessment of temporal relationship or causation between variables Recall bias (see PH8) Recall bias (see PH8) Confounding Selection bias for controls Only one outcome can be measured</td>
<td>By itself, cannot establish causation Confounding factors are common as the cohort self-selects the exposure, or unknown/unknown factors are associated with the measured exposure Cost and duration of time needed to follow cohort</td>
<td></td>
</tr>
<tr>
<td><strong>Disadvantages</strong></td>
<td>Poor generalizability to individual level (not direct assessment of causal relationship) Ecological fallacy: an incorrect inference about individuals in the population</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

An example of a descriptive study is one that explores the rates of AIDS by age, sex, geographic distribution, and over time.

An example of an ecological study would be one looking at the association between smoking rates and lung cancer rates in different countries.

An example of an ecological fallacy would be concluding that red wine drinking leads to lower risk of death from CVS disease after an ecological study shows that France has a higher rate of red wine consumption and a lower rate of death from CVS causes.

An example of an ecological study is the Framingham Heart Study, which assesses the long-term cardiovascular risks of diet, exercise, medications such as Aspirin®, etc.

An example of a famous cohort study is the Framingham Heart Study, which assesses the long-term cardiovascular risks of diet, exercise, medications such as Aspirin®, etc.

An example of a famous case control study is by Sir Richard Doll who demonstrated the link between tobacco smoking exposure and lung cancer cases.

An example of an ecological study is that which examines the distribution of BMI by age in Ontario at a particular point in time.
Experimental Study Designs

- not discussed here are non-randomized control trials (e.g. allocation by clinic or other non-random basis – performed when randomization is not possible) and clinical trials (test treatments or laboratory tests in human subjects)

1. RANDOMIZED CONTROLLED TRIAL (RCT)

**Definition**
- subjects are assigned by random allocation to two or more groups, one of which is the control group, the other group(s) receive(s) an experimental intervention

**Subjects**
- individuals are separated into groups by a random process to ensure as much as possible equal distribution of known and unknown factors except for the experimental exposure (e.g. the treatment)

**Methods**
- random allocation of individuals into two or more treatment groups through a centralized concealed process
- method of assessment to reduce bias
  - **single-blind**: subject does not know group assignment (intervention or placebo)
  - **double-blind**: subject and observer both unaware of group assignment
  - **triple-blind**: subject, observer, and analyst unaware of group assignment (rarely done)
- one group receives placebo or standard therapy
- one or more groups receive(s) the intervention(s) under study
- the outcome is measured and the groups are compared
- all other conditions are kept the same between groups

**Advantages**
- “gold standard” of studies, upon which the practice of EBM is founded
- provides the strongest evidence for effectiveness of intervention
- with sufficient sample size and appropriate randomization, threats to validity are minimized
- allows prospective assessment of the effects of intervention while minimizing bias

**Disadvantages**
- some exposures are not amenable to randomization (e.g. cannot randomize subjects to poverty/wealth or to harmful exposures such as smoking) due to ethical or feasibility concerns
- difficult to randomly allocate groups (e.g. communities, neighbourhoods)
- difficult to study rare events, since RCTs would require extremely large sample sizes
- costly

Other Study Designs

1. META-ANALYSIS

**Definition**
- combines the results of independent (studies identified through a systematic review) that address a common research hypothesis into one large study

**Subjects**
- combination of all the subjects used in original studies

**Methods**
- selection of relevant studies from the published literature which meet quality criteria
- statistical models used to combine the results of each independent study
- provides a summary statistic of overall results as well as graphic representation of included studies

**Advantages**
- attempts to overcome the problem of reduced power due to small sample sizes of individual studies
- ability to control for inter-study variation

**Disadvantages**
- sources of bias may not be controlled for
- reliance on published studies may increase the potential conclusion of an effect as it can be difficult to publish studies that show no significant results (publication bias)
- the decision to include/reject a particular study is subjective
Methods of Analysis

Distributions

- distribution describes the probability of events
- normal (Gaussian) or non-normal (skewed, bimodal, etc.)
- characteristics of the normal distribution
  - mean = median = mode
  - 67% of observations fall within one standard deviation of the mean
  - 95% of observations fall within two standard deviations of the mean
- measures of central tendency
  - mean: sum of all observations divided by total number of variables
  - median: value at the 50th percentile, this is a better reflection of the central tendency for a skewed distribution
  - mode: most frequently observed value in a series
- measures of dispersion
  - range: the largest value minus the smallest value
  - variance: a measure of the spread of data
  - standard deviation: the average distance of data points from the mean (the positive square root of variance)
- given the mean and standard deviation of a normal or binomial distribution curve, a description of the entire distribution of data is obtained

Data Analysis

Statistical Hypotheses

- null (H₀)
  - no relationship exists between the two stated variables (i.e. no association between the hypothesized exposure and the outcome)
- alternative (H₁)
  - a relationship does exist between the two stated variables

Type I Error (α Error)

- the null hypothesis is falsely rejected (e.g. concluding an intervention X is effective when it is not, or declaring an observed difference to be real rather than by chance)
- the probability of this error is denoted by the p-value
- studies tend to be designed to minimize this type of error, since a type I error can have larger clinical significance than a type II error

Type II Error (β Error)

- the null hypothesis is falsely accepted (e.g. stating intervention X is not effective when it is, or declaring an observed difference/effect to have occurred by chance when it is present)
- higher level of error is acceptable for most studies
- can also be used to calculate statistical power

Power

- probability of correctly rejecting a null hypothesis when it is in fact false (i.e. the probability of finding a specified difference to be statistically significant at a given p-value)
- power increases with an increase in sample size
- power = 1 – β, and is therefore equal to the probability of a true positive result

Statistical Significance

- the probability that the statistical association found between the variables is due to random chance alone (i.e. that there is no association)
- the preset probability is set sufficiently low that one would act on the result; frequently p=0.05
- when statistical tests result in a probability less than the preset limit, the results are said to be statistically significant (i.e. p<0.05)

Clinical Significance

- measure of clinical usefulness (e.g. 1 mmHg BP reduction may be statistically significant, but may not be clinically significant)
- depends on factors such as cost, availability, patient compliance, and side effects in addition to statistical significance

Trend

- an observed directional relationship that does not meet criteria for statistical significance and thus should be interpreted with caution

Example Calculation

Data set: 17, 14, 17, 10, 7
Mean = (17 + 14 + 17 + 10 + 7) ÷ 5 = 13
Median (write the list in order, median is the number in the middle)
= 7, 10, 14, 17, 17 = 14
Mode (number repeated more often)
= 17
Range = 17 - 7 = 10
Variance = [(17 – 13)² + (14 – 13) ² + (17 – 13) ² + (10 – 13) ² + (7 – 13) ²] ÷ 5 = 19.5
Standard Deviation = √variance = √19.5 = 4.42
Confidence Interval (CI)
- provides a range of values within which the true population result (e.g. the mean) lies
- frequently reported as 95% CI (e.g. one can be 95% certain that the true value is within this data range)
- bounded by the upper and lower confidence limits

Data
- information collected from a sample of a population
- there are 2 overall classes of data listed with examples:
  - discrete
    - categorical (e.g. gender, marital status)
    - ordinal (e.g. low, medium, high)
  - continuous (e.g. serum cholesterol, hemoglobin, age)

Accuracy
- how closely a measurement approaches the true value

Reliability
- how consistent a measurement is when performed by different observers under the same conditions or by the same observer under different conditions

Validity
- extent to which a measurement approaches what it is designed to measure
- determined by the accuracy and reliability of a test

Internal Validity
- degree to which the findings of the sample truly represent the findings in the study population
- dependent on the precision and accuracy

External Validity
- degree to which the results of the study can be generalized to other situations or populations

Common Statistical Tests

A wider confidence interval implies more variance than a tighter confidence interval.
Causation

Criteria for Causation (Sir Bradford Hill)
1. strength of association: the frequency with which the factor is found in the disease and the frequency with which it occurs in the absence of disease
2. consistency: is it the same outcome with different populations or study design?
3. specificity: is the association particular to your intervention and measured outcome?
4. temporal relationship: did the exposure occur before the onset of the disease?
5. biological gradient: finding a quantitative relationship between the factor and the frequency (e.g. dose response relationship)
6. biological plausibility: does the association/causation make biological sense?
7. coherence: can the relationship be explained/accounted for based on what we know about the laws of science, logic, etc.?
8. experimental evidence: experiment that investigates what happens when the suspected offending agent is removed (e.g. is there improvement?)
9. analogy: do other established associations provide a model for this type of the relationship?

Note: not all criteria must be fulfilled to establish scientific causation, and the modern practice of EBM emphasizes ‘experimental evidence’ as superior to other criteria for experimental causation review. However many causation questions in health cannot be answered with experimental methods.

Assessing Evidence

• critical appraisal is the process of systematically examining research evidence to assess validity, results, and relevance before using it to inform a decision

Figure 12. Pyramid of pre-appraised evidence

VALIDITY
- The degree to which the outcome observed in the study can be attributed to the intervention
- Were all patients randomized?
- Were all patients analyzed in the groups to which they were randomized?
- Were all patients treated equally except for the intervention?
- Were all patients analyzed in the study? Were they followed up?
- Were all patients randomized? Were the groups similar (i.e. demographics, prognostic factors) at the start of the trial?
- Were outcome assessors aware of group allocation? Were ethical issues continuously upheld?

Analysis
- Per-Protocol Analysis (PP)
  Strategy of analysis in which only patients who complete the entire study are counted towards the results.
- Intention-to-Treat Analysis (ITT)
  When groups are analyzed exactly as they existed upon randomization (i.e. using data from all patients, including those who did not complete the study).
Health Services Research

Continuous Quality Improvement (CQI)

Quality Improvement
- method of evaluating and improving processes; focusing more on systems and systematic biases, which are thought to be the cause of variation in quality, as opposed to individuals
- taking measures to increase efficiency of action with the purpose of achieving optimal quality

Quality Assurance
- management system to assure the quality of health care provided by workers and received by patients
- constantly aims to improve standards and the frequency of attaining those standards
- five-stage process of quality assurance
  - establishment of functional goals
  - implementation of procedures to achieve those goals
  - regular assessment of performance relative to the goals
  - proposal of solutions to close the gap between performance and goals
  - documentation and reporting of this assessment activity

Quality Control
- method of maintaining standards by reviewing the quality of all factors involved in the process

Continuous Quality Improvement
- management approach to improve and maintain quality via continuous assessment of potential defects, followed by action to improve process, avoid decrease in quality or correcting process in early stages
- continuous feed-forward process

Quality Management
- encompasses quality assurance, quality control and quality improvement to achieve consistent quality

Total Quality Management
- management philosophy for improving quality while controlling costs
- focusing on the system rather than the individual, to ensure decisions are made to support quality and remove barriers to quality inherent in bureaucratic, hierarchical systems

Audit
- process of systematic examination of a quality system carried out by internal or external quality auditors
- to determine whether quality processes and results comply with goals, and whether processes have been implemented effectively

Systems Analyses Tools
1. 5 Whys: brainstorming to simplify the process of change; continue asking 'why' until the root of the problem is discovered
2. Ishikawa Diagrams (aka Fishbone Diagrams): identify generic categories of problems that have an overall contribution on the effect (see Figure 13)
3. **Defect check sheets:** consider all defects and tally up the number of times the defect occurs

4. **Pareto Chart:** x vs. y chart; x-axis = defect categories, y-axis = frequency; plot cumulative frequency on the right y-axis
   - Purpose is to highlight most important among large set of factors contributing to defects/poor quality

**Precede-Proceed Model**
- Tool for designing, implementing, and evaluating health interventions/programs

**Table 8. Precede-Proceed Model**

<table>
<thead>
<tr>
<th>PRECEDE Phase</th>
<th>PROCEED Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 1 – Identify the ultimate desired result</td>

<td></td>
</tr>
<tr>
<td>Phase 4 – Identify the administrative and policy factors that</td>
<td></td>
</tr>
<tr>
<td>influence what can be implemented</td>
<td></td>
</tr>
</tbody>
</table>

**Cost Analysis**

**Cost Benefit Analysis**
- A process of, either explicitly or implicitly, weighing the total expected costs against the total expected benefits of one or more actions in order to choose the best or most profitable option
- All costs are adjusted for the time value of money, so that costs that may change over time are expressed on a common basis in terms of their present value

**Cost Effectiveness Analysis (CEA)**
- A comparison of the relative expenditure (costs) and outcomes (effects) of two or more courses of action
- Cost effectiveness analysis is often used where a full cost benefit analysis is inappropriate
- A CEA is commonly expressed in terms of a ratio: the denominator is a gain in health from a measure (e.g. years of life, premature births averted, sight-years gained) and the numerator is the cost of the health gain
- The most commonly used outcome measure is quality-adjusted life years (QALY)

**Outbreak of Infectious Diseases**

**Definitions**

**Outbreak**
- Occurrence of new cases clearly in excess of the baseline frequency of the disease in a defined community or population over a given period of time
- Synonymous with epidemic, although generally considered to be an epidemic that is localized, has an acute onset, or is relatively short in duration
Epidemic
• any disease, infectious or chronic, occurring at a greater frequency than usually expected in a defined community or institutional population over a given time period (i.e. excessive rate of disease)

Endemic
• constant presence of disease or infectious agent in a given geographic area or population subgroup (i.e. usual rate of disease)

Pandemic
• epidemic over a wide area, crossing international boundaries, and affecting a large number of people

Attack Rate
• cumulative incidence of infection within a defined group observed during a specific period of time in an epidemic
• calculated by dividing the total number of people who develop clinical disease by the population at risk, usually expressed as a percentage

Secondary Attack Rate
• number of cases among contacts occurring within the incubation period following exposure to the primary case, in relation to the total exposed contacts
• infectiousness reflects the ease of disease transmission and is usually measured by the secondary attack rate

Pathogenicity Rate
• power of an organism to produce clinical disease in those that are affected

Virulence
• severity of the disease produced by the organism in a given host
• expressed as the ratio of the number of cases of severe and fatal infection to the total number of clinically affected

Case-Fatality Rate
• proportion of individuals contracting a disease who die as a result of that disease
• most frequently applied to a specific outbreak of acute disease in which all patients have been followed for an adequate period of time to include all attributable deaths
• must be clearly differentiated from the mortality rate

Mortality Rate/Crude Death Rate
• estimation of the portion of the population that dies during a specified period from all causes of death

All-Cause Mortality Rate by Age Group
• estimation of the portion of the population in a given age group that dies during a specified period from all causes of death for that age group

Morbidity Rate
• estimation of the portion of the population that suffers illness or ill health during a specified period

Steps to Control an Outbreak

1. Define the Problem
• is it an outbreak?

2. Appraise Existing Data and Institute a Surveillance System
• case definition: formulated from the most common symptoms or signs; definition includes the likely date of onset of illness of the first case (e.g. any person with onset of fever higher than 38.5°C and cough within past 28 d)
• active surveillance: identify those who may have been exposed to the infectious agent and who fit the case definition through active efforts, including:

3. Formulate Hypotheses and Implement Initial Control Measures
• track outbreak evolution to develop hypotheses about potential source and populations at risk
• case management depends on symptoms, suspected agent, population at risk, and location
• population management requires public health services in the community and infection control teams in hospitals to disseminate information about
  • risk reduction
  • personal preventative measures (e.g. post-exposure prophylaxis)
  • decreasing risk of propagation (e.g. quarantine)
4. Test the Hypothesis through Analysis of Surveillance Data or Special Studies

- analyze outbreak surveillance data
- generate epidemic curves
  - usually a frequency histogram, with the number of cases plotted on the vertical axis and dates or times of onset along the horizontal axis
  - curve can indicate whether the epidemic (outbreak) has a common source or whether it is propagated
  - point source epidemic: exposure is brief and essentially simultaneous (see Figure 15a)
  - extended source epidemic: exposure lasts for a period of days to weeks and may be continuous (no irregular peaks, see Figure 15b) or intermittent (irregularly spaced peaks)
  - propagated epidemic: begins with only a few exposed persons but is maintained by person-to-person transmission (e.g. measles/influenza); epidemic curve shows a series of peaks (see Figure 15c)
- use epidemic curves, cross-sectional studies, and/or case-control studies to evaluate hypotheses about cause of outbreak

5. Draw Conclusions and Re-Adjust Hypothesis and Control Measures

- establish cause of outbreak with further epidemiologic investigation and revise initial control measures accordingly

6. Plan for Long-Term Prevention and Control

- implement prevention measures to avoid similar future incidents
  - strengthen resistance of hosts (e.g. immunization)
  - interrupt modes of transmission in environment (e.g. improvements in food processing)
- communicate outbreak prevention and control strategies to the public

**Environmental Health**

**Definition**
- study of conditions in the natural and human-made environment that influence human health and well-being
- environmental exposures
  - four main reservoirs: air, food, water, and soil
  - three main routes: inhalation, ingestion, or absorption (skin)
  - usually divided into two main settings:
    - workplace (including schools): may see high level exposure in healthy individuals (see Occupational Health, PH23)
    - non-workplace: generally low level but chronic exposure; population at risk includes extremes of age, developing fetuses, and ill or immunocompromised individuals
- health impacts of the environment also include factors such as urban planning and how individuals interact with the built environment (e.g. safe pedestrian and bicycle paths are neighbourhood features that can facilitate more active lifestyles among residents)

**Environmental Health Jurisdiction**

Risk Assessment

Hazard Identification
- what is the hazard involved?
- assess potential hazards by taking an environmental health history

Risk Characterization
- is the identified agent likely to elicit the patient's current symptoms?
- review known health impacts of the hazard and identify specific properties that contribute to or diminish adverse effects (e.g. some agents only become dangerous at threshold levels)

Exposure Assessment
- is the patient's exposure to the environmental agent sufficient to have caused the current symptoms?
- quantify exposure through direct measurement or by reviewing frequency and nature of contact with hazard

Air

Physical Contaminants
- sound waves
  - ionizing radiation
  - radon is naturally produced by soil containing uranium or radium, can contaminate indoor air and is associated with a small proportion of lung cancers
- ultraviolet radiation is increasing due to ozone layer destruction and increases risk of skin cancer
  - non-ionizing radiation
  - visible light, infrared, microwave

Chemical Contaminants
- ground-level ozone
  - main component of smog with levels increasing in major cities
  - worsens asthma, irritates upper airway
- carbon monoxide (fossil fuel related, common byproduct of combustion)
  - aggravates cardiac disease at low levels
  - headache, nausea, dizziness at moderate levels
  - fatal at high levels
- sulphur dioxide (fossil fuel related), nitrogen oxides
  - contribute to acid rain
  - exacerbate breathing difficulties
- organic compounds (e.g. benzene, methylene chloride, tetrachloroethylene)
  - variety of health effects at high levels (e.g. benzene is a known carcinogen)
  - tend to be fat-soluble, easily absorbed through skin and difficult to excrete
- heavy metals (e.g. nickel, cadmium, chromium)
  - present in industrial emissions
- variety of health effects: upper airway disease, asthma, decreased lung function
- second hand tobacco smoke
  - respiratory problems, increase risk of lung cancer

Biological Contaminants
- particulates
  - associated with decreased lung function, asthma, upper airway irritation
- moulds thrive in moist areas; 10-15% of the population allergic
- bacteria survive as spores and aerosols, can be distributed through ventilation systems (e.g. Legionella)
- dust mites (year-round) and pollens (seasonal) can trigger upper and lower-airway symptoms

Climate Change
- anthropogenic greenhouse gas emissions (e.g. carbon dioxide, methane) leading to adverse changes in the global environment
  - increased extreme weather conditions (e.g. floods, hurricanes, heat waves)
  - increased distribution of disease vectors (e.g. mosquitoes and malaria)
  - increased malnutrition from crop failures
  - increased diarrheal diseases

BPA, the Toxin Concern of 2009
Bisphenol A (BPA) is a chemical compound found in some hard, clear, lightweight plastics and resins. According to the NIH, animal studies suggest that ingested BPA may imitate estrogen and other hormones. In October 2008, Canada became the first country in the world to ban the import and sale of polycarbonate baby bottles containing BPA, stating that although exposure levels are below levels that cause negative effects, current safety margins need to be higher. The US FDA does not consider normal exposure to BPA to be a hazard, however the NIH has some concern that fetuses, infants, and children exposed to BPA may be at increased risk for early-onset puberty, prostate, and breast cancer.

Effects of Ionizing Radiation
- α-particles are larger and damage the skin and bronchial lining (airway irritation).
- β-particles are smaller and cause deeper damage (alveoli).
Water

Biological Contaminants
- mostly due to human and animal waste
- Aboriginal Canadians, rural Canadians at higher risk
- bacteria: *Escherichia coli* (e.g. Walkerton, ON), *Salmonella*, *Pseudomonas*, *Shigella*
- protozoa: *Giardia*, *Cryptosporidium* (e.g. North Battleford, SK)

Chemical/Industrial Contaminants
- chlorination by-products (e.g. chloriform can cause cancer at high levels)
- volatile organic compounds, heavy metals, pesticides, and other industrial waste products can be present in groundwater
- fluoride at high levels (greater than that of municipal fluoridation) can cause skeletal fluorosis

Soil

- contamination sources: rupture of underground storage tanks, use of pesticides and herbicides, percolation of contaminated water runoffs, leaching of wastes from landfills, dust from smelting and coal burning power plants, direct discharge of industrial wastes, lead deposition, leakage of transformers
- most common chemicals: petroleum hydrocarbons, solvents, lead, pesticides, motor oil, other industrial waste products
- health effects:
  - infants and toddlers at highest risk of exposure due to hand-mouth behaviours
  - dependent on contaminant: leukemia, kidney damage, liver toxicity, neuromuscular blockade, developmental damage to the brain and nervous system, skin rash, eye irritation, headache, nausea, fatigue
- biological contamination: tetanus, *Pseudomonas*

<td>Dizziness, weakness, respiratory failure, GI symptoms: thirst, nausea, constipation</td>
</tr>
</tbody>
</table>

Prion (BSE)
- Beef and beef products
- Creutzfeldt-Jakob disease

other biological food contaminants include:
- viruses
- mould toxins (e.g. aflatoxin → liver cancer)
- parasites (e.g. *Toxoplasmosis*, tapeworm)
- paralytic and shellfish poisoning (rare)
- genetically modified organisms (GMO) – controversial with respect to health and environmental risk/benefits

Chemical Contaminants
- many persistent organic pollutants are fat-soluble and undergo bioamplification
- drugs (antibiotics, hormones)
- inadequately prepared herbal medications
- food additives and preservatives
  - nitrites highest in cured meats; can be converted to carcinogenic nitrosamines
  - sulphites commonly used as preservatives; associated with sulphite allergy (hives, nausea, shock)
- pesticide residues
  - older pesticides (e.g. DDT) have considerable human health effects
  - debate over risks of DDT vs. risks of malaria in malaria-endemic countries

Table 10. Comparison of Select Biological Contaminants of Food and Effects on Human Health

- *Honey and Botulism*
  - Although exceedingly rare, infant botulism has been documented as a form of food poisoning from *C. botulinum* found in honey. When an infant swallows spores of this bacterium, they grow and produce a toxin in the baby’s intestine. By the time an infant is 1, its gut has a healthy colony of “good” bacteria that prevents this from occurring.

- *To Fluoridate or Not*
  - At the recommended concentration of 0.8-1.0 mg/L, fluoride reduces cavities by 18-40%, and there is little risk of fluorosis unless other exposures (e.g. toothpaste, rinses, mouthwash, etc.) are swallowed. Opposition raises concerns that the intake is not easily controlled, and that children, and others may be more susceptible to health problems. However, public health experts strongly support fluoridation as an effective measure to prevent dental caries at the community level and reduce dental health inequities.

- *The Walkerton Tragedy*
  - In May 2000, the drinking water system in the town of Walkerton, ON, became contaminated with *Escherichia coli* 0157:H7 and *Campylobacter* jejuni. Over 2,300 individuals became ill; 27 people developed hemolytic uremic syndrome and 7 individuals died in the outbreak.

- *Organic Foods*
  - Foods designated as “organic” in Canada must conform to the Organic Products Regulations enforced by the Canadian Food Inspection Agency
    - Organic foods are not free of synthetic pesticide residues but typically contain smaller amounts compared to conventionally grown foods
    - Currently, there has not been strong evidence to suggest that eating organic foods is safer or more nutritious compared to eating conventionally grown food

- *To Toronto Notes 2014*
  - To Toronto Notes 2014
  - To Toronto Notes 2014

• polychlorinated biphenyls (PCBs)
  § effects (severe acne, numbness, muscle spasm, bronchitis) much more likely to be seen in occupationally exposed individuals than in the general population
• dioxins and furans
  § levels highest in fish and marine mammals, also present in breast milk
  § can cause immunosuppression, liver disease, respiratory disease

### Heavy Metal Toxicity

**Mechanism**
• after exposure, superabundant metals bind to proteins, alter their enzymatic activity, and lead to diffuse disease manifestations

**Predisposing Factors in At-Risk Groups**
• children: hand-to-mouth, incomplete blood brain barrier
• pregnant women and developing fetus: heavy metals cross placenta; mothers release heavy metal stores at times of calcium stress
• adults: occupation, hobbies, environment (home, country)

**Etiology**
• iatrogenic (e.g. gold treatment for rheumatoid arthritis, lithium treatment for bipolar affective disorder)
• inhalation (e.g. zinc oxide, lead gasoline fumes)
• ingestion (e.g. lead paint, mercury in fish, folk remedies)
• industry (e.g. methyl mercury industrial spill caused Minamata disease)

**Treatment**
• generalized workup: symptoms are usually wide-ranging and non-specific
• chelation therapy (e.g. dimercaprol)

### Occupational Health

• occupational health is the maintenance and promotion of health in the work environment
• occupational health services include physicians, nurses, engineers, ergonomists, safety officers, physicists, technicians and others
• services encompass health promotion and protection (primary prevention), disease prevention (secondary prevention), and treatment and rehabilitation (tertiary prevention)
• general bias towards reporting occupational injuries versus occupational disease, as occupational disease is harder to identify

### Workplace Health Promotion and Protection

• take action in the workplace so the worker is protected from injury or illness
  § identifying workplace hazards [e.g. through material safety data sheets (MSDS)]
  § assessing risk
  § reducing exposure
    § source: substituting a less toxic chemical
    § path: enclosing a source of noise in a sound-proof room
    § worker: personal protection equipment (e.g. reflective vests, helmets)
    § worker education: emergency protocols, material safety education
    § rotation of workers: decrease exposure for each worker but more workers exposed

### Workplace Disease Prevention

• monitor workers’ health to prevent the development of disease
  § periodic examinations to facilitate pre-symptomatic diagnosis (e.g. screening for lead exposure); substance misuse screening where performance impairment is suspected

### Workplace Treatment and Rehabilitation

• treat injury or illness with safe return to the workplace
• may require rehabilitation, retraining, change in job duties, and/or workers’ compensation
**Workplace Legislation**

- universal across Canada for corporate responsibility in the workplace; due diligence, application of Workplace Hazardous Materials Information System (WHMIS), existence of joint health and safety committees in the workplace with representatives from workers and management
- jurisdiction in Canada is provincial (90% of Canadian workers), except for 16 federally regulated industries (e.g. airports, banks, highway transport) under the Canada Labour Code
- Ontario’s Occupational Health and Safety Act
  - sets out rights of workers and duties of employers, procedures for dealing with workplace hazards, and law enforcement
  - workers have the right to
    - participate (e.g. have representatives on joint health and safety committees)
    - know (e.g. be trained and have information about workplace hazards)
    - refuse work (e.g. workers can decline tasks they feel are overly dangerous)
    - stop work (e.g. ‘certified’ workers can halt work if they feel it is dangerous to other workers)
  - employers must take precautions to protect the health and safety of employees and investigate concerns
  - enforced by Ministry of Labour via inspectors
- Health Protection and Promotion Act (HPPA) (Ontario)
  - Medical Officer of Health has right to investigate and manage health hazards where workplace exposures may impact non-workers (e.g. community members living close to the work site)

**Taking an Occupational Health History**

- current and previous job duties
- exposures
  - identification: screen for chemical, metal, dust, biologic, psychologic and physical hazards; review relevant workplace material safety data sheets (MSDS)
  - assessment: duration, concentration, route, exposure controls (e.g. ventilation, personal protective equipment)
- temporal relationship: changes in symptoms in relationship to work environment
- presence of similar symptoms in co-workers
- non-work exposures: home, neighbourhood, hobbies

**Occupational Hazards**

Appendix – Reportable Diseases

As an essential part of the health system, physicians in Canada are required by law to report certain diseases to public health for the following reasons:

1. to control the outbreak
   - if the disease presents an outbreak threat (e.g. measles, Salmonella, respiratory diseases in institutions)
2. to prevent spread
   - if the disease presents a significant threat to individuals or a subset of the population (e.g. Lassa Fever)
3. for surveillance
   - if the disease is preventable with immunization (e.g. polio, diphtheria, congenital rubella)
4. if infected individuals require education, treatment and/or partner notification (e.g. gonorrhea, TB)

Physicians should also report unlisted diseases that appear in clusters.

The following list is based on the reportable diseases in Ontario for 2011.
(Each province will have their own similar legislation)

**Source:** Health Protection and Promotion Act, O. Reg. 559/91, amended to O. Reg.49/07.

### Acquired Immunodeficiency Syndrome (AIDS)
### Amebiasis
### Anthrax
### Botulism
### Brucellosis
### Campylobacter enteritis
### Chancroid
### Chickenpox (Varicella)
### Chlamydia trachomatis infections
### Cholera
### Clostridium difficile associated disease (CDAD) outbreaks in public hospitals
### Cryptosporidiosis
### Cyclosporiasis
### Cytomegalovirus infection, congenital
### Diphtheria
### Encephalitis, including:
  i. Primary, viral
  ii. Post-infectious
  iii. Vaccine-related
  iv. Subacute sclerosing panencephalitis
  v. Unspecified
### Food poisoning, all causes
### Gastroenteritis, institutional outbreaks
### Giardiasis, except asymptomatic cases
### Gonorrhea
### Haemophilus influenzae b disease, invasive
### Hantavirus pulmonary syndrome
### Hemorrhagic fevers, including:
  i. Ebola virus disease
  ii. Marburg virus disease
  iii. Other viral causes
### Hepatitis, viral:
  i. Hepatitis A
  ii. Hepatitis B
  iii. Hepatitis C
  iv. Hepatitis D (Delta hepatitis)
### Herpes, neonatal
### HIV
### Influenza
### Lassa Fever
### Legionellosis
### Leprosy
### Lyme Disease
### Malaria
### Meningitis, acute:
  i. Bacterial
  ii. Viral
  iii. Other
### Meningococcal disease, invasive
### Mumps
### Ophthalmia neonatorum
### Paratyphoid fever
### Pertussis (whooping cough)
### Plague
### Poliomyelitis, acute
### Psittacosis/Ornithosis
### Q Fever
### Rabies
### Respiratory infection outbreaks in institutions
### Rubella
### Rubella, congenital syndrome
### Salmonellosis
### Severe Acute Respiratory Syndrome (SARS)
### Shigellosis
### Smallpox
### Streptococcal infections, Group A invasive
### Streptococcal infections, Group B neonatal
### Streptococcus pneumoniae, invasive syphilis
### Tetanus
### Transmissible spongiform encephalopathy, including:
  i. Creutzfeldt-Jakob disease, all types
  ii. Gerstmann-Sträussler-Scheinker syndrome
  iii. Fatal familial insomnia
  iv. Kuru
### Trichinosis
### Tuberculosis
### Tularemia
### Typhoid Fever
### Verotoxin-producing E. coli infection indicator conditions, including
### Hemolytic Uremic Syndrome (HUS)
### West Nile Virus illness, including:
  i. West Nile fever
  ii. West Nile neurological manifestations
### Yellow Fever
### Yersiniosis

Psychiatric Assessment

History

Identifying Data
- name, sex, age, ethnicity, marital status, religion, occupation, education, type of residence, with whom they are living, referral source

Reliability of Patient as a Historian
- may need collateral source (e.g. parent, teacher) if patient unable/unwilling to co-operate

Chief Complaint
- in patient's own words, duration

History of Present Illness
- reason for seeking help (that day), current symptoms (onset, duration and course), stressors, supports, functional status, relevant associated symptoms (pertinent positives and negatives)
- safety screen: is the patient endangering self or others? dependents at home (e.g. children, pets), ability to drive safely, ability to care for self (e.g. eating, hygiene, taking medications)

Psychiatric Functional Inquiry
- mood: depressed, manic
- anxiety: worries, obsessions, compulsions, panic attacks, phobias, history of trauma
- psychotic: hallucinations, delusions, thought form disorders
- suicide/homicide: ideation, plan, intent, history of attempts
- organic: EtOH/drug use or withdrawal, illness, dementia

Past Psychiatric History
- all previous psychiatric diagnoses, psychiatric contacts, treatments (pharmacological and non-pharmacological) and hospitalizations
- also include past suicide attempts, substance use/abuse, and legal problems

Past Medical/Surgical History
- all medical, surgical, neurological (e.g. head trauma, seizures), and psychosomatic illnesses
- medications, allergies

Family Psychiatric/Medical History
- family members: ages, occupations, personalities, medical or genetic illnesses and treatments, relationships with parents/siblings
- family psychiatric history: any past or current psychiatric illnesses and hospitalizations, suicide, substance abuse

Past Personal History
- prenatal and perinatal history (desired vs. unwanted pregnancy, maternal and fetal health, domestic violence, maternal substance use, complications of pregnancy/delivery)
- early childhood to age 3 (developmental milestones, activity/attention level, family stability, attachment figures)
- middle childhood to age 11 (school performance, peer relationships, fire-setting, stealing, incontinence)
- late childhood to adolescence (drug/alcohol, legal problems, peer and family relationships)
- physical or sexual abuse in childhood/adolescence
- adulthood (education, occupations, relationships)
- psychosexual history (paraphilias, gender roles, sexual abuse, sexual dysfunction)
- personality before current illness, recent changes in personality

N.B. The content in this chapter does not reflect the changes made to diagnostic criteria in the DSM-V
### Mental Status Exam (MSE)

#### General Appearance and Behaviour
- dress, grooming, posture, gait, physical characteristics, body habitus, apparent vs. chronological age, facial expression (e.g. sad, suspicious)
- psychomotor activity (agitation, retardation), abnormal movements or lack thereof (tremors, akathisia, tardive dyskinesia, paralysis), attention level and eye contact, attitude toward examiner (ability to interact, level of co-operation)

#### Speech
- rate (e.g. pressured, slowed), rhythm/fluency, volume, tone, articulation, quantity, spontaneity

#### Mood and Affect
- mood: subjective emotional state (in patient's own words)
- affect: objective emotional state inferred from emotional responses to stimuli. Described in terms of:
  - quality (euthymic, depressed, elevated, anxious)
  - range (full, restricted, flat, blunted)
  - stability (fixed, labile)
- mood congruence (inferred by reader by comparing mood and affect descriptions)
- appropriateness to thought content

#### Thought Process
- coherence (coherent, incoherent)
- logic (logical, illogical)
- stream
  - goal-directed
  - circumstantial: speech that is indirect and delayed in reaching its goal; eventually comes back to the point
  - tangential: speech is oblique or irrelevant; does not come back to the original point
  - loosening of associations: illogical shifting between topics
  - flight of ideas: quickly skipping from one idea to another where the ideas are marginally connected, associated with mania
- word salad: jumble of words lacking meaning or logical coherence
- perseveration: repetition of the same verbal or motor response to stimuli
- echolalia: repetition of phrases or words spoken by someone else
- thought blocking: sudden cessation of flow of thought and speech
- clang associations: speech based on sound such as rhyming or punning
- neologism: use of novel words or of existing words in a novel fashion

#### Thought Content
- suicidal ideation/homicidal ideation
  - frequency and perversiveness of thoughts, formulation of plan, means to plan, intent, active vs. passive, protective factors
- pre-occupations, ruminations: reflections/thoughts at length, not fixed or false
- obsession: recurrent and persistent thought, impulse or image which is intrusive or inappropriate
  - cannot be stopped by logic or reason
  - causes marked anxiety and distress
- common themes: contamination, orderliness, sexual, pathological doubt/worry/guilt
- magical thinking: belief that thinking something will make it happen; normal in children
- ideas of reference: similar to delusion (fixed false belief), but the reality of the belief is questioned
- overvalued ideas: unusual/odd beliefs that are not of delusional proportions
- first rank symptoms of schizophrenia: thought insertion/withdrawal/broadcasting
- delusion: a fixed false belief that is out of keeping with a person's cultural or religious background and is firmly held despite incontrovertible proof to the contrary

#### Perception
- hallucination: sensory perception in the absence of external stimuli that is similar in quality to a true perception
  - auditory (most common), visual, gustatory, olfactory, tactile
- illusion: misperception of a real external stimulus
- depersonalization: change in self-awareness such that the person feels unreal, detached from his or her body, and/or unable to feel emotion
- derealization: feeling that the world/outer environment is unreal

---

**Spectrum of Affect**

<table>
<thead>
<tr>
<th>Full</th>
<th>Restricted</th>
<th>Blunted</th>
<th>Flat</th>
</tr>
</thead>
</table>

There is poor correlation between clinical impression of suicide risk and frequency of attempts.

**Delusions**

- Persecutory: belief that others are trying to cause harm to you
- Reference: interpreting publicly known events/celebrities as having direct reference to you
- Erotomania: belief that another is in love with you
- Grandiose: an inflated sense of self-worth or power
- Religious: belief of receiving instructions/powers from a higher being; of being a higher being
- Somatic: belief that you have a physical disorder/defect
- Nihilistic: belief that things do not exist; a sense that everything is unreal

**Cognitive Assessment**

Use MMSE to assess:

- Orientation (time and place)
- Memory (immediate and delayed recall)
- Attention and concentration
- Language (comprehension, reading, writing, repetition, naming)
- Spatial ability (intersecting pentagons)

Gross screen for cognitive dysfunction:

Total score is out of 30: <24 abnormal, 20-24 mild, 10-19 moderate, <10 severe
Cognition
- level of consciousness
- orientation: time, place, person
- memory: immediate, recent, remote
- global evaluation of intellect (below average, average, above average)
- intellectual functions: attention, concentration, calculation, abstraction (proverb interpretation, similarities test), language, communication

Insight
- patient’s ability to realize that he or she has a physical or mental illness and to understand its implications

Judgement
- patient’s ability to understand relationships between facts and draw conclusions that determine one’s actions

Summary of Axes

Multiaxial Assessment
- Axis I
  - differential diagnosis of DSM-IV clinical disorders
- Axis II
  - personality disorders, developmental disability
- Axis III
  - general medical conditions that are potentially relevant to the understanding or management of the mental disorder
- Axis IV
  - psychosocial and environmental issues
- Axis V
  - Global Assessment of Functioning (GAF, 0 to 100) incorporating effects of axes I to IV

Formulation
- summary outlining current issues and interrelations between an individual’s biological, psychological, and social factors
- for each category: predisposing, precipitating, perpetuating, and protecting factors

Approach to Management
- biological (e.g. pharmacotherapy), psychological [e.g. cognitive behavioural therapy (CBT)], social (e.g. support group)

Suicide

Epidemiology
- attempted:completed = 20:1
- M:F = 1:4 for attempts, 3:1 for completed

Risk Factors
- epidemiologic factors
  - age: increases after age 14, second most common cause of death for ages 15-24, highest rates in persons >65 yr
  - sex: male
  - race/ethnic background: white or native Canadians on reserves
  - marital status: widowed/divorced
  - living situation: alone; no children <18 yr old in the household
  - other: stressful life events, access to firearms
- psychiatric disorders
  - mood disorders (15% lifetime risk in depression; higher in bipolar)
  - anxiety disorders (especially panic disorder)
  - schizophrenia (10-15% risk)
  - substance abuse (especially alcohol – 15% lifetime risk)
  - eating disorders (5% lifetime risk)
  - adjustment disorder
  - conduct disorder
  - personality disorders (borderline, antisocial)
- past history
  - prior suicide attempt
  - family history of suicide attempt/completion

Assessing Insight and Judgement
Insight
- Do you think that you have a mental illness?
- Why are you taking this medication?
- Why are you in the hospital?

Judgement
Can be observed from collected history and patient’s appearance and actions.
- Is he/she dressed appropriately for the weather?
- Is he/she acting appropriately in the given situation?
- Is he/she taking care of self and/or dependents?

Axis V: Global Assessment of Functioning
The description of each 10-point range in the GAF scale has two components: the first part covers symptom severity, and the second part covers functioning. It should be noted that in situations where the individual’s symptom severity and functioning are discordant, the final GAF rating always reflects the worse of the two.
91-100 Superior functioning in a wide range of activities
81-90 Absent or minimal symptoms
71-80 If symptoms are present, they are transient and expected reactions to psychosocial stressors
61-70 Some mild symptoms or some difficulty but generally functioning well
51-60 Moderate symptoms or difficulty
41-50 Serious symptoms or difficulty
31-40 Some impairment in reality testing/communication, impairment in several areas
21-30 Behaviour is influenced by delusions/hallucinations or serious impairment in communication/judgment
11-20 Some danger of hurting self or others or occasionally fails to maintain minimal hygiene or gross impairment in communication
1-10 Persistent danger of severely hurting self or others or persistent inability to maintain minimal personal hygiene or serious suicidal act
0 Inadequate information

Suicide Risk Factors
SAD PERSONS
Sex (male)
Age >60 yr old
Depression
Previous attempts
Ethanol abuse
Rational thinking loss (delusions, hallucinations, hopelessness)
Suicide in family
Organized plan
No spouse (no support systems)
Serious illness, intractable pain
Clinical Presentation
- symptoms associated with suicide:
  - hopelessness
  - anhedonia
  - insomnia
  - severe anxiety
  - impaired concentration
  - psychomotor agitation
  - panic attacks

Approach
Every Patient: “Have you had any thoughts of wanting to hurt or kill yourself?”
- passive ideation: would rather not be alive but has no active plan for suicide
  - e.g. “I’d rather not wake up” or “I would not mind if a car hit me”
- active ideation
  - e.g. “I think about killing myself”
- plan: “Do you have a plan as to how you would end your life?”
- intent: “You talk about wanting to die, but are you planning to do this?” or “What has stopped you from ending your life?”
- past attempts: highest risk if previous attempt in past year
  - ask about lethality, outcome, medical intervention

Assessment of Suicidal Ideation
- onset and frequency of thoughts: “When did this start?” or “How often do you have these thoughts?”
- control over suicidal ideation: “Can you stop the thoughts or call someone for help?”
- lethality: “Do you want to end your life?” or “What do you think would happen if you actually took those pills?”
- access to means: “How will you get a gun?” or “Which bridge do you think you would go to?”
- time and place: “Have you picked a date and place? Is it in an isolated location?”
- provocative factors: “What makes you feel worse (e.g. being alone)?”
- protective factors: “What keeps you alive (e.g. friends, family, pets, faith, therapist)?”
- final arrangements: “Have you written a suicide note? Made a will? Given away your belongings?”
- practiced suicide or aborted attempts: “Have you put the gun to your head?” “Held the medications in your hand?” “Stood at the bridge?”
- ambivalence: “There must be a part of you that wants to live, after all you came here for help”

Assessment of Suicide Attempt
- setting (isolated vs. others present, chance of discovery)
- planned vs. impulsive attempt, triggers/stressors
- intoxication
- medical attention (brought in by another person vs. brought in by self to ER)
- time lag from suicide attempt to ER arrival
- expectation of lethality, dying
- reaction to survival (guilt/remorse vs. disappointment/self-blame)

Management
- proper documentation of the clinical encounter and rationale for management is essential
- higher risk (hospitalization needs to be strongly considered)
  - patients with a plan, access to lethal means, recent social stressors, and symptoms suggestive of a psychiatric disorder
  - do not leave patient alone; remove potentially dangerous objects from room
  - if patient refuses to be hospitalized, complete form for involuntary admission (Form 1)
- lower risk
  - patients who are not actively suicidal, with no plan or access to lethal means
  - discuss protective factors and supports in their life, remind them of what they live for, promote survival skills that helped them through previous suicide attempts
  - make a safety plan: an agreement that they will:
    - not harm themselves
    - avoid alcohol, drugs, and situations that may trigger suicidal thoughts
    - follow-up with you at a designated time
    - contact a health care worker, call a crisis line or go to an emergency department if they feel unsafe or if their suicidal feelings return or intensify
  - depression: consider hospitalization if symptoms severe or if psychotic features are present; otherwise outpatient treatment with good supports and SSRIs/SNRIs
  - alcohol-related: usually resolves with abstinence for a few days; if not, suspect depression
  - personality disorders: crisis intervention/confrontation, may or may not hospitalize
  - schizophrenia/psychosis: hospitalization might be necessary
  - parasuicide/self-mutilation: long-term psychotherapy with brief crisis intervention when necessary

Pharmacotherapy and Suicide Risk
Once antidepressant therapy is initiated, patients should be followed frequently as there is a “suicide window” in which the patient may still be depressed, but now has enough energy to carry out suicide. Avoid tricyclic antidepressants (TCAs) because of high lethality in overdose!
**Psychotic Disorders**

**Definition**
- characterized by a significant impairment in reality testing
  - delusions or hallucinations (with/without insight into their pathological nature)
  - behaviour so disorganized that it is reasonable to infer that reality testing is disturbed

**Table 1. Differentiating Psychotic Disorders**

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Psychotic Symptoms</th>
<th>Duration</th>

<tr>
<td>2º to mood disorder</td>
<td>Delusions/hallucinations (mood congruent)</td>
<td>Unspecified</td>
</tr>
</tbody>
</table>

**Differential Diagnosis of Psychosis**
- primary psychotic disorders: schizophrenia, schizophreniform, brief psychotic, schizoaffective, shared psychotic, delusional disorder
- mood disorders: depression with psychotic features, bipolar disorder (mania or depression with psychotic features)
- personality disorders: schizotypal, schizoid, borderline, paranoid, obsessive-compulsive
- general medical conditions: tumour, head trauma, dementia, delirium, metabolic, infection, stroke, temporal lobe epilepsy
- substance-induced psychosis: intoxication or withdrawal, prescribed medications, toxins

**Schizophrenia**

**DSM-IV-TR Diagnostic Criteria for Schizophrenia**

A. characteristic symptoms (active phase): ≥2 of the following, each present for a significant portion of time during a 1-mo period (or less if successfully treated)
- delusions
- hallucinations
- disorganized speech (e.g. frequent derailment or incoherence)
- grossly disorganized or catatonic behaviour
- negative symptoms [e.g. affective flattening, alogia (inability to speak), or avolition (inability to initiate and persist in goal-directed activities)]

Note: only 1 "A" symptom is required if delusions are bizarre or hallucinations consist of a voice keeping a running commentary on the person's behaviour or thoughts, or 2 or more voices conversing with each other

B. social/occupational dysfunction: ≥1 major areas of functioning (work, interpersonal relations, self-care) markedly below the level achieved prior to the onset of symptoms

C. continuous signs of disturbance for ≥6 mo, including ≥1 mo of active phase symptoms; may include prodromal or residual phases

D. schizoaffective and mood disorders excluded

E. the disturbance is not due to the direct physiological effects of a substance or a GMC

F. if history of pervasive developmental disorder, additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations are also present for at least 1 mo

**Subtypes**
- paranoid
  - preoccupation with delusions (typically persecutory or grandiose) or frequent auditory hallucinations
  - relative preservation of cognitive functioning and affect; onset tends to be later in life; believed to have the best prognosis
• catatonic
  ▪ at least two of: motor immobility (catalepsy or stupor); excessive motor activity (purposeless); extreme negativism (resistance to instructions/Attempts to be moved) or mutism; peculiar voluntary movement (posturing, stereotyped movements, prominent mannerisms); echolalia or echopraxia (copying another’s speech or movements)
• disorganized
  ▪ disorganized speech and behaviour; flat or inappropriate affect
  ▪ poor premorbid personality, early and insidious onset, and continuous course without significant remissions
• undifferentiated
  ▪ meets criteria for schizophrenia, but does not fall into the 3 previous subtypes
  ▪ residual
  ▪ no longer have prominent delusions, hallucinations, disorganized speech, grossly disorganized or catatonic behaviour
  ▪ continuing evidence of residual illness such as negative symptoms or attenuated symptoms of criteria A

Epidemiology
• prevalence: 0.5%-1%; M:F = 1:1
• mean age of onset: females ~27; males ~21

Etiology
• multifactorial: disorder is a result of interaction between both biological and environmental factors
  ▪ genetic: 40% concordance in monozygotic (MZ) twins; 46% if both parents have schizophrenia; 10% of dizygotic (DZ) twins, siblings, children affected
  ▪ neurochemistry (“dopamine hypothesis” theory): excess activity in the mesolimbic dopamine pathway may mediate the positive symptoms of psychosis while decreased dopamine in the prefrontal cortex may mediate negative and cognitive symptoms. GABA, glutamate and ACh dysfunction are also thought to be involved
  ▪ neuroanatomy: decreased frontal lobe function; asymmetric temporal/limbic function; decreased basal ganglia function; subtle changes in thalamus, cortex, corpus callosum, and ventricles; cytoarchitectural abnormalities
  ▪ neuroendocrinology: abnormal growth hormone, prolactin, cortisol, and ACTH
  ▪ neuropsychology: global defects seen in attention, language, and memory suggest lack of connectivity of neural networks
  ▪ environmental: indirect evidence of cannabis use, geographical variance, winter season of birth, obstetrical complications, and prenatal viral exposure

Pathophysiology
• neurodegenerative theory
  ▪ natural history may be a rapid or gradual decline in function and ability to communicate
  ▪ glutamate system may mediate progressive degeneration by excitotoxic mechanism which leads to production of free radicals
• neurodevelopmental theory: abnormal development of the brain from prenatal life
  ▪ neurons fail to migrate correctly, make inappropriate connections, and break down in later life
  ▪ inappropriate apoptosis during neurodevelopment resulting in faulty connections between neurons

Management of Schizophrenia
• biological
  ▪ acute treatment and maintenance with antipsychotics ± anticonvulsants ± anxiolytics
• psychosocial
  ▪ psychotherapy (individual, family, group): supportive, CBT (see CBT, PS41)
  ▪ assertive community treatment (ACT): mobile mental health teams that provide individualized treatment in the community and help patients with medication adherence, basic living skills, social support, job placements, and community resources
  ▪ social skills training, employment programs, disability benefits
  ▪ housing (group home, boarding home, transitional home)

Course and Prognosis
• the majority of individuals display some type of prodromal phase
• course is variable: some individuals have exacerbations and remissions and others remain chronically ill; accurate prediction of the long term outcome is not possible
• early in the illness, negative symptoms may be prominent; positive symptoms appear and typically diminish with treatment; negative symptoms may become more prominent and more disabling
• over time: 1/3 improve, 1/3 remain the same, 1/3 worsen
Schizophreniform Disorder

- **diagnosis**: criteria A, D and E of schizophrenia are met; an episode of the disorder lasts from 1-6 mo. If the symptoms have extended past 6 mo the diagnosis becomes schizophrenia
- **treatment**: similar to acute schizophrenia
- **prognosis**: better than schizophrenia; begins and ends more abruptly; good pre- and post-morbid function

Brief Psychotic Disorder

- **diagnosis**: acute psychosis (presence of 1 or more positive symptoms in criteria A 1-4 of schizophrenia) lasting from 1 day to 1 mo, with eventual full return to premorbid level of functioning
- can occur after a stressful event or postpartum (see Postpartum Mood Disorders, PS12)
- **treatment**: secure environment, antipsychotics, anxiolytics
- **prognosis**: good, self-limiting, should return to pre-morbid function in about 1 mo

Schizoaffective Disorder

**DSM-IV-TR Diagnostic Criteria for Schizoaffective Disorder**

A. **uninterrupted period of illness during which there is either a MDE, manic episode, or a mixed episode concurrent with symptoms meeting criteria A for schizophrenia**

B. **in the same period, delusions or hallucinations for ≥2 wk in the absence of prominent mood symptoms**

C. **symptoms that meet criteria for a mood episode are present for a substantial portion of total duration of active and residual periods of the illness**

D. **the disturbance is not due to the direct physiological effects of a substance or GMC**

- **treatment**: antipsychotics, mood stabilizers, antidepressants
- **prognosis**: between that of schizophrenia and of mood disorder

Delusional Disorder

**DSM-IV-TR Diagnostic Criteria for Delusional Disorder**

A. **non-bizarre delusions for ≥1 mo**

B. **criterion A for schizophrenia has never been met (though patient may have tactile or olfactory hallucinations if they are related to the delusional theme)**

C. **functioning not markedly impaired; behaviour not obviously odd or bizarre**

D. **if mood episodes occur concurrently with delusions, total duration has been brief relative to duration of the delusional periods**

E. **the disturbance is not due to the direct physiological effects of a substance or GMC**

- **subtypes**: erotomanic, grandiose, jealous, persecutory, somatic, mixed, unspecified
- **treatment**: psychotherapy, antipsychotics, antidepressants
- **prognosis**: chronic, unremitting course but high level of functioning

Shared Psychotic Disorder (Folie à Deux)

- **diagnosis**: delusion that develops in an individual who is in a close relationship with another person who already has a psychotic disorder with prominent delusions; the delusion is similar in content to that of the other person
- **treatment**: separation of the two people results in the disappearance of the delusion in the healthier member; antipsychotics may play a role
- **prognosis**: good
Mood Disorders

Definitions
- Mood disorders are defined by the presence of mood episodes
- Mood episodes represent a combination of symptoms comprising a predominant mood state that is abnormal in quality or duration (e.g., major depressive, manic, mixed, hypomanic)
- Types of mood disorders include:
  - Depressive (major depressive disorder, dysthymia)
  - Bipolar (bipolar I/II disorder, cyclothymia)
  - Secondary to GMC, substances, medications

Table 2. Secondary Causes of Mood Disorders

Medical Workup of Mood Disorder
- Routine screening: physical examination, CBC, thyroid function test, electrolytes, extended electrolytes, urinalysis, drug screen
- Additional screening: neurological consultation, chest x-ray, ECG, CT

Mood Episodes

DSM-IV-TR Criteria for Major Depressive Episode
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Text Revision, Fourth Edition (Copyright 2000), American Psychiatric Association.

A. ≥ 5 of the following symptoms have been present during the same 2-wk period and represent a change from previous functioning; at least one of the symptoms is either 1) depressed mood or 2) loss of interest or pleasure (anhedonia)

Note: Do not include symptoms that are clearly due to a GMC, mood-incongruent delusions or hallucinations
- Depressed mood most of the day, nearly every day, as indicated by either subjective report or observation made by others
- Markedly diminished interest or pleasure in all or almost all activities most of the day, nearly every day
- Significant weight loss when not dieting or weight gain, or decrease or increase in appetite nearly every day
- Insomnia or hypersomnia nearly every day
- Psychomotor agitation or retardation nearly every day
- Fatigue or loss of energy nearly every day
- Feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick)
- Recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide

B. The symptoms do not meet criteria for a mixed episode (see PS10)

C. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

D. The symptoms are not due to the direct physiological effects of a substance or a GMC

E. The symptoms are not better accounted for by bereavement; the symptoms persist for longer than 2 mo; symptoms are characterized by marked functional impairment, morbid preoccupation with worthlessness, suicidal ideation, psychotic symptoms, or psychomotor retardation
DSM-IV-TR Criteria for Manic Episode

A. a distinct period of abnormally and persistently elevated, expansive, or irritable mood, lasting ≥1 wk (or any duration if hospitalization is necessary) (note: in DSM-5, “persistently increased goal-directed activity or energy” has been added to criteria A)

B. during the period of mood disturbance, ≥3 of the following symptoms have persisted (4 if the mood is only irritable) and have been present to a significant degree:

- inflated self-esteem or grandiosity
- decreased need for sleep (e.g. feels rested after only 3 h of sleep)
- more talkative than usual or pressure to keep talking
- flight of ideas or subjective experience that thoughts are racing
- distractibility (i.e. attention too easily drawn to unimportant or irrelevant external stimuli)
- increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation
- excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g. engaging in unrestrained shopping sprees, sexual indiscretions, or foolish business investments)

C. the symptoms do not meet criteria for a mixed episode (see below)

D. the mood disturbance is sufficiently severe to cause marked impairment in occupational functioning or in usual social activities or relationships with others, or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features

E. the symptoms are not due to the direct physiological effects of a substance (e.g. drug of abuse, medication, or other treatment) or a GMC (e.g. hyperthyroidism).

Note: Manic-like episodes that are clearly caused by somatic antidepressant treatment (e.g. medication, ECT therapy, light therapy) should not count toward a diagnosis of Bipolar I Disorder (this has been removed in DSM-5)

Mixed Episode
- criterion met for both manic episode and MDE nearly every day for 1 wk
- criteria D and E of manic episodes are met

Note: in DSM-5, mixed episode is no longer a separate mood diagnosis; instead, depressed episodes and manic episodes can have a “with mixed features” specifier

Hypomanic Episode
- criterion A of a manic episode is met, but duration is ≥4 d
- criteria B and E of manic episodes are met
- episode associated with an uncharacteristic decline in functioning that is observable by others
- change in function is not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization
- absence of psychotic features

Depressive Disorders

MAJOR DEPRESSIVE DISORDER

DSM-IV-TR Diagnostic Criteria for Major Depressive Disorder (MDD), Single Episode (vs. Recurrent)

A. presence of a single MDE (vs. recurrent, which requires presence of two or more MDEs; to be considered separate episodes, there must be an interval of at least 2 consecutive months in which criteria are not met for a MDE)

B. the MDE is not better accounted for by Schizoaffective Disorder and is not superimposed on Schizophrenia, Schizophreniform Disorder, Delusional Disorder, or Psychotic Disorder NOS

C. there has never been a Manic Episode, a Mixed Episode, or a Hypomanic Episode

Note: This exclusion does not apply if all of the manic-like, mixed-like, or hypomanic-like episodes are substance or treatment-induced or are due to the direct physiological effects of a GMC

Features/Specifiers
- psychotic: with hallucinations or delusions
- chronic: lasting 2 yr or more
- catatonic: at least two of: motor immobility, excessive motor activity, extreme negativism or mutism, peculiarities of voluntary movement, echolalia or echopraxia
- melancholic: quality of mood is distinctly depressed, mood is worse in the morning, early morning awakening, marked weight loss, excessive guilt, psychomotor retardation
- atypical: increased sleep, weight gain, leaden paralysis, rejection hypersensitivity
- postpartum: (see Postpartum Mood Disorders, PS12)
- seasonal: pattern of onset at the same time each year (most often in the fall or winter)

Note: in DSM-5 the specifiers have changed to include: with anxious distress, with mixed features, with melancholic features, with atypical features, with mood-congruent psychotic features, with mood-incongruent psychotic features, with catatonia, with peripartum onset, with seasonal pattern
Epidemiology
- prevalence: 12.2%
  - lifetime prevalence: male 2.9%, female 5%
  - annual prevalence: peak prevalence age 15-25 yr (M:F = 1:2)

Etiology
- biological
  - genetic: 65-75% MZ twins; 14-19% DZ twins
  - neurotransmitter dysfunction: decreased activity of 5HT, NE and DA at the level of the synapse; changes in GABA and glutamate; changes in brain circuitry
  - neuroendocrine dysfunction: increased production of corticotropin causing excessive HPA axis activity
  - neuroanatomy: smaller frontal lobes and hippocampal volume; increased ventricle sizes
  - neurophysiologic: decreased REM latency and slow-wave sleep; increased REM length
  - secondary to GMC
- psychosocial
  - psychodynamic (e.g. low self-esteem)
  - cognitive (e.g. negative thinking)
  - environmental factors (e.g. job loss, bereavement, history of abuse, early life adversity)
  - co-morbid psychiatric diagnoses (e.g. anxiety, substance abuse, developmental disability, dementia, eating disorder)

Risk Factors
- sex: female > male
- age: onset between 25-50 yr of age
- family history: depression, alcohol abuse, sociopathy
- childhood experiences: loss of parent before age 11, negative home environment (abuse, neglect)
- personality: insecure, dependent, obsessional
- recent stressors: illness, financial, legal
- postpartum <6 mo
- lack of intimate, confiding relationships or social isolation

Depression in the Elderly
- affects about 15% of community residents >65 yr old; up to 50% in nursing homes
- high suicide risk due to social isolation, chronic medical illness
- suicide peak: males aged 80-90; females aged 50-65
- dysphoria may not be a reliable indicator of depression in those >85 yr
- often present with somatic complaints (e.g. changes in weight, sleep, energy) or anxiety symptoms
- may have prominent cognitive changes after onset of mood symptoms (dementia syndrome of depression)
- refer to Table 4 (see Dementia, PS21) to compare with delirium and dementia

Treatment
- biological: antidepressants primarily; could also consider lithium, antipsychotics, anxiolytics, light therapy, ECT, repetitive transcranial magnetic stimulation (rTMS)
- psychological
  - individual therapy (psychodynamic, interpersonal, CBT), family therapy, group therapy
  - social: vocational rehabilitation, social skills training
  - experimental: magnetic stimulation therapy (MST), deep brain stimulation, vagal nerve stimulation
- studies suggest CBT with pharmacotherapy results in better outcomes

Prognosis
- one year after diagnosis of a MDE without treatment: 40% of individuals still have symptoms that are sufficiently severe to meet criteria for a full MDE, 20% continue to have some symptoms that no longer meet criteria for a MDE, 40% have no mood disorder

DYSTHYMIA

DSM-IV-TR Diagnostic Criteria for Dysthymic Disorder
Note: in DSM-5 this has been changed to Persistent Depressive Disorder

A. depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for ≥2 yr
- Note: In children and adolescents, mood can be irritable and duration must be at least 1 yr
B. presence, while depressed, of ≥2 of the following
  - poor appetite or overeating
  - insomnia or hypersomnia
  - low energy or fatigue
- low self-esteem
- poor concentration or difficulty making decisions
- feelings of hopelessness

C. during the 2-yr period (1 yr for children or adolescents) of the disturbance, the person has never been without the symptoms in criteria A and B for more than 2 mo at a time

D. no MDE has been present during the first 2 yr of the disturbance (1 yr for children and adolescents); i.e. the disturbance is not better accounted for by chronic MDD, or MDD in partial remission

E. there has never been a Manic Episode, a Mixed Episode, or a Hypomanic Episode, and criteria have never been met for Cyclothymic Disorder

F. the disturbance does not occur exclusively during the course of a chronic psychotic disorder, such as Schizophrenia or Delusional Disorder

G. the symptoms are not due to the direct physiological effects of a substance or a GMC

H. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

**Epidemiology**
- point prevalence: 3%; life prevalence: 6%; M:F = 1:2-3

**Treatment**
- psychological
  - principal treatment for dysthymia
  - individual, group, and family therapy
- biological
  - antidepressant therapy (SSRIs/SNRIs) as an outpatient

---

### Postpartum Mood Disorders

**Postpartum “Blues”**
- transient period of mild depression, mood instability, anxiety, decreased concentration, increased concern over own health and health of baby – considered to be normal emotional changes related to the puerperium
- occurs in 50-80% of mothers; begins 2-4 d postpartum, usually lasts 48 h, can last up to 10 d
- does not require psychotropic medication
- patient at increased risk of developing postpartum depression

**Postpartum Depression (PPD)**
- diagnosis: MDE, onset within 4 wk postpartum
- clinical presentation:
  - typically lasts 2 to 6 mo; residual symptoms can last up to 1 yr
  - may present with psychosis – rare (0.2%), usually associated with mania, but also with MDE
  - severe symptoms include extreme disinterest in baby, suicidal and infanticidal ideation
- epidemiology: occurs in 10% of mothers, risk of recurrence 50%
- risk factors:
  - previous history of a mood disorder (postpartum or otherwise)
  - psychosocial factors: stressful life events, unemployment, marital conflict, lack of social support, unwanted pregnancy, colicky or sick infant
- treatment:
  - psychotherapy (CBT or IPT)
  - short-term safety of maternal SSRIs for breastfeeding infants established; long-term effects unknown
  - if depression severe, consider ECT
- prognosis:
  - impact on child development: increased risk of cognitive delay, insecure attachment, behavioural disorders
  - treatment of mother improves outcome for child at 8 mo through increased mother-child interaction

---

### Bipolar Disorders

**BIPOLAR I / BIPOLAR II DISORDER**

**Definition**
- Bipolar I Disorder
  - disorder in which at least one manic or mixed episode has occurred
  - commonly accompanied by at least 1 MDE but not required for diagnosis
- Bipolar II Disorder
  - disorder in which there is at least 1 MDE and at least 1 hypomanic episode
  - no past manic or mixed episodes
**Epidemiology**
- prevalence: 0.6-0.9%; M:F = 1:1
- age of onset: teens to 20's

**Risk Factors**
- high SES
- genetic: 60-65% of bipolar patients have family history of major mood disorders

**Classification**
- classification of bipolar disorder involves describing the current or most recent mood episode as either manic, hypomanic, mixed or depressed
- the current or most recent episode can be further classified as without psychotic features, with psychotic features, with catatonic features, with postpartum onset, with seasonal pattern, with rapid cycling (at least 4 episodes of a mood disturbance in the previous 12 mo that meet criteria for a major depressive, manic, mixed, or hypomanic episode)

**Treatment**
- biological: lithium, anticonvulsants, antipsychotics, antidepressants, ECT
- psychological: supportive or psychodynamic psychotherapy, CBT, ITP or interpersonal social rhythm therapy
- social: vocational rehabilitation, consider leave of absence from school/work, consider substitute decision maker for finances, drug and EtOH cessation, sleep hygiene, social skills training, education for family members

**Course and Prognosis**
- high suicide rate (15% mortality from suicide)
- relapsing and remitting course with alternating manic and depressive episodes; depressive symptoms tend to occur more frequently and last longer than manic episodes
- patients spend almost half of their lives symptomatic
- may switch rapidly between depression and mania without any period of euthymia in between
- high recurrence rate for mania – 90% will have a subsequent episode in the next 5 yr

**CYCLOTHYMIA**

**Diagnosis**
- presence of numerous periods of hypomanic and depressive symptoms (not meeting criteria for MDE) for ≥2 yr; never without symptoms for >2 mo
- no MDE, manic or mixed episodes, no evidence of psychosis
- symptoms are not due to the direct physiological effects of a substance or GMC
- symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

**Treatment**
- similar to Bipolar I: anticonvulsants ± psychotherapy

---

**Anxiety Disorders**

**Definition**
- anxiety is a universal human characteristic involving tension, apprehension, or even terror
- serves as an adaptive mechanism to warn about an external threat by activating the sympathetic nervous system (fight or flight)
- manifestations of anxiety can be described through:
  - physiology: main brain structure involved is the amygdala (fear conditioning); neurotransmitters involved include 5-HT, cholecystokinin, epinephrine, norepinephrine, DA
  - psychology: one's perception of a given situation is distorted which causes one to believe it is threatening in some way
  - behaviour: once feeling threatened, one responds by escaping or facing the situation, thereby causing a disruption in daily functioning
- anxiety becomes pathological when:
  - fear is greatly out of proportion to risk/severity of threat
  - response continues beyond existence of threat or becomes generalized to other similar or dissimilar situations
  - social or occupational functioning is impaired
Differential Diagnosis

Medical Workup of Anxiety Disorder
- routine screening: physical examination, CBC, thyroid function test, electrolytes, urinalysis, urine drug screening
- additional screening: neurological consultation, chest x-ray, ECG, CT

Panic Disorder

DSM-IV-TR Diagnostic Criteria for Panic Disorder without Agoraphobia

A. both (1) and (2)
- (1) recurrent unexpected panic attacks: a discrete period of intense fear or discomfort, in which ≥4 of the following symptoms develop abruptly and reach a peak within 10 min
  - palpitations, pounding heart, or accelerated heart rate
  - sweating
  - trembling or shaking
  - sensations of shortness of breath or smothering
  - feeling of choking
  - chest pain or discomfort
  - nausea or abdominal distress
  - feeling dizzy, unsteady, lightheaded, or faint
  - derealization (feelings of unreality) or depersonalization (being detached from oneself)
  - fear of losing control or going crazy
  - fear of dying
  - paresthesias (numbness or tingling sensations), chills or hot flushes
- (2) at least one of the attacks has been followed by 1 mo (or more) of ≥1 of the following
  - persistent concern about having additional attacks
  - worry about the implications of the attack or its consequences (e.g. losing control, having a heart attack, “going crazy”)
  - a significant change in behaviour related to the attacks

B. absence of agoraphobia
C. the panic attacks are not due to the direct physiological effects of a substance or GMC
D. the panic attacks are not better accounted for by another mental disorder, such as social phobia, specific phobia, obsessive-compulsive disorder, post-traumatic stress disorder, separation anxiety disorder

Epidemiology
- prevalence: 1.5-5% (one of the top five most common reasons to see a family doctor); M:F = 1.2-3
- onset: average late 20’s, familial pattern

Treatment
- psychological
  - CBT: interoceptive exposure (eliciting symptoms of a panic attack and learning to tolerate the symptoms without coping strategies); cognitive restructuring (addressing underlying beliefs regarding the panic attacks), relaxation techniques (visualization, box-breathing)
- pharmacological
  - SSRIs: fluoxetine, citalopram, paroxetine, fluvoxamine, sertraline
  - SNRIs: venlafaxine
  - with SSRIs/SNRIs start with low doses, titrate up slowly
  - anxiety disorders often require treatment at higher doses for a longer period of time (i.e. up to 8-12 wk than used for depression)
  - to prevent non-compliance due to physical side effects, explain symptoms to expect prior to initiation of therapy
  - other antidepressants (TCAs, mirtazapine, MAOIs)
    - consider avoiding bupropion due to stimulating effects
  - benzodiazepines (short term, low dose, regular schedule, long half-life, avoid prn use)
Prognosis
- 6-10 yr post-treatment: 30% well, 40-50% improved, 20-30% no change or worse
- clinical course: chronic, but episodic with psychosocial stressors

Panic Disorder with Agoraphobia
- agoraphobia
  - anxiety about being in places or situations from which escape might be difficult (or embarrassing) or where help may not be available in the event of having an unexpected panic attack
  - fears commonly involve situations such as being out alone, being in a crowd, standing in a line, or travelling on a bus
- situations are avoided, endured with anxiety or panic, or require companion
- treatment: as per panic disorder

Generalized Anxiety Disorder (GAD)

DSM-IV-TR Diagnostic Criteria for Generalized Anxiety Disorder

A. excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance)
B. the person finds it difficult to control the worry
C. the anxiety and worry are associated with ≥3 of the following 6 symptoms (with at least some symptoms present for more days than not for the past 6 mo)
  - restlessness or feeling keyed up or on edge
  - being easily fatigued
  - difficulty concentrating or mind going blank
  - irritability
  - muscle tension
  - sleep disturbance (difficulty falling or staying asleep, or restless unsatisfying sleep)
D. the focus of the anxiety and worry is not confined to features of an Axis I disorder, such as panic disorder, social phobia, etc.
E. the anxiety, worry, or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
F. the disturbance is not due to the direct physiological effects of a substance or a GMC and does not occur exclusively during a Mood Disorder, a Psychotic Disorder, or a Pervasive Developmental Disorder

Epidemiology
- 1-yr prevalence: 3-8%; M:F = 1:2
  - if considering only those receiving inpatient treatment, ratio is 1:1
- most commonly presents in early adulthood

Treatment
- lifestyle: caffeine and EtOH avoidance, sleep hygiene
- psychological: CBT including relaxation techniques, mindfulness
- biological
  - SSRIs and SNRIs are 1st line (paroxetine, escitalopram, sertraline, venlafaxine XL)
  - 2nd line: bupropion (caution due to stimulating effects ), buspirone (tid dosing)
  - add-on benzodiazepines (short term, low dose, regular schedule, long half-life, avoid prn)
  - β-blockers not recommended

Prognosis
- chronically anxious adults become less so with age
- depends on pre-morbid personality functioning, stability of relationships, work, and severity of environmental stress
- difficult to treat

Phobic Disorders

Specific Phobia
- definition: marked and persistent fear that is excessive or unreasonable, cued by presence or anticipation of a specific object or situation
- lifetime prevalence 12-16%; M:F ratio variable
- types: animal/insect, environment (heights, storms), blood/injection/injury, situational (airplane, closed spaces), other (loud noise, clowns)
Social Phobia (Social Anxiety Disorder)
- definition: marked and persistent fear of social or performance situations in which one is exposed to unfamiliar people or to possible scrutiny by others; fearing he/she will act in a way that may be humiliating or embarrassing (e.g. public speaking, initiating or maintaining conversation, dating, eating in public)
- lifetime prevalence may be as high as 13-16%; F>M

Diagnostic Criteria for Phobic Disorders
- exposure to stimulus almost invariably provokes an immediate anxiety response; may present as a panic attack
- person recognizes fear as excessive or unreasonable
- situations are avoided or endured with anxiety/distress
- significant interference with daily routine, occupational/social functioning, and/or marked distress
- if person is <18 yr, duration is at least 6 mo

Treatment
- psychological
  - cognitive behaviour therapy (focusing on both in vivo and virtual exposure therapy – gradually facing feared situations)
  - behavioural therapy is more efficacious than medication
- biological
  - β-blockers or benzodiazepines in acute situations (e.g. public speaking)

Prognosis
- chronic

Obsessive-Compulsive Disorder (OCD)

DSM-IV-TR Diagnostic Criteria for Obsessive Compulsive Disorder
A. either obsessions or compulsions:
  - obsessions as defined by (1), (2), (3), and (4)
    1. recurrent and persistent thoughts, impulses, or images that are experienced, at some time during the disturbance, as intrusive and inappropriate and that cause marked anxiety or distress
    2. the thoughts, impulses, or images are not simply excessive worries about real-life problems
    3. the person attempts to ignore or suppress such thoughts, impulses, or images, or to neutralize them with some other thought or action
    4. the person recognizes that the obsessional thoughts, impulses, or images are a product of his or her own mind (not imposed)
  - compulsions as defined by (1) and (2)
    1. repetitive behaviours or mental acts that the person feels driven to perform in response to an obsession, or according to rules that must be applied rigidly
    2. the behaviours or mental acts are aimed at preventing or reducing distress or preventing some dreaded event or situation; however, these behaviours or mental acts either are not connected in a realistic way with what they are designed to neutralize/prevent or are clearly excessive
B. at some point during the course of the disorder, the person has recognized that the obsessions or compulsions are excessive or unreasonable (ego-dystonic)
Note: This does not apply to children
C. the obsessions or compulsions cause marked distress, are time-consuming (take ≥1 h a day), or significantly interfere with the person’s normal routine, occupational (or academic) functioning, or usual social activities or relationships
D. if another Axis I disorder is present, the content of the obsessions or compulsions is not restricted to it (e.g. preoccupation with food in the presence of an Eating Disorder)
E. the disturbance is not due to the direct physiological effects of a substance or a GMC

Epidemiology
- lifetime prevalence rates 2-3%; M=F
- rate of OCD in first-degree relatives is higher than in the general population

Treatment
- CBT: exposure with response prevention (ERP) – involves exposure to feared situations with the addition of preventing the compulsive behaviours; cognitive strategies include challenging underlying beliefs
- pharmacotherapy: SSRIs/SNRIs, clomipramine; adjunctive risperidone

Prognosis
- tends to be refractory and chronic
Post-Traumatic Stress Disorder (PTSD)

DSM-IV-TR Diagnostic Criteria for Post-Traumatic Stress Disorder

A. the person has been exposed to a traumatic event in which both of the following were present
   (1) the person experienced, witnessed, or was confronted with an event or events that
      involved actual or threatened death or serious injury, or a threat to the physical integrity
      of self or others
   (2) the person's response involved intense fear, helplessness, or horror
      Note: in children, this may be expressed instead by disorganized or agitated behaviour
B. the traumatic event is persistently re-experienced in one (or more) of the following ways:
   (1) recurrent and intrusive distressing recollections of the event, including images, thoughts,
      or perceptions
      Note: in children, repetitive play may occur in which themes or aspects of the trauma are
      expressed
   (2) recurrent distressing dreams of the event
      Note: in children, there may be frightening dreams without recognizable content
   (3) acting or feeling as if the traumatic event were recurring (includes a sense of reliving the
      experience, illusions, hallucinations, and dissociative flashback episodes, including those
      that occur on awakening or when intoxicated)
      Note: in children, trauma-specific reenactment may occur
   (4) intense psychological distress at exposure to internal or external cues that symbolize or
      resemble an aspect of the traumatic event
   (5) physiological reactivity on exposure to internal or external cues that symbolize or
      resemble an aspect of the traumatic event
C. persistent avoidance of stimuli associated with the trauma and numbing of general
   responsiveness (not present before the trauma), as indicated by ≥3 of the following:
   (1) efforts to avoid thoughts, feelings, or conversations associated with the trauma
   (2) efforts to avoid activities, places, or people that arouse recollections of the trauma
   (3) inability to recall an important aspect of the trauma
   (4) markedly diminished interest or participation in significant activities
   (5) feeling of detachment or estrangement from others
   (6) restricted range of affect (e.g. unable to have loving feelings)
   (7) sense of a foreshortened future (e.g. does not expect to have a career, marriage, children,
      or a normal life span)
D. persistent symptoms of increased arousal (not present before the trauma), as indicated by ≥2 of
   the following:
   (1) difficulty falling or staying asleep
   (2) irritability or outbursts of anger
   (3) difficulty concentrating
   (4) hypervigilance
   (5) exaggerated startle response
E. duration of the disturbance (symptoms in Criteria B, C, and D) is ≥1 mo
F. the disturbance causes clinically significant distress or impairment in social, occupational, or
   other important areas of functioning

Epidemiology
• prevalence in general population: 7%
• men's trauma is most commonly combat experience/physical assault; women's trauma is usually
  physical or sexual assault

Treatment
• CBT: exposure therapy, challenge dysfunctional beliefs, emotional regulation techniques (e.g.
  breathing, relaxation)
• biological
  • SSRIs
  • benzodiazepines (for acute anxiety)
  • adjunctive atypical antipsychotics (risperidone, olanzapine)
• Eye Movement Desensitization and Reprocessing (EMDR); an experimental method of
  reprocessing memories of distressing events by recounting them while using a form of dual
  attention stimulation such as eye movements, bilateral sound, or bilateral tactile stimulation (its
  use is controversial because of limited evidence)

Complications
• substance abuse, relationship difficulties, depression, impaired social and occupational
  functioning disorders, Axis II disorders
Adjustment Disorder

DSM-IV-TR Diagnostic Criteria for Adjustment Disorder

A. the development of emotional or behavioural symptoms in response to an identifiable stressor(s) occurring within 3 mo of the onset of the stressor(s)

B. these symptoms or behaviours are clinically significant as evidenced by either of the following
   (1) marked distress that is in excess of what would be expected from exposure to the stressor
   (2) significant impairment in social or occupational (academic) functioning

C. the stress-related disturbance does not meet criteria for another Axis I disorder and is not merely an exacerbation of a pre-existing Axis I or Axis II disorder

D. the symptoms do not represent bereavement

E. once the stressor (or its consequences) has terminated, the symptoms do not persist for more than an additional 6 mo
   • specify if
     * acute: if the disturbance lasts less than 6 mo
     * chronic: if the disturbance lasts for 6 mo or longer

Adjustment disorders are coded based on the subtype, which is selected according to the predominant symptoms

Classification
• types of stressors
  ▪ single (e.g. termination of romantic relationship)
  ▪ multiple (e.g. marked business difficulties and marital problems)
  ▪ recurrent (e.g. seasonal business crises)
  ▪ continuous (e.g. living in a crime-ridden neighbourhood)
  ▪ developmental events (e.g. going to school, leaving parental home, getting married, becoming a parent, failing to attain occupational goals, retirement)
  ▪ Note: the specific stressor is specified on Axis IV

• subtypes, adjustment disorder with:
  ▪ depressed mood
  ▪ anxiety
  ▪ mixed anxiety and depressed mood
  ▪ disturbance of conduct
  ▪ mixed disturbance of emotions and conduct
  ▪ unspecified

Epidemiology
• M=F

Treatment
• brief psychotherapy (group, individual), crisis intervention
• biological
  ▪ benzodiazepines may be used for those with anxiety symptoms (short-term, low-dose, regular schedule)
  ▪ SSRIs for both depression and anxiety symptoms

Bereavement

Clinical Presentation
• length and characteristics of “normal” bereavement are variable between individuals/cultures
• may present with symptoms of MDE/MDD but individual regards depressed mood as normal
• diagnosis of MDD only given if symptoms persist >2 mo after loss (note – this stipulation has been removed in DSM-5; it is now possible to diagnose MDD regardless of how close it comes to loss)
• presence of following symptoms may indicate abnormal grief/presence of MDD
  ▪ guilt about things other than actions taken or not taken by the survivor at the time of death
  ▪ thoughts of death other than the survivor feeling that they would be better off dead or should have died with the deceased person; morbid preoccupation with worthlessness
  ▪ marked psychomotor retardation; prolonged and marked functional impairment
  ▪ hallucinatory experiences other than thinking that the survivor hears the voice of or transiently sees the image of the deceased person
• prolonged or complicated grief may occur if unable to “move on” or re-engage in life

Risk Factors for Poor Bereavement Outcome:
• Poor social supports
• Unanticipated death or lack of preparation for death
• Highly dependent relationship with deceased
• High initial distress
• Other concurrent stresses and losses
• Death of a child
• Pre-existing psychiatric disorders, especially depression and separation anxiety
Delirium

- see Neurology, N17 and Geriatric Medicine, GM3

DSM-IV-TR Diagnostic Criteria for Delirium due to a GMC

A. disturbance of consciousness (i.e. reduced clarity of awareness of the environment) with reduced ability to focus, sustain, or shift attention
B. a change in cognition (such as memory deficit, disorientation, language disturbance) or the development of a perceptual disturbance that is not better accounted for by a pre-existing, established, or evolving dementia
C. the disturbance develops over a short period of time (usually hours to days) and tends to fluctuate during the course of the day
D. there is evidence from the history, physical examination, or laboratory findings that the disturbance is caused by the direct physiological consequences of a GMC

Clinical Presentation and Assessment

- common symptoms
  - wandering attention
  - distractibility
  - disorientation (time, place, rarely person)
  - misinterpretations, illusions, hallucinations
  - speech/language disturbances (dysarthria, dysnomia, dysgraphia)
  - affective symptoms (anxiety, fear, depression, irritability, anger, euphoria, apathy)
  - shifts in psychomotor activity (gropping/picking at clothes, attempts to get out of bed when unsafe, sudden movements, sluggishness, lethargy)
- Folstein Mini Mental Status Exam (see sidebar, PS3) is helpful to assess baseline of altered mental state (i.e. score will improve as symptoms resolve)

Risk Factors

- hospitalization (incidence 10-40%)
- nursing home residents (incidence 60%)
- childhood (e.g. febrile illness, anticholinergic use)
- old age (especially males)
- severe illness (e.g. cancer, AIDS)
- pre-existing cognitive impairment or brain pathology
- recent anesthesia
- substance abuse

Etiology

- Infectious (encephalitis, meningitis, UTI, pneumonia)
- Withdrawal (alcohol, barbiturates, benzodiazepines)
- Acute metabolic disorder (electrolyte imbalance, hepatic or renal failure)
- Trauma (head injury, postoperative)
- CNS pathology (stroke, hemorrhage, tumour, seizure disorder, Parkinson's)
- Hypoxia (anemia, cardiac failure, pulmonary embolus)
- Deficiencies (vitamin B₁₂, folic acid, thiamine)
- Endocrinopathies (thyroid, glucose, parathyroid, adrenal)
- Acute vascular (shock, vasculitis, hypertensive encephalopathy)
- Toxins: substance use, sedatives, opioids (especially morphine), anesthetics, anticholinergics, anticonvulsants, dopaminergic agents, steroids, insulin, glyburide, antibiotics (especially quinolones), NSAIDs
- Heavy metals (arsenic, lead, mercury)

Investigations

- standard: CBC and differential, electrolytes, Ca²⁺, PO₄³⁻, Mg²⁺, glucose, ESR, LFTs, Cr, BUN, TSH, vitamin B₁₂, folic acid, albumin, urine C&S, R&M
- as indicated: ECG, CXR, CT head, toxicology/heavy metal screen, VDRH, HIV, LP, EEG (typically abnormal: generalized slowing or fast activity), blood cultures
- indications for CT head: focal neurological deficit, acute change in status, anticoagulant use, acute incontinence, gait abnormality, history of cancer
Management

• intrinsic
  - identify and treat underlying cause immediately
  - stop all non-essential medications
  - maintain nutrition, hydration, electrolyte balance and monitor vitals

• extrinsic
  - environment should be quiet and well lit
  - optimize hearing and vision
  - room near nursing station for closer observation; constant care if patient jumping out of bed, pulling out lines
  - family member present for reassurance and re-orientation
  - calendar, clock for orientation cues

• biological
  - low dose antipsychotics
  - haloperidol has the most evidence; reasonable alternatives include risperidone, olanzapine or quetiapine
  - benzodiazepines only to be used in alcohol withdrawal delirium; otherwise, can worsen delirium

• physical restraints if patient becomes violent

Prognosis

• up to 50% 1 yr mortality rate after episode of delirium

Dementia

• see Neurology, N17

DSM-IV-TR Diagnostic Criteria for Dementia (Alzheimer’s Type)

A. the development of multiple cognitive deficits manifested by both
  1. memory impairment (impaired ability to learn new information or to recall previously learned information)
  2. ≥1 of the following cognitive disturbances:
     * aphasia (language disturbance)
     * apraxia (impaired ability to carry out motor activities despite intact motor function)
     * agnosia (failure to recognize or identify objects despite intact sensory function)
  3. disturbance in executive functioning (i.e. planning, organizing, sequencing, abstracting)
B. the cognitive deficits in Criteria A1 and A2 each cause significant impairment in social or occupational functioning and represent a significant decline from a previous level of functioning
C. the course is characterized by gradual onset and continuing cognitive decline
D. the cognitive deficits in Criteria A1 and A2 are not due to any of the following:
  1. other central nervous system conditions that cause progressive deficits in memory and cognition
  2. systemic conditions that are known to cause dementia
  3. substance-induced conditions
E. the deficits do not occur exclusively during the course of a delirium
F. the disturbance is not better accounted for by another Axis I disorder

Epidemiology

• prevalence increases with age: 10% in patients >65 yr of age; 25% in patients over 85 yr of age
• prevalence is increased in people with Down’s syndrome and head trauma
• Alzheimer’s dementia comprises >50% of cases; vascular causes comprise approximately 15% of cases (other causes of dementia – see Neurology, N18)
• average duration of illness from onset of symptoms to death is 8-10 yr

Subtypes

• with or without behavioural disturbance (e.g. wandering, agitation)
• early onset: age of onset <65 yr
• late onset: age of onset >65 yr

Investigations (rule out reversible causes)

• standard: see Delirium, PS19
• as indicated: VDRL, HIV, SPECT, CT head in dementia
• indications for CT head: same as for delirium, plus: age <60, rapid onset (unexplained decline in cognition or function over 1-2 mo), dementia of relatively short duration (<2 yr), recent significant head trauma, unexplained neurological symptoms (new onset of severe headache/seizures)
Management

- see Neurology, N20 for further management
- treat underlying medical problems and prevent others
- provide orientation cues for patient (e.g. clock, calendar)
- provide education and support for patient and family (e.g. day programs, respite care, support groups, home care)
- consider long-term care plan (nursing home) and power of attorney/living will
- inform Ministry of Transportation about patient’s inability to drive safely
- consider pharmacological therapy
  - cholinesterase inhibitors [e.g. donepezil (Aricept®)] for mild to severe disease
  - NMDA receptor antagonist (e.g. memantine) for moderate to severe disease
  - low-dose neuroleptics (e.g. risperidone, quetiapine), antidepressants or trazodone if behavioural or emotional symptoms prominent – start low and go slow
- reassess pharmacological therapy every 3 mo

Substance-Related Disorders

Epidemiology

- 47% of those with substance abuse have mental health problems
- 29% of those with a mental health disorder have a substance use disorder
- 47% of those with schizophrenia and 25% of those with an anxiety disorder have a substance use disorder

Types of Substance Use Disorders

1. *Substance abuse*: maladaptive pattern of substance use leading to clinically significant impairment or distress, as manifested by ≥1 of the following occurring within a 12 mo period
   - recurrent use in situations in which it is physically hazardous (e.g. driving)
   - recurrent use resulting in failure to fulfill major role obligation
   - recurrent substance-related legal problems
   - continued use despite interference with social or interpersonal function

Substance Abuse

HELP
- Hazardous
- Education/work/home consequences
- Legal problems
- Personal/social consequences
2. **substance dependence**: maladaptive pattern of substance use leading to clinically significant impairment or distress as manifested by ≥3 occurring at any time in the same 12 mo period

- tolerance (need for increased amount to achieve intoxication or diminished effect with same amount of substance)
- withdrawal/usage to avoid withdrawal
- taken in larger amount or over longer period than intended
- persistent desire or unsuccessful efforts to cut down
- excessive time to procure, use substance, or recover from its effects
- important interests/activities given up or reduced
- continued use despite physical/psychological problem caused/exacerbated by substance

**Note**: in DSM-5 "Substance Use Disorders" will take the place of distinguishing substance abuse from substance dependence

### Classification of Substances

</tr>
</tbody>
</table>

### Nicotine

- see [Family Medicine, Smoking Cessation, FM10](#)

### Alcohol

- see [Family Medicine, Alcohol, FM12](#) and [Emergency Medicine, ER48](#)

#### History

- CAGE: validated screening questionnaire
  - C ever felt the need to Cut down on drinking?
  - A ever felt Annoyed at criticism of your drinking?
  - G ever feel Guilty about your drinking?
  - E ever need a drink first thing in morning (Eye opener)?
  - for men, a score of ≥2 is a positive screen; for women, a score of ≥1 is a positive screen
  - if positive CAGE, then assess further to distinguish between problem drinking and alcohol dependence

#### General Assessment

- When was your last drink?
- Do you have to drink more to get the same effect?
- Do you get shaky or nauseous when you stop drinking?
- Have you ever had a withdrawal seizure?
- How much time and effort do you put into obtaining alcohol?
- Has your drinking affected your ability to work, go to school, or have relationships?
- Have you suffered any legal consequences?
- Has your drinking caused any medical problems?

#### Table 5. Canada’s Low-Risk Alcohol Drinking Guidelines

<table>
<thead>
<tr>
<th>Moderate Drinking</th>
<th>Men: 3 or less/d (&lt;15/wk)</th>
<th>Women: 2 or less/d (&lt;10/wk)</th>
<th>Elderly: 1 or less/d</th>
</tr>
</thead>
</table>

#### Alcohol Intoxication

- legal limit for impaired driving is 10.6 mmol/L (50 mg/dL) reached by 2-3 drinks/h for men and 1-2 drinks/h for women
- coma can occur with >60 mmol/L (non-tolerant drinkers) and 90-120 mmol/L (tolerant drinkers)

#### Alcohol Withdrawal

- occurs within 12 to 48 h after prolonged heavy drinking and can be life-threatening
- alcohol withdrawal can be described as having 4 stages, however not all stages may be experienced
  - stage 1 (onset 12-18 h after last drink): "the shakes" tremor, sweating, agitation, anorexia, cramps, diarrhea, sleep disturbance
  - stage 2 (onset 7-38 h): alcohol withdrawal seizures, usually tonic-clonic, nonfocal and brief
  - stage 3 (onset 48 h): visual, auditory, olfactory or tactile hallucinations
  - stage 4 (onset 3-5 d): delirium tremens, confusion, delusions, hallucinations, agitation, tremors, autonomic hyperactivity (fever, tachycardia, hypertension)

- course: in young almost completely reversible; elderly often left with cognitive deficits
- mortality rate 20% if untreated

- **MCAT**
  - More drug needed to achieve intoxication
  - Cutting down unsuccessful
  - Activities given up or reduced
  - Time to procure, use substance, or recover from effects is excessive

- **A “Standard Drink”**
  - Spirit (40%): 1.5 oz. or 43 mL
  - Table Wine (12%): 5 oz. or 142 mL
  - Fortified Wine (18%): 3 oz. or 85 mL
  - Regular Beer (5%): 12 oz. or 341 mL
  - OR
  - 1 pint of beer = 1.5 SD
  - 1 bottle of wine = 5 SD
  - 1 “mickey” = 8 SD
  - “26-er” = 17 SD
  - “40 oz.” = 27 SD

- **Delirium Tremens**
  - (alcohol withdrawal delirium)
  - Autonomic hyperactivity (diaphoresis, tachycardia, increased respiration)
  - Hand tremor
  - Insomnia
  - Psychomotor agitation
  - Anxiety
  - Nausea or vomiting
  - Tonic-clonic seizures
  - Visual/tactile/auditory hallucinations
  - Persecutory delusions

- Make sure to ask about other alcohols: mouthwash, rubbing alcohol, methanol, ethylene glycol, aftershave (may be used as a cheaper alternative)
Management of Alcohol Withdrawal

- monitor using the Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) scoring system
  - areas of assessment include
    - nausea and vomiting
    - tactile disturbances
    - tremor
    - auditory disturbances
    - agitation
    - all categories are scored from 0-7 (except: orientation/sensorium 0-4), maximum score of 67
    - mild <10
    - moderate 10-20
    - severe >20

Table 6. CIWA-A Scale Treatment Protocol for Alcohol Withdrawal

| Basic Protocol | Diazepam 20 mg PO q1-2h prn until CIWA-A < 10 points |
| History of Withdrawal Seizures | Dexamphetamine 20 mg PO q1h for minimum of three doses regardless of subsequent CIWA scores |
| If age > 65 or patient has severe liver disease, severe asthma or respiratory failure | Lorazepam PO/SI/IM 1-4 mg q1-2h |
| If hallucinations are present | Haloperidol 2-5 mg IM/PO q1-4h – max 5 doses/d or atypical antipsychotics (olanzapine, risperidone) Diazepam 20 mg x 3 doses as seizure prophylaxis (haloperidol lowers seizure threshold) |
| Admit to Hospital if | Still in withdrawal after > 80 mg of diazepam Delirium tremens, recurrent arrhythmias, or multiple seizures Medically ill or unsafe to discharge home |

Wernicke-Korsakoff Syndrome

- alcohol-induced amnestic disorders due to thiamine deficiency
- necrotic lesions: mammillary bodies, thalamus, brainstem
- Wernicke’s encephalopathy (acute and reversible): triad of nystagmus (CN VI palsy), ataxia and confusion
- Korsakoff’s syndrome (chronic and only 20% reversible with treatment): anterograde amnesia and confabulations; cannot occur during an acute delirium or dementia and must persist beyond usual duration of intoxication/withdrawal
- management
  - Wernicke’s: thiamine 100 mg PO OD x 1-2 wk
  - Korsakoff’s: thiamine 100 mg PO bid/tid x 3-12 mo

Treatment of Alcohol Dependence

- non-pharmacological
  - psychotherapy: motivational enhancement therapy (MET, increasing motivation to change), CBT (assertiveness training, increasing social support, planning leisure activities), marital and family therapy
  - behaviour therapy: contingency management, community reinforcement approach (CRA)
  - supportive services: counseling, detoxification centres, Alcoholics Anonymous
  - inpatient programs (e.g. 28-day programs)
    - individual readiness for change must always be considered with non-pharmacological interventions (refer to Prochaska’s Stages of Change Model, Population Health and Epidemiology, PH6)

- pharmacological
  - naltrexone: opioid antagonist, shown to be successful in reducing the “high” associated with alcohol, moderately effective in reducing cravings, frequency or intensity of alcohol binges
  - disulfiram (Antabuse®): blocks oxidation of alcohol (blocks acetaldehyde dehydrogenase);
    - with alcohol consumption, acetaldehyde accumulates to cause a toxic reaction (vomiting, tachycardia, death); if patient relapses, must wait 48 h before restarting Antabuse®
  - acamprosate (Campral): NMDA glutamate receptor antagonist; useful in maintaining abstinence and decreasing cravings

Opioids

- types of opioids: heroin, morphine, oxycodone, Tylenol #3® (codeine), hydromorphone
- major risks associated with the use of contaminated needles: increased risk of hepatitis B and C, bacterial endocarditis, HIV/AIDS

Acute Intoxication

- direct effect on receptors in CNS resulting in decreased pain perception, sedation, decreased sex drive, nausea/vomiting, decreased GI motility (constipation and anorexia), and respiratory depression
Toxic Reaction
- typical syndrome includes shallow respirations, miosis, bradycardia, hypothermia, decreased level of consciousness
- management
  - ABGs
  - IV glucose
  - naloxone hydrochloride (Narcan®): 0.4 mg up to 2 mg IV for diagnosis
  - treatment: intubation and mechanical ventilation, ± naloxone drip, until patient alert without naloxone (up to 48+ h with long-acting opioids)
  - caution with longer half-life; may need to observe for toxic reaction for at least 24 h

Withdrawal
- symptoms: depression, insomnia, drug-craving, myalgias, nausea, chills, autonomic instability (lacrimation, rhinorrhea, piloerection)
- onset: 6-12 h; duration: 5-10 d
- complications: loss of tolerance (overdose on relapse), miscarriage, premature labour
- management: long-acting oral opioids (methadone, buprenorphine), α-adrenergic agonists (clonidine)

Treatment of Chronic Abuse
- psychosocial treatment (e.g. Narcotics Anonymous) usually emphasize total abstinence
- naltrexone or naloxone (opioid antagonists) may also be used to extinguish drug-seeking behaviour
- long-term treatment may include withdrawal maintenance treatment with methadone or buprenorphine

Suboxone® formulation includes naloxone in addition to buprenorphine, in an effort to prevent injection of the drug. When naloxone is injected, it will precipitate opiate withdrawl and block the opiate effect of buprenorphine; however it will not have this antagonist action when taken sublingually.

Table 7. Comparison of Methadone and Suboxone® (buprenorphine and naloxone)

<table>
<thead>
<tr>
<th></th>
<th>Suboxone®</th>
<th>Methadone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mechanism of action</td>
<td>Combined formulation of partial opiate agonist and opiate antagonist (which is only active when injected)</td>
<td>Full opiate agonist</td>

Cocaine
- street names: blow, C, coke, crack, flake, freebase, rock, snow
- alkaloid extracted from leaves of the coca plant; blocks presynaptic uptake of dopamine (causing euphoria), norepinephrine and epinephrine (causing vasospasm, hypertension)
- self-administered by inhalation or intravenous route

Intoxication
- elation, euphoria, pressured speech, restlessness, sympathetic stimulation (e.g. tachycardia, mydriasis, sweating)
- prolonged use may result in paranoia and psychosis

Overdose
- medical emergency: hypertension, tachycardia, tonic-clonic seizures, dyspnea, and ventricular arrhythmias
- treatment with IV diazepam to control seizures and propranolol or labetalol to manage hypertension and arrhythmias

Withdrawal
- initial "crash" (1-48 h): increased sleep, increased appetite
- withdrawal (1-10 wk): dysphoric mood plus fatigue, irritability, vivid unpleasant dreams, insomnia or hypersomnia, psychomotor agitation or retardation
- complications: relapse, suicide (significant increase in suicide during withdrawal period)
- management: supportive management

OxyNEO vs. OxyContin
As of 2012, OxyContin was no longer available in Canada and was replaced by a new formulation of oxycodone called OxyNEO. OxyNEO is reported to be more tamper-resistant than OxyContin as the tablet is more difficult to crush. Furthermore, if OxyNEO is crushed, and added to water, it forms a thick gel-like substance that cannot be easily injected.

</tbody>
</table>
**Treatment of Chronic Abuse**
- psychotherapy, group therapy, NA (narcotics anonymous) and behaviour modification useful in maintaining abstinence

**Complications**
- cardiovascular: arrhythmias, MI, CVA, ruptured AAA
- neurologic: seizures
- psychiatric: psychosis, paranoia, delirium, suicidal ideation

**Amphetamines**
- intoxication characterized by euphoria, improved concentration, sympathetic and behavioural hyperactivity and at high doses can cause coma
- chronic use can produce a paranoid psychosis which can resemble schizophrenia with agitation, paranoia, delusions and hallucinations
- withdrawal symptoms include dysphoria, fatigue, and restlessness
- treatment of stimulant psychosis: antipsychotics

**Cannabis**
- cannabis (marijuana) is the most commonly used illicit drug
- psychoactive substance: delta-9-tetrahydrocannabinol (A9-THC)
- intoxication characterized by tachycardia, conjunctival vascular engorgement, dry mouth, altered sensorium, increased appetite, increased sense of well-being, euphoria/laffughter, muscle relaxation, impaired performance on psychomotor tasks including driving
- high doses can cause depersonalization, paranoia, anxiety and may trigger psychosis and schizophrenia if predisposed
- chronic use associated with tolerance and an apathetic, amotivational state
- cessation does produce a significant withdrawal phenomenon
- treatment of dependence: behavioural and psychological interventions to maintain an abstinent state

**Hallucinogens**
- types of hallucinogens: LSD, mescaline, psilocybin mushrooms, PCP, salvia
- LSD is a highly potent drug: intoxication characterized by tachycardia, HTN, mydriasis, tremor, hyperpyrexia, and a variety of perceptual and mood changes
- high doses can cause depersonalization, paranoia, and anxiety
- no specific withdrawal syndrome characterized
- treatment of agitation and psychosis: support, reassurance, diminished stimulation; benzodiazepines or high potency antipsychotics seldom required

**“Club Drugs”**

<table>
<thead>
<tr>
<th>Drug</th>
<th>Mechanism</th>
<th>Effect</th>
<th>Adverse Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDMA (Ecstasy, “X”, “E”)</td>
<td>Acts on serotonergic and dopaminergic pathways, properties of a hallucinogen and stimulant</td>
<td>Enhanced sensorium; feelings of well-being, empathy</td>
<td>Sweating, tachycardia fatigue, muscle spasms (especially jaw clenching), ataxia, hyperthermia, arrhythmias, DIC, rhabdomyolysis, renal failure, seizures, death</td>
</tr>
<tr>
<td>Gamma Hydroxybutyrate (GHB, “G”, “Liquid Ecstasy”)</td>
<td>Biphasic dopamine response (inhibition then release) and releases opiate-like substance</td>
<td>Euphoric effects, increased aggression, impaired judgment</td>
<td>Sweating, tachycardia, fatigue, muscle spasms (especially jaw clenching), ataxia, severe withdrawal from abrupt cessation of high doses: tremor, seizures, psychosis</td>
</tr>
<tr>
<td>Flunitrazepam (Rohypnol®, “Roofies”, “Rope”, “The Forget Pill”)</td>
<td>Potent benzodiazepine, rapid oral absorption</td>
<td>Sedation, psychomotor impairment, amnesic effects, decreased sexual inhibition</td>
<td>CNS depression with E0DH</td>
</tr>
<tr>
<td>Ketamine (Special K, “K-Kat”)</td>
<td>NMDA receptor antagonist, rapid-acting general anesthetic used in pediatrics and by veterinarians</td>
<td>“Dissociative” state, profound amnesia/analgesia; hallucinations and sympathomimetic effects</td>
<td>Psychological distress, accidents due to intensity of experience and lack of bodily control, in overdose, decreased LOC, respiratory depression, catatonia</td>
</tr>
</tbody>
</table>

**Medical Uses of Marijuana**
- Anorexia-cachexia (AIDS, cancer)
- Spasticity, muscle spasms (multiple sclerosis, spinal cord injury)
- Levodopa-induced dyskinesia (Parkinson’s Disease)
- Controlling tics and obsessive-compulsive behaviour (Tourette’s syndrome)
- Reducing intra-ocular pressure (glaucoma)

**Cannabis Use and Risk of Psychotic or Affective Mental Health Outcomes: A Systematic Review**

**Date Rape Drugs**
- GHB
- Flunitrazepam (Rohypnol®)
- Ketamine

**Formication**
Tactile hallucination that insects or snakes are crawling over or under the skin. Especially associated with crystal meth use.

**Pharm Party**
An increasing trend among teenagers where assorted prescription medications are brought to a party and ingested at random.
Table 8. The Mechanism and Effects of Common “Club Drugs” (continued)

<table>
<thead>
<tr>
<th>Drug</th>
<th>Mechanism</th>
<th>Effect</th>
<th>Adverse Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methamphetamine</td>
<td>Amphetamine stimulant, induces norepinephrine, dopamine and serotonin release</td>
<td>Rush begins in min, effects last 6-8 h, increased activity, decreased appetite, general sense of well-being, tolerance occurs quickly, users often binge and crash</td>
<td>Short term use: high agitation, rage, violent behaviour, occasionally hyperthermia and convulsions Long term use: addiction, anxiety, confusion, insomnia, paranoia, auditory and tactile hallucinations (esp. formication), delusions, mood disturbance, suicidal and homicidal thoughts, stroke, may be contaminated with lead, and IV users may present with acute lead poisoning</td>
</tr>
<tr>
<td>Phencyclidine</td>
<td>Not understood, used by veterinarians to immobilize large animals</td>
<td>Amnestic, euphoric, hallucinatory state</td>
<td>Horizontal/vertical nystagmus, myoclonus, ataxia, autonomic instability (treat with diazepam IV), prolonged agitated psychosis (treat with haloperidol); high risk for suicide; violence towards others High dose can cause coma</td>
</tr>
</tbody>
</table>

**Somatoform Disorders**

**General Characteristics**
- physical signs and symptoms lacking a known medical basis in the presence of psychological factors that are judged to be important in the initiation, exacerbation, or maintenance of the disturbance
- cause significant distress or impairment in functioning
- symptoms are produced unconsciously and are not the result of malingering or factitious disorder
- primary gain: somatic symptom represents a symbolic resolution of an unconscious psychological conflict; serves to reduce anxiety and conflict; no external incentive
- secondary gain: the sick role; external benefits obtained or unpleasant duties avoided (e.g. work)

**Management of Somatoform Disorders**
- brief frequent visits
- limit number of physicians involved in care
- focus on psychosocial not physical symptoms
- minimize medical investigations; coordinate necessary investigations
- psychotherapy: CBT, biofeedback, conflict resolution
- minimize psychotropic drugs: anxiolytics in short term only, antidepressants for depressive symptoms

**Body Dysmorphic Disorder**
- preoccupation with imagined defect in appearance or excess concern around a slight anomaly
- usually related to the face
- M=F; prevalence 1-2.2% in the community; 6-15% in dermatology/cosmetic surgery clinics
- may lead to avoidance of work or social situations

**Conversion Disorder**
- one or more symptoms or deficits affecting voluntary motor or sensory function that mimic a neurological or GMC (e.g. impaired co-ordination, local paralysis, double vision, seizures or convulsions)
- psychological factors thought to be etiologically related to the symptoms as the initiation of symptoms is preceded by conflicts or other stressors
- 11-300/100,000 in general population; focus of treatment in 1-3% of outpatient referrals to mental health clinics
- more common in rural populations and in individuals with little medical knowledge
- spontaneous remission in 95% of acute cases, 50% of chronic cases (>6 mo)
**Hypochondriasis**
- preoccupation with fear of having, or the idea that one has, a serious disease based on a misinterpretation of one or more bodily signs or symptoms
- evidence does not support diagnosis of a physical disorder
- fear of having a disease despite medical reassurance
- belief is not of delusional intensity (as in delusional disorder, somatic type) as person acknowledges unrealistic interpretation
- duration is ≥6 mo; onset in 3rd-4th decade of life
- community prevalence 1.1-4.5%; prevalence in general medical practice 4-9%; higher in psychiatric settings

**Pain Disorder**
- pain is primary symptom and is of sufficient severity to warrant medical attention
- usually no organic pathology but when it exists, reaction is excessive
- lifetime prevalence 12%
- psychiatric disorders (mood, anxiety, substance) may precede, co-exist or result from pain disorder

**Somatization Disorder**
- recurring, multiple, clinically significant physical complaints which result in patient seeking treatment or having impaired functioning
- ≥8 physical symptoms that have no organic pathology including each of:
  - four pain symptoms related to at least four different sites or functions
  - two gastrointestinal symptoms, not including pain
  - one sexual symptom, not including pain
  - one pseudo-neurological symptom, not including pain (e.g. numbness, paresthesia)
- onset before age 30; extends over a period of years
- lifetime prevalence 0.2-2% among women and 0.2% among men
- cultural factors may influence sex ratio
- complications: anxiety, depression, unnecessary medications or surgery
- often a misdiagnosis for an insidious illness so rule out all organic illnesses (e.g. multiple sclerosis)

**Dissociative Disorders**

**Definition**
- dissociation so severe that the usually integrated functions of consciousness and perception of self break down
- sudden or gradual onset, transient or chronic course
- symptoms cause distress or impaired functioning
- differential diagnosis: PTSD, acute stress disorder, somatization disorder, substance abuse, GMC (e.g. complex/partial seizures)

Table 9. Dissociative Disorders

<table>
<thead>
<tr>
<th>Amnesia</th>
<th>Fugue</th>
<th>Identity Disorder</th>
<th>Depersonalization Disorder</th>

</tbody>
</table>
**Sleep Disorders**

- see [Neurology, N42](#)

**Criteria for Diagnosis**

- causes significant distress or impairment in functioning
- not due to medications, drugs, or a GMC

---

**Nocturnal Myoclonus**

- middle-aged and elderly
- myoclonic jerks every 20-40 s
- bed partner complaints
- treatment: benzodiazepines (clonazepam, nitrazepam)

---

**Narcolepsy**

- see [Neurology, N42](#)

---

**Primary Insomnia**

- see [Family Medicine, FM48](#)

---

**Sleep Apnea**

- see [Respirology, R31](#)

---

**Sexuality and Gender**

---

**Gender Dysphoria**

- gender identity is set at approximately 3 yr of age

**typical presentation**

- strong and persistent cross-gender identification
- repeated stated desire or insistence that one is of the opposite sex
- preference for cross-dressing, cross-gender roles in make-believe play
- intense desire to participate in the stereotypical games and pastimes of the opposite sex
- strong preference for playmates of the opposite sex
- significant distress or impairment in functioning and persistent discomfort with his or her sex or gender role

**treatment**

- psychotherapy
- hormonal therapy
- sexual reassignment surgery

---

**Paraphilias**

- **definition**: recurrent, intense sexual arousal, fantasies, sexual urges or behaviour involving non-human objects, suffering or humiliation of oneself or one's partner, children or other non-consenting person causing significant distress or impairment in social, occupational or other areas of functioning

- **subtypes**: exhibitionism, fetishism, frotteurism, voyerism, pedophilia, sexual masochism, sexual sadism, transvestite fetishism, paraphilia NOS

- rarely self-referred; come to medical attention through interpersonal or legal conflict

- person usually has more than one paraphilia; 5% of paraphilias attributed to women

**typical presentation**

- begins in childhood or early adolescence; increasing in complexity and stability with age
- chronic, decreases with advancing age but may increase with stress

**treatment**

- anti-androgen drugs
- behaviour modification
- psychotherapy

---

**SEXUAL DYSFUNCTION**

- see [Gynecology, GY31](#) and [Urology, U30](#)
Eating Disorders

Epidemiology
- anorexia nervosa (AN): 1% of adolescent and young adult females; onset 13-20 yr old
- bulimia nervosa (BN): 2-4% of adolescent and young adult females; onset 16-18 yr old
- F:M=10:1; mortality 5-10%

Etiology
- multifactorial: psychological, sociological and biological associations
- individual: perfectionism, lack of control in other life areas, history of sexual abuse
- personality: obsessive-compulsive, histrionic, borderline
- familial: maintenance of equilibrium in dysfunctional family
- cultural factors: prevalent in industrialized societies, idealization of thinness in the media
- genetic factors
  - AN: 6% prevalence in siblings, with one study of twin pairs finding concordance in 9 of 12 monozygotic pairs versus concordance in 1 of 14 dizygotic pairs
  - BN: higher familial incidence of affective disorders than the general population

Risk Factors
- physical factors: obesity, chronic medical illness (e.g. diabetes mellitus)
- psychological factors: individuals who by career choice are expected to be thin, family history (mood disorders, eating disorders, substance abuse), history of sexual abuse, homosexual males, competitive athletes, concurrent associated mental illness [depression, OCD, anxiety disorder (especially panic and agoraphobia), substance abuse (specifically for BN)]

Anorexia Nervosa

DSM-IV-TR Diagnostic Criteria for Anorexia Nervosa

A. refusal to maintain body weight at or above a minimally normal weight for age and height (e.g. weight loss leading to maintenance of body weight less than 85% of that expected; or failure to make expected weight gain during period of growth, leading to body weight less than 85% of that expected)

B. intense fear of gaining weight or becoming fat, even though underweight

C. disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or denial of the seriousness of the current low body weight

D. in postmenarcheal females, amenorrhea, i.e. the absence of at least three consecutive menstrual cycles (note: this criterion has has been removed in DSM-5)

Specific Type
- restricting: during the current episode of AN, the person has not regularly engaged in binge-eating or purging behaviour
- binge-eating/purging: during the current episode of AN, the person has regularly engaged in binge-eating or purging behavior

Management
- outpatient programs and inpatient programs are available
- inpatient hospitalization for treatment of eating disorders is rarely on an acute basis (unless there is a concurrent psychiatric reason for emergent admission e.g. suicide risk)
- admit to a medical ward for hospitalization: <65% of standard body weight (<85% of standard body weight for adolescents), hypovolemia requiring intravenous fluid, heart rate <40 bpm, abnormal serum chemistry or if actively suicidal
- agree on target body weight on admission and reassure this weight will not be surpassed
- psychotherapy (individual/group/family): addressing food and body perception, coping mechanisms, health effects
- monitor for complications of AN (see Table 10)
- monitor for refeeding syndrome:
  - a potentially life-threatening metabolic response to refeeding in severely malnourished patients resulting in severe shifts in fluid and electrolyte levels
  - complications include hypophosphatemia, congestive heart failure, cardiac arrhythmias, delirium and death
  - prevention: slow refeeding, gradual increase in nutrition, supplemental phosphorus, close monitoring of electrolytes and cardiac status

Athletic Triad
- Disordered eating
- Amenorrhea
- Osteoporosis

Screening Question for Purging Behaviours
“To lose weight, some people will use laxatives or vomit, have you ever tried that or used other ways to lose weight?”

Some diabetics may use insulin to lose weight, be aware of this in Type 1 DM.
Prognosis
- early intervention much more effective
- with treatment, 70% resume a weight of at least 85% of expected levels and about 50% resume normal menstrual function
- eating peculiarities and associated psychiatric symptoms are common and persistent
- long-term mortality: 10% to 20% of patients hospitalized will die in next 10 to 30 yr (secondary to severe and chronic starvation, metabolic or cardiac catastrophes, with a significant proportion committing suicide)

Bulimia Nervosa

DSM-IV-TR Diagnostic Criteria for Bulimia Nervosa

A. recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following
   1. eating, in a discrete period of time, an amount of food that is larger than most people would eat during a similar period of time and under similar circumstances
   2. a sense of lack of control over eating during the episode (e.g. a feeling that one cannot stop eating or control what or how much one is eating)
B. recurrent inappropriate compensatory behaviour in order to prevent weight gain, such as self-induced vomiting, misuse of laxatives, diuretics, enemas, or other medications, fasting, or excessive exercise
C. the binge eating and inappropriate compensatory behaviours both occur, on average, at least twice a week for 3 mo
D. self-evaluation is unduly influenced by body shape and weight
E. the disturbance does not occur exclusively during episodes of AN

Specific Type
- purging: during the current episode of BN, the person has regularly engaged in self-induced vomiting or the misuse of laxatives, diuretics, or enemas
- non-purging: during the current episode of BM, the person has used other inappropriate compensatory behaviours, such as fasting or excessive exercise, but has not regularly engaged in purging behaviours

Associated Features
- fatigue and muscle weakness due to repetitive vomiting and fluid/electrolyte imbalance
- tooth decay
- swollen appearance around angle of jaw and puffiness of eye sockets due to fluid retention
- reddened knuckles, Russell’s sign (knuckle callus from self-induced vomiting)
- trouble concentrating
- weight fluctuation over time

Management
- admission for significant electrolyte abnormalities
- biological: treatment of starvation effects, SSRIs
- psychological: develop trusting relationship with therapist to explore personal etiology and triggers, CBT, family therapy, recognition of health risks
- social: challenge destructive societal views of women, use of hospital environment to provide external patterning for normative eating behaviour

Prognosis
- few recover without recurrence
- good prognostic factors: onset before age 15, achieving a healthy weight within 2 yr of treatment
- poor prognostic factors: later age of onset, previous hospitalizations, individual and familial disturbance

</tbody>
</table>

Personality Disorders

General Diagnostic Criteria
- an enduring pattern of inner experience and behaviour that deviates markedly from the expectations of the individual's culture; manifested in two or more of: cognition, affect, interpersonal functioning, impulse control
- inflexible and pervasive across a range of situations
- causes distress or impaired functioning not necessarily for the person with the personality disorder (PD), but for those around him/her
- pattern is stable and well established by adolescence or early adulthood
- associated with many complications, such as depression, suicide, violence, brief psychotic episodes, multiple drug use and treatment resistance
- each PD is present in 1% of the population and are lifelong and chronic
- the mainstay of treatment is psychotherapy with the addition of pharmacotherapy to treat associated axis I disorders (i.e. depression, anxiety, substance abuse)
- main treatment for borderline personality disorder is dialectical behavioural therapy (consists of validating rather than blaming the patient, and replacing maladaptive behaviour with adaptive behaviour)

Table 11. Classification and Diagnosis of Personality Disorders

Note: For each personality disorder, the most recognizable feature is indicated in italics.

Borderline Personality Disorder
- DESPAIRER
- Disturbance of identity
- Emotionally labile
- Suicidal behavior
- Paranoia or dissociation
- Abandonment (fear of)
- Impulsive
- Relationships unstable
- Emptiness (feelings of)
- Rage (inappropriate)

Antisocial Personality Disorder
- CORRUPT
- Cannot conform to law
- Obligations ignored
- Reckless disregard for safety
- Remorselessness
- Underhanded (deceitful)
- Planning insufficient (impulsive)
- Temper (irritable and aggressive)

</tbody>
</table>

The Child Psychiatric Interview

- **ID**
  - name, age, school grade, living situation, family situation (all family members, age and occupation of parents), demographics
- **Chief Complaint**
  - onset, time course, stressors, impact on child's and family's functioning, supports
  - child's functioning and behaviour at home, at school, and with peers
  - mental status (see MSE, PS3)
- **History of Present Illness**
  - symptoms and features of most likely diagnostic area [e.g. disruptive behaviour disorders (ADHD, CD, ODD), developmental disorders, learning disorders, abuse, mood disorders, and anxiety disorders]
  - in adolescents, consider psychotic disorders, eating disorders, and substance abuse disorders
  - screen for comorbid conditions
  - what was the child like before and after the symptoms? what has changed? what is happening now?
- **Additional History**
  - past history: pregnancy, neonatal, developmental, temperamental, medical, surgical
  - psych history: past assessments (e.g. psychiatric, psychological, educational), treatments
  - family history: similar symptoms, medical, developmental, and psychosocial issues
- **Risk Assessment**
  - physical/sexual abuse, suicidality, aggression/homicidality, firesetting, risky behaviour
  - past risk issues (past suicide attempts, past aggression), previous contact with child protection services
  - brief developmental history: pregnancy, birth, milestones, general behaviour, parents' method of discipline, school functioning, peer relationships

Developmental Concepts

- **temperament**: innate psycho-physiological and behavioural characteristics of a child (e.g. emotionality, activity, and sociability); spectrum from "difficult" to "slow-to-warm-up" to "easy temperament", plotted on nine parameters:
  - activity level, adaptation, attention span and persistence, distractibility, intensity of reaction, quality of mood, response to a new stimulus, rhythmicity, threshold of responsiveness
- **parental fit**: the congruence between parenting style (authoritative, authoritarian, permissive) and child's temperament
- **attachment**: special relationship between child and primary caretaker(s); develops during first year, best predictor of a child's attachment style is their parent's attachment style (see Table 13)
- **stranger anxiety** (8 mo): infants cry at approach of stranger
- **separation anxiety** (10-18 mo): separation from attachment figure results in distress

Table 13. Attachment Models

<table>
<thead>
<tr>

</tbody>
</table>
Mood Disorders

MAJOR DEPRESSIVE DISORDER (MDD)

Epidemiology
- pre-pubertal 1-2% (no gender differences); post-pubertal 4-18% (F:M = 2:1)

Clinical Presentation
- see Adult Mood Disorders, PS9
- physical factors: insomnia (children), hypersomnia (adolescents), somatic complaints, substance abuse
- psychological factors: irritability, boredom, anhedonia, low self-esteem, deterioration in academic performance, social withdrawal, lack of motivation
- comorbid diagnoses of anxiety, ADHD, conduct disorder, and eating disorders

Treatment
- majority never seek treatment
- individual (CBT, IPT)/family therapy and education, modified school program
- SSRIs (strongest evidence for fluoxetine)
- ECT: only in adolescents
- light therapy, self-help books

Prognosis
- prolonged episodes, up to 1-2 yr
- adolescent onset predicts chronic mood disorder; up to 2/3 will have another depressive episode within 5 yr
- complications
  - negative impact on family and peer relationships
  - school failure
  - significantly increased risk of suicide attempt (10%) or completion
  - substance abuse

BIPOLAR DISORDER

Clinical Presentation
- see Adult Bipolar Disorder/Mania, PS12
- mixed presentation and and psychotic symptoms (hallucinations and delusions) more common in adolescent population than adult population
- unipolar depression may be an early sign of adult bipolar disorder
  - ~30% of psychotic depressed adolescents receive a bipolar diagnosis within 2 yr of presentation
  - associated with rapid onset of depression, psychomotor retardation, mood-congruent psychosis, affective illness in family, pharmacologically induced mania

Treatment
- 1st line: mood stabilizers and/or antipsychotics
- 2nd line: antidepressants, benzodiazepines (careful of disinhibiting effect)

Anxiety Disorders

- prevalence 2-15%; F:M = 2:1

Diagnosis
- school problems, recurrent physical symptoms (abdominal pain, headaches) especially in mornings, social and relationship problems, social withdrawal and isolation, family conflict, irritability and mood symptoms, alcohol and drug use in adolescent

Treatment
- family psychotherapy, predictive and supportive environment
- CBT: child and parental education, relaxation techniques (e.g. deep breathing), exposure/desensitization, recognizing and correcting anxious thoughts
- pharmacotherapy: SSRIs (e.g. fluoxetine), benzodiazepines (e.g. clonazepam – use with caution, may have disinhibiting effect)
  - fluvoxamine and sertraline also have good evidence, particularly for OCD

Fluoxetine, Cognitive-Behavioral Therapy and Their Combination for Adolescents with Depression: Treatment for Adolescents with Depression Study (TADS) Randomized Controlled Trial

JAMA 2004;292:807-820

Study: Randomized controlled trial at 13 US academic and community clinics between spring 2000-summer 2003.

Patients: 439 patients ages 12-17 with a primary DSM IV diagnosis of major depressive disorder.

Outcomes: Children’s Depression Rating Scale-Revised (CDRS-R) total score.

Interventions: 12 wk of (1) fluoxetine (10-40 mg/d), (2) CBT, (3) CBT + fluoxetine (10-40 mg/d), or (4) placebo.

Results: Fluoxetine with CBT had a statistically significant CDRS-R score as compared to placebo (P<0.001) with a 71% response rate. This combo was greater than fluoxetine alone (P<0.02), and CBT alone (P<0.01). Fluoxetine alone was greater than CBT alone (P<0.01).
SEPARATION ANXIETY DISORDER

Epidemiology
- prevalence: 4% of children/adolescents
- on average 7.5 yr old at onset, 10 yr old at presentation
- common for mother to have an anxiety or depressive disorder

Differential Diagnosis
- simple or social phobia, depression, learning disorder, truancy, conduct disorder, school-related problems (e.g. bullying)

Clinical Presentation
- excessive and developmentally inappropriate anxiety on separation from primary caregiver with physical or emotional distress for at least 4 wk
- school refusal (75%)
- persistent worry, refusal to sleep, clinging, nightmares, somatic symptoms
- comorbid major depression common (2/3)
- worry about something happening to parent or themselves if separated

Prognosis
- if inadequately treated early on, may present later in a more severe form
- may develop into panic disorder with/without agoraphobia

SOCIAL PHOBIA (SOCIAL ANXIETY DISORDER)
- must distinguish between shy child and child with social anxiety
  - diagnosis only if anxiety interferes significantly with daily routine, social life, academic functioning, or if markedly distressed
  - features: temper tantrums, freezing, clinging behaviour, mutism, excessively timid, stays on periphery, refuses to be involved in group play
  - must be capable of developing social relationships
  - must occur in settings with peers, not just adults
  - selective mutism:
    - does not speak in front of others; no problems speaking at home
    - must rule out language or communication problems
    - severe form of social anxiety

POST-TRAUMATIC STRESS DISORDER
- diagnostic criteria same as adults (see PTSD, PS17)
  - in children, reliving of the trauma may occur through repetitive play which simulates the event, nightmares of the trauma which may progress to generalized nightmares (e.g. monsters), psychosomatic symptoms, omen formation (belief that there were predictors of the trauma which can be avoided in the future to escape future trauma)
  - common examples include: sexual/physical abuse, witnessing family violence, natural disasters
  - can also be associated with onset of sexual activity

OBSESSIVE-COMPULSIVE DISORDER
- diagnostic criteria same as adults, except it is not necessary for child to recognize thoughts or actions as excessive or unreasonable (see OCD, PS16)
  - 0.3–1% of children/adolescents; tends to begin earlier in boys than girls
    - tend to engage in rituals at home rather than in front of others
    - associated with Tourette’s disorder, tics, and ADHD
    - small subset associated with Group A Strep infections; has prepubertal onset and neurologic symptoms

PANIC DISORDER
- diagnostic criteria same as adults (see Panic Disorder, PS14)
- genetic/parental modeling/identification hypothesized as cause
- often parent with panic or depressive disorder

GENERALIZED ANXIETY DISORDER
- diagnostic criteria same as adults (see GAD, PS15)
  - Note: Only 1 item is required in children for Criteria C
  - often redo tasks, show dissatisfaction with their work and tend to be perfectionistic
  - often require reassurance and support to take on new tasks

SPECIFIC PHOBIA
- common phobias in childhood include a fear of heights, small animals, doctors, dentists, darkness, loud noises, thunder and lightning

Newer Generation Antidepressants for Depressive Disorders in Children and Adolescents
Cochrane DB Syst Rev 2012:11:CD004851
Study: Meta-analysis of 19 trials containing 3335 participants (including RCTs, cross-over trials and cluster trials).
Population: Children and adolescents aged 6-18 yr with diagnosed depressive disorder.
Interventions: Antidepressants, placebo.
Main Outcome Measure: Depression severity score.
Results: Children treated with an antidepressant had lower depression severity score and higher rates of response/remission. Children on antidepressants were also found to be at increased risk (59%) of suicide-related outcome (RR 1.58; 95% CI 1.02 to 2.45).
Conclusions: In children and adolescents, antidepressants are effective at treating depression, yet may cause a higher chance of suicide-related outcomes.

The shy child is quiet and reluctant to participate but slowly ‘warms up’.
**Childhood Schizophrenia**

**Epidemiology**
- 1/2,000 in childhood; increases after puberty to adult rates (1%) in late adolescence
- diagnostic criteria same as in adults (see Schizophrenia, PS6)
- less elaborate delusions than adults and visual hallucinations are more common
- <6 yr old may present in similar fashion to autism prior to onset of core symptoms
- prognosis poor as cognitive, language, social and personality development are disrupted

**Treatment**
- psychotherapy, family education
- low dose antipsychotics for psychotic symptoms (e.g. hallucinations) and target behaviours (e.g. aggression, hyperactivity, impulsiveness)
- hospitalization or residential placement, if severe

**Pervasive Developmental Disorders**

- include autism, Asperger’s, childhood disintegrative disorder, Rett’s disorder, and PDD NOS
- M:F = 3-4:1 (except for Rett’s with female predominance)

**Differential Diagnosis**
- developmental disability, childhood schizophrenia, social phobia, OCD, communication disorder, non-verbal learning disorder, ADHD, abuse, hearing or visual impairment, seizure disorder, motor impairment

**Management**
- hearing test to rule out impairment
- psychological testing to assess intellectual functioning and learning
- chromosomal analysis to rule out abnormalities (e.g. trisomy 21, fragile X syndrome)
- rule out psychotic disorders, social problems, depression, anxiety, abuse

**Treatment**
- team-based: school, psychologist, occupational therapist, physiotherapist, speech and language therapy, audiology, pediatrics, psychiatry
- family education and support
- treat concomitant disorders such as tics, OCD, anxiety, depression, and seizure disorder
- behaviour management, school programming
- pharmacotherapy: atypical antipsychotics (for aggression, agitation, self-mutilation, tics), SSRIs (for anxiety, depression), stimulants (for associated inattention and hyperactivity)

**Prognosis**
- variable, but improves with early intervention
- better if IQ >60 and able to communicate

**Note:** DSM-V has resulted in significant changes to these diagnoses. Autism, Asperger’s disorder, childhood disintegrative disorder and PDD NOS will be subsumed by the diagnosis of autism spectrum disorder

**AUTISTIC DISORDER**
- prevalence 1/1,000
- abnormalities in three areas:
  - **social interaction:** impaired non-verbal behaviours (eye contact, facial expression, hand gestures); failure to develop appropriate peer relationships; lack of seeking to share enjoyment/interests; lack of social/emotional reciprocity
  - **communication:** delay or lack of development of spoken language; impaired ability to start or sustain conversation with others; stereotyped/repetitive or idiosyncratic use of language; lack of make-believe play
  - **restricted and repetitive behaviours, interests, and activities:** stereotyped or restricted patterns of interest with abnormal intensity or focus; inflexible adherence to specific, non-functional routines; stereotyped hand or body movements (e.g. rocking); preoccupation with parts of objects (e.g. spinning wheels on toy cars only)
- at least 6 features before 3 yr old (at least 2 from social interaction and 1 from other 2 categories)

**ASPERGER’S DISORDER**
- prevalence 3/1,000
- no early speech and language delay, no cognitive deficits (express normal curiosity in environment and develop age-appropriate learning skills, self-help and adaptive behaviours), normal to high intelligence
- at least 2 items from social interaction and 1 from repetitive behaviours categories of autistic disorder criteria

Disorganized speech and behaviour is associated with many childhood disorders which must be differentiated from schizophrenia (e.g. Communication Disorders, Pervasive Developmental Disorders, ADHD, Stereotypic Movement Disorders)

Asperger’s vs. Autism
Children with Asperger’s have no delay or abnormality in language or cognition. Autism must have age of onset by 3 years whereas Asperger’s may not be diagnosed until later in life.
CHILDHOOD DISINTEGRATIVE DISORDER (CDD)
- similar to autism, but there must be a period of at least 2 yr (and up to 10 yr) of normal development followed by regression in multiple areas of functioning
- associated with developmental disability
- rule out degenerative brain disease, schizophrenia, general medical conditions

RETT’S DISORDER
- X-linked dominant disorder, therefore predominantly in girls
- restriction of brain growth beginning in first year of life
- normal development between 6 mo to 4 yr, then regression (loss of purposeful hand movements, developmental disability, seizures, neurological, respiratory and motor deficits)

**Attention Deficit Hyperactivity Disorder**

- prevalence: 5-12% of school-aged children; M:F = 4:1, although girls may be under-diagnosed
- girls tend to have inattentive/distractible symptoms; boys have impulsive/hyperactive symptoms

**Etiology**
- genetic: dopamine candidate genes, catecholamine/neuroanatomical hypothesis
- cognitive: developmental disability, inhibitory control and other errors of executive function
- arousal: alterations in the sensory system filters

**Diagnosis**
- differential: learning disorders, hearing/visual defects, thyroid, atopic conditions, congenital problems (fetal alcohol syndrome, Fragile X), lead poisoning, history of head injury, traumatic life events (abuse)
- diagnosis (3 subtypes):
  - **Combined Type**: 6 or more symptoms of inattention and 6 or more symptoms of hyperactivity-impulsivity
  - **Predominantly Inattentive Type**: 6 or more symptoms of inattention
  - **Predominantly Hyperactive-Impulsive Type**: 6 or more symptoms of hyperactivity-impulsivity
- symptoms persist for >6 mo
- onset before age 7
- symptoms present in at least two settings (i.e. home, school, work)
- interferes with academic, family, and social functioning
- does not occur exclusively during the course of another psychiatric disorder

**Table 14. Core Symptoms of ADHD (DSM-IV)**

<table>
<thead>
<tr>
<th>Inattention</th>
<th>Hyperactivity</th>
<th>Impulsivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Careless mistakes</td>
<td>Fidgets, squirms in seat</td>
<td>Blurs out answers before questions completed</td>
</tr>
<tr>
<td>Cannot sustain attention in tasks or play</td>
<td>Leaves seat when expected to remain seated</td>
<td>Difficulty awaiting turn</td>
</tr>
<tr>
<td>Does not listen when spoken to directly</td>
<td>Runs and climbs excessively</td>
<td>Interrupts/intrudes on others</td>
</tr>
<tr>
<td>Fails to complete tasks</td>
<td>Cannot play quietly</td>
<td></td>

<td></td>
<td></td>
</tr>
<tr>
<td>Forgetful</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Features**
- average onset 3 yr old
- identification upon school entry
- rule out developmental delay, genetic syndromes, encephalopathies or toxins (alcohol, lead)
- risk of substance abuse, particularly cannabis and cocaine, depression, anxiety, academic failure, poor social skills, risk of comorbid CD and/or ODD, risk of adult ASPD
- associated with family history of ADHD, difficult temperamental characteristics
Treatment
- non-pharmacological: parent management, anger control strategies, positive reinforcement, social skills training, individual/family therapy, resource room, tutors, classroom intervention, exercise routines, extracurricular activities
- pharmacological
  - standard treatment:
    - stimulants: methylphenidates (Ritalin®, Concerta® (long-acting)), Biphetin®,
    - amphetamines: dextroampheta mine, mixed amphetamine salts (Adderall®), lisdexamfetamine (Vyvanse®)
    - SNRI: atomoxetine (Strattera®)
  - for comorbid symptoms: antidepressants, antipsychotics

Prognosis
- 65% continue into adulthood; secondary personality disorders and compensatory anxiety disorders are identifiable
- 70-80% continue into adolescence, but hyperactive symptoms usually abate

Oppositional Defiant Disorder
- prevalence: 2-16%

Diagnosis
- pattern of negativistic/hostile and defiant behaviour for ≥6 mo with ≥4 of:
  - loses temper, argues with adults, defies adult rules, deliberately annoys, blames others, touchy/easily annoyed, angry and resentful, spiteful or vindictive
  - behaviour causes significant impairment in social, academic or occupational functioning
  - behaviours do not occur exclusively during the course of a psychotic or mood disorder
  - criteria not met for conduct disorder (CD); if 18 yr or older, criteria not met for ASPD
  - features that typically differentiate ODD from transient developmental stage: onset <8 yr, chronic duration (≥6 mo), frequent intrusive behaviour
  - impact of ODD: poor school performance, few friends, strained parent/child relationships
  - may progress to CD

Treatment
- establish boundaries
- parent management training and psychoeducation
- individual/family therapy
- pharmacotherapy for comorbid disorders
- school/day care interventions to help with behaviour management

Conduct Disorder
- prevalence: 1.5-3.4% (M:F = 4-12:1)

Etiology
- parental/familial factors: parental psychopathology (e.g. ASPD, substance abuse), child rearing practices (e.g. child abuse, discipline), low socio-economic status (SES), family violence
- child factors: difficult temperament, ODD, learning problems, neurobiology

Diagnosis
- differential: ADHD, depression, head injury, substance abuse
- diagnostic: use multiple sources (Achenbach Child Behavioural Checklist, Teacher’s Report Form)
  - pattern of behaviour that violates rights of others and age appropriate social norms with ≥3 criteria noted in past 12 mo and ≥1 in past 6 mo:
    - aggression to people and animals (bullying, physical fights, use of weapons, forced sex)
    - destruction of property, firesetting with intent to damage
    - deceitfulness or theft (breaking and entering, car theft)
    - violation of rules (out all night before age 13, runaway ≥2 times or for long periods of time, often truant from school before age 13)
    - disturbance causes clinically significant impairment in social, academic or occupational functioning
    - if individual is 18 yr or older, criteria not met for ASPD

- diagnostic types
  - childhood onset: at least one criterion prior to age 10
  - adolescent onset: absence of any criteria until age 10
  - more aggressive, gang-related delinquency
  - mild, moderate, severe
Treatment
• early intervention necessary and more effective; long-term follow-up required
• parent management training, anger replacement training, CBT, family therapy, education/employment programs, social skills training, medications for aggressiveness or comorbid disorders
• pharmacotherapy is insufficient; mainly used for treatment of comorbid disorders

Prognosis
• poor prognostic indicators include early-age onset, high frequency and variety of behaviours, pervasiveness (i.e. in home, school, community), comorbid ADHD, early sexual activity, substance abuse
• 50% of CD children become adult ASPD

Psychosocial Treatment
• see Pediatrics:
  ▪ Child Abuse, Pediatrics P14
  ▪ Chronic Recurrent Abdominal Pain, Pediatrics P39
  ▪ Developmental Delay, Pediatrics P22
  ▪ Intellectual Disability, Pediatrics P23
  ▪ Learning Disability, Pediatrics P25
  ▪ Elimination Disorders, Pediatrics P9
  ▪ Sleep Disturbances, Pediatrics P12

Psychotherapy
• theory: one’s present outlook is shaped by one's past and unconscious psychological forces
• insight allows change in personality and behaviour
• conflict – three stages
  ▪ non-resolvable conflict
  ▪ attempt to repress
  ▪ return of conflict in disguised form (symptom or character trait)
• emphasis on early interaction with caregiver
• sources of information
  ▪ past and present experiences and relationships
  ▪ relationship with therapist
    ▪ transference: unconscious reenactment of early interpersonal patterns in relationship with therapist
    ▪ countertransference: therapist's transference to patient
    ▪ resistance: elements in the patient which oppose treatment
• techniques
  ▪ free association: patient says whatever comes to mind
  ▪ dream analysis
  ▪ Prochaska’s stages of change model is important for all conflict resolutions

Defense Mechanisms
• defense mechanisms are unconsciously activated by the patient in response to anxiety provoking events and feelings

<table>
<thead>
<tr>
<th>Table 15. Defense Mechanisms</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Level 1: Psychotic Defenses</strong></td>
</tr>
<tr>
<td>Common in psychosis; normally seen throughout childhood and in dreams</td>
</tr>
<tr>
<td>• Denial: replacing external reality with wishful fantasy</td>
</tr>
<tr>
<td>• Distortion: reshaping of reality to meet inner beliefs</td>
</tr>
<tr>
<td>• Projection: interpreting internal impulses as though they are outside oneself; in psychosis seen as frank delusion about reality (e.g. persecutory delusions)</td>
</tr>
<tr>
<td><strong>Level 2: Immature Defenses</strong></td>
</tr>
<tr>
<td>Common in personality disorders, severe depression. Normally seen throughout adolescence</td>
</tr>
<tr>
<td>• Acting out: express unconscious wish through impulsive action</td>
</tr>
<tr>
<td>• Blocking: of thinking, affect, or impulse</td>
</tr>
<tr>
<td>• Hypochondriasis: exaggeration of illness</td>
</tr>
<tr>
<td>• Introjection: internalizing qualities of an object (i.e. victim identifying with aggressor)</td>
</tr>
<tr>
<td>• Passive-aggressive behaviour</td>
</tr>
<tr>
<td>• Regression: returning to an earlier stage of development to avoid present stressors</td>
</tr>
<tr>
<td>• Somatization: unconscious expression of psychic pain/tension as physical symptoms</td>
</tr>
</tbody>

<td>planning for future discomfort</td>
</tr>
<tr>
<td><strong>Asceticism</strong></td>
<td>denying pleasurable effects of an experience</td>
</tr>
<tr>
<td><strong>Humour</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Suppression</strong></td>
<td>postpone attention to impulse or conflict</td>
</tr>
</tbody>
</table>

### Psychodynamic Therapy

- **psychoanalysis** (exploratory psychotherapy)
  - original therapy developed by Freud, goal is self-revelation and insight
  - the exploration of the meaning of early experiences and how they affect emotions and patterns of behaviour presently
  - time intensive (e.g. 4-5 times/wk for 3-7 yr)
  - for individuals who can tolerate ambiguity in explorations of feelings and treatment
- **supportive psychotherapy**
  - goal is not insight but reduction of anxiety
  - strengthen healthy defense mechanisms to assist day-to-day functioning
  - techniques include: enhancing self-esteem, clarification, confrontation, rationalization, reframing, encouragement, rehearsal/anticipation, de-catastrophizing, allowing “venting” of frustrations
- **short term/brief psychotherapy**
  - resolution of particular emotional problems, or acute crisis
  - number of sessions agreed on at outset (6-20)
- **interpersonal psychotherapy**
  - short-term treatment looking at relationship patterns and teaching coping mechanisms
  - focus on personal social roles and relationships to help deal with problems in current functioning

### Behaviour Therapy

- modification of internal or external events which precipitate or maintain emotional distress; useful in the treatment of anxiety disorders, substance abuse, paraphilias
- **systematic desensitization**: mastering anxiety-provoking situations by approaching them gradually and in a relaxed state that limits anxiety
- **flooding**: confronting feared stimulus for prolonged periods until it is no longer frightening
- **positive reinforcement**: strengthening behaviour and causing it to occur more frequently by rewarding it
- **negative reinforcement**: causing behaviour to occur more frequently by removing a noxious stimulus when desired behaviour occurs
- **extinction**: causing a behaviour to diminish by not rewarding it
- **punishment** (aversion therapy): causing a behaviour to diminish by applying a noxious stimulus

### Cognitive Therapy

- theory: moods/emotions are influenced by one's thoughts
- psychiatric disturbances are frequently caused by habitual errors in thinking
- goal is to help patient become aware of inaccurate automatic thoughts and correct assumptions with a more balanced perspective
- useful for depression, anxiety disorders, self-esteem problems
- use of this therapy presupposes a significant level of functioning of the patient
- patients asked to keep thought records (often in chart form, with column headings “situation”, “feeling”, “thought” and “cognitive distortion”) to monitor their thoughts, when/where they think these thoughts, how the thoughts make them feel and what their underlying error in thinking might be
Cognitive Behavioural Therapy (CBT)

- combines cognitive and behaviour therapies to teach the patient to weaken connections between thinking patterns, habitual behaviours and mood/anxiety problems
- good for treatment of mild/moderate depression/anxiety

Dialectical Behavioural Therapy (DBT)

- therapy that combines CBT techniques with approaches derived from Buddhist meditation practices
- originally developed for borderline patients but has since been found to be effective for the treatment of several other disorders
- focuses on four types of skills: mindfulness, emotion regulation, interpersonal effectiveness, and distress tolerance
- individual and group therapy settings

Other Therapies

- group psychotherapy
  - goals: self-understanding, acceptance, social skills
- family therapy
  - family system considered more influential than individual especially for children
  - focus on here and now, re-establishing parental authority, strengthening normal boundaries, and rearranging alliances
- hypnosis: mixed evidence for the treatment of pain, phobias, anxiety, and smoking cessation
- mindfulness-based cognitive therapy: derived from Buddhist meditative practices; aims to help people attend to thoughts, behaviours and emotions non-judgmentally and in the moment using guided breathing exercises

Pharmacotherapy

Antipsychotics

- “antipsychotics” and “neuroleptics” are terms used interchangeably
- indications: schizophrenia and other psychotic disorders, mood disorders with or without psychosis, violent behaviour, autism, Tourette’s, somatoform disorders, dementia, OCD
- onset: immediate calming effect and decrease in agitation; thought disorder responds in 2-4 wk
- rational use:
  - no reason to combine antipsychotics
  - choosing an antipsychotic:
    - all antipsychotics are equally effective, except for clozapine
    - atypical antipsychotics are as effective as typical or first generation antipsychotics but are thought to have better side effect profiles
    - choose a drug that the patient has responded to in the past or that was used successfully in a family member
  - route: PO, short-acting or long-acting depot IM injections, sublingual
  - duration: minimum 6 mo, usually for life

Long-Acting Preparations

- antipsychotics formulated in oil for IM injection (see Table 17)
- received on an outpatient basis
- indications: individuals with schizophrenia or other chronic psychosis who relapse because of non-adherence
- dosing: start at low dosages, and then titrate every 2 to 4 wk to maximize safety and minimize side effects
- should be exposed to oral form prior to first injection
- side effects: risk of EPS, parkinsonism, increased risk of neuroleptic malignant syndrome

Canadian Guidelines for the Treatment of Acute Psychosis in the Emergency Setting

- haloperidol 5 mg IM ± lorazepam 2 mg IM
- olanzapine 2.5-10 mg (PO, IM, quick dissolve)
- risperidone 2 mg (M-tab, liquid)

Effectiveness of Antipsychotic Drugs in Patients with Chronic Schizophrenia

- NEJM 2005;353:1209-23
- Study: Randomized, double-blind, active-control trial with median follow-up of 6 mo.
- Patients: 1432 patients with a diagnosis of schizophrenia (as per DSM-IV criteria) and able to take antipsychotic medications (as determined by study doctors). Mean age 41, 74% male, 26% female.
- Intervention: 1 to 4 capsules daily of olanzapine (20.1 mg), quetiapine (514.3 mg), risperidone (3.9 mg), perphenazine (20.8 mg), or ziprasidone (112.8 mg), with dosage at the discretion of the study doctor. Mean modal doses in parentheses.
- Main Outcome: Discontinuation of treatment for any cause
- Results: Olanzapine group had statistically significant lower rate of discontinuation for any cause (84%) compared to other antipsychotics (70-76%). Quetiapine was associated with a significantly higher rate of metabolic side effects.

Effectiveness of Antipsychotic Drugs in Patients with Chronic Schizophrenia

- NEJM 2005;353:1209-23
- Study: Randomized, double-blind, active-control trial with median follow-up of 6 mo.
- Patients: 1432 patients with a diagnosis of schizophrenia (as per DSM-IV criteria) and able to take antipsychotic medications (as determined by study doctors). Mean age 41, 74% male, 26% female.
- Intervention: 1 to 4 capsules daily of olanzapine (20.1 mg), quetiapine (514.3 mg), risperidone (3.9 mg), perphenazine (20.8 mg), or ziprasidone (112.8 mg), with dosage at the discretion of the study doctor. Mean modal doses in parentheses.
- Main Outcome: Discontinuation of treatment for any cause
- Results: Olanzapine group had statistically significant lower rate of discontinuation for any cause (84%) compared to other antipsychotics (70-76%). Quetiapine was associated with a significantly higher rate of metabolic side effects.
### Table 16. Pathophysiology of Schizophrenia vs. Mechanism of Action of Antipsychotics

<table>
<thead>
<tr>
<th>Brain Region</th>
<th>Pathophysiology in Schizophrenia</th>

</tr>
</tbody>
</table>

**Advantages**
- Low incidence of EPS at lower doses (<8 mg)
- Better overall efficacy compared to haloperidol
- Well tolerated
- Low incidence of EPS and TD

**Disadvantages**
- SE: insomnia, agitation, EPS, H/A, anxiety, prolactin, postural hypotension, constipation, dizziness, weight gain
- SE: mild sedation, insomnia, dizziness, minimal anticholinergic, early AST and ALT elevation, restlessness
- Weight gain associated with increased risk of diabetes mellitus and hyperlipidemia

**Comments**
- Quick dissolve (M-tabs), and long-acting (Consta®) formulations available
- Quick dissolve formulation (Zydis®) used commonly in ER setting for better compliance
- IM form available

**Note:** Risk of weight gain: Clozapine > Olanzapine > Quetiapine > Risperidone

Table 19. Side Effects of Antipsychotics

<table>
<thead>
<tr>
<th>System</th>

</tr>
</tbody>
</table>

Neuroleptic Malignant Syndrome (NMS)
- psychiatric emergency
- due to massive dopamine blockade; increased incidence with high potency and depot neuroleptics
- risk factors
  - medication factors
    - sudden increase in dosage, or starting a new drug
  - patient factors
    - medical illness
    - dehydration
    - exhaustion
    - poor nutrition
    - external heat load
    - sex: male
    - age: young adults

Anticholinergic Effects
- Red as a beet
- Hot as a hare
- Dry as a bone
- Blind as a bat
- Mad as a hatter

Metabolic and Cardiovascular Adverse Effects Associated with Antipsychotic Drugs
- Nat Rev Endocrinol 2012;8:114-126
- Study: Review
- Conclusions: All antipsychotics can cause cardiovascular and metabolic side effects, such as obesity, dyslipidemia, hyperglycemia and metabolic syndrome. Olanzapine and clozapine are most likely to cause these side effects. The mechanism that underlies the metabolic and cardiovascular effects is not fully understood, however, the histamine, dopamine, serotonin and muscarinic receptors are implicated.
• clinical presentation
  - mental status changes (usually occur first), fever, autonomic reactivity, rigidity
  - develops over 24-72 h
  - labs: increased creatine phosphokinase, leukocytosis, myoglobinuria
• treatment: discontinue drug, hydration, cooling blankets, dantrolene (hydrantoin derivative, used as a muscle relaxant), bromocriptine (DA agonist)
• mortality: 5%

Extrapyramidal Symptoms (EPS)

• incidence related to increased dose and potency
• acute (early-onset; reversible) vs. tardive (late-onset; often irreversible)

<table>
<thead>
<tr>
<th>Table 20 Extrapyramidal Symptoms</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dystonia</strong></td>

<tr>
<td><strong>Treatment</strong></td>
</tr>
</tbody>
</table>

Antiparkinsonian Agents (Anticholinergic Agents)

• types
  - benztropine (Cogentin®) 2 mg PO, IM or IV OD (~1-6 mg)
  - amantadine (Symmetrel®) 100 mg PO bid (100-400 mg)
  - diphenhydramine (Benadryl®) 25-50 mg PO/IM qid
• do not always prescribe with neuroleptics
  - give only if at high risk for acute EPS or if acute EPS develops
• do not give these for tardive syndromes because they worsen the condition

Antidepressants

• onset of effect
  - relief of neurovegetative symptoms: 1-3 wk
  - relief of emotional/cognitive symptoms: 2-6 wk
• may use mild stimulant (e.g. methylphenidate) for severe neurovegetative symptoms briefly and taper down as antidepredant effect increases
• taper TCAs slowly (over weeks-months) because they can cause withdrawal reactions
• tapering of any kind of antidepressant may be required based on the half-life of the medication and the patient’s individual sensitivity
• it is important to be particularly vigilant over the first 2 wk of therapy as neurovegetative symptoms may start to resolve while emotional and cognitive symptoms may not (patients may be particularly at risk for suicidal behaviour during this time)
• treatment of bipolar depression:
  - monotherapy with antidepressants is not advisable as a switch from depression to mania can occur
  - patients with bipolar disorder should only be treated with an antidepressant if it is combined with a mood stabilizer and antipsychotic
  - for patients taking mood stabilizers or antipsychotics, consider adding or switching to lithium or lamotrigine, or adding an SSRI or buproprion

Features of Neuroleptic Malignant Syndrome

FARM
- Fever
- Autonomic changes (e.g. increased HR/ BP, sweating)
- Rigidity of muscles
- Mental status changes (e.g. confusion)

FARM symptoms are also seen in Serotonin Syndrome (SS).

SS can be distinguished from NMS by the following:

<table>
<thead>
<tr>
<th>SS</th>
<th>NMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Twitchy, shivering, restless</td>
<td>Severe global rigidity</td>
</tr>
<tr>
<td>Flushed, sweaty</td>
<td>Pallor</td>
</tr>
<tr>
<td>Vomiting, diarrhea, abdominal pain</td>
<td>No GI symptoms</td>
</tr>
</tbody>
</table>

Tardive Dyskinesia may include grimacing, tongue protrusion, lip smacking, and rapid eye movement.

Selective Serotonin Reuptake Inhibitors (SSRIs) versus Other Antidepressants for Depression

Cochrane DB Syst Rev 2004; Issue 3
This systematic review of 98 RCTs compared the efficacy of SSRIs with other kinds of antidepressants in the treatment of patients with depressive disorders.

Conclusions: There is no significant difference in the effectiveness of SSRIs versus TCAs. Consider relative patient acceptability, toxicity and cost when choosing.
Table 21. Common Antidepressants

(SSRI=selective serotonin reuptake inhibitors; SNRI=serotonin and norepinephrine reuptake inhibitors; NDRI=norepinephrine and dopamine reuptake inhibitors; TCA=tricyclic antidepressants; MAOI= monoamine oxidase inhibitors; RIMA=reversible inhibition of MAO-A; NASSA=noradrenergic and specific serotonin antagonists)

Tips On Choosing Antidepressants
- All SSRI s have similar effectiveness, but consider side effect profiles and half-lives
- Bupropion causes less sexual dysfunction, weight gain, and sedation but is contraindicated for patients with history of seizure, stroke, brain tumour, brain surgery or closed head injury. Also used to treat eating disorders. Not recommended for anxiety because of stimulating effects
- Mirtazapine useful if insomnia or agitation are prominent, or to treat depression with cachexia
- Tramadol mainly used as adjunct for SSRI-induced sleep disturbances
- Sertraline, citalopram, and escitalopram have the least interactions with other drugs and are sleep-wake neutral
- Fluoxetine and paroxetine are the most activating drugs and should be taken in the morning
- Fluvoxamine is always sedating and should be taken in the evening

How Long to Treat?
6-12 mo: if first or second episode.
2 yr: third episode, elderly, psychotic features, refractory depression, > 2 episodes in 5 yr.

</tbody>
</table>
- optimization: ensuring adequate drug doses for the individual
- augmentation: the addition of a medication that is not considered an antidepressant to an antidepressant regimen (e.g. thyroid hormone, lithium, atypical antipsychotics)
- combination: the addition of another antidepressant to an existing treatment regimen (e.g. the addition of bupropion to an SSRI or SNRI)
- substitute: change in the primary antidepressant (within or outside a class)
- note: it is important to fully treat the symptoms of depression in order to decrease rates and severity of relapses

<td>Drugs that reduce seizure threshold: antipsychotics, systemic steroids, quinolone antibiotics, antimalarial drugs</td>
<td>MAOI, SSRI, SNRI, RIMA</td>
</tr>
</tbody>
</table>
Serotonin Syndrome
- thought to be due to over-stimulation of the serotonergic system
- can result from medication combinations such as SSRI + MAOI, SSRI + tryptophan, MAOI + meperidine, MAOI + tryptophan
- rare but potentially life-threatening adverse reaction to SSRIs, especially when switching from an SSRI to an MAOI
- symptoms include nausea, diarrhea, palpitations, chills, restlessness, confusion, and lethargy but can progress to myoclonus, hyperthermia, rigor and hypertonicity
- treatment: discontinue medication and administer emergency medical care as needed
- important to distinguish from NMS (see sidebar, PS44)

Discontinuation Syndrome
- caused by the abrupt cessation of an antidepressant
- observed most frequently with paroxetine, fluvoxamine, and venlafaxine
- symptoms usually begin within 1-3 d and include: anxiety, insomnia, irritability, mood lability, N/V, dizziness, headache, dystonia, tremor, chills, fatigue, lethargy and myalgia
- treatment: symptoms may last between 1-3 wk, but can be relieved within 24 h by restarting antidepressant therapy at the same dose the patient was taking and initiating a slow taper over several weeks
- consider drug with longer half-life such as fluoxetine

**Mood Stabilizers**

First-Line
Lithium or Valproic Acid (± antipsychotic)
- before initiating, get baseline: CBC, ECG (if patient >45 yr old or cardiovascular risk), urinalysis, BUN, Cr, electrolytes, TSH
- before initiating lithium: screen for pregnancy, thyroid disease, seizure disorder, neurological, renal, cardiovascular diseases
- may need acute coverage with benzodiazepines or antipsychotics
- use carbamazepine in non-responders and rapid cycling bipolar disorder
- can combine lithium and carbamazepine or valproic acid safely in lithium non-responders
- olanzapine may be used as a mood stabilizer, in conjunction with other mood stabilizers
- lithium and lamotrigine have established antidepressant efficacy

Lithium Toxicity (see Table 23)
- clinical diagnosis as toxicity can occur at therapeutic levels
  - common causes
    - overdose
    - sodium or fluid loss
    - concurrent medical illness
  - clinical presentation
    - GI: severe nausea/vomiting and diarrhea
    - cerebellar: ataxia, slurred speech, lack of coordination
    - cerebral: drowsiness, myoclonus, choreiform or Parkinsonian movements, upper motor neuron signs, seizures, delirium, coma
  - management
    - discontinue lithium for several doses and begin again at a lower dose when lithium level has fallen to a non-toxic range
    - serum lithium levels, BUN, electrolytes
    - saline infusion
    - hemodialysis if lithium >2 mmol/L, coma, shock, severe dehydration, failure to respond to treatment after 24 h, or deterioration

Second-Line/Adjuvant Mood Stabilizers
Lithium, lamotrigine, divalproex, carbamazepine

**Symptoms of Antidepressant Discontinuation**
FINISH
Flu-like symptoms
Insomnia
Nausea
Imbalance
Sensory disturbances
Hyperarousal (anxiety/agitation)

**Sequenced Treatment Alternatives to Relieve Depression**
Study: Prospective randomized anti-depressant treatment trial.
Patients: 4000 patients with major depressive disorder.
Objective: To compare the efficacy and tolerability of various antidepressant therapies through four sequential treatment levels.
Intervention: Level 1-citalopram → if relapse → Level 2-citalopram + bupropion SR, sertraline, venlafaxine XR, or cognitive psychotherapy. Level 2A-switch to bupropion or venlafaxine XR. Level 3-either mirtazapine or nortriptyline + lithium, T3. Level 4-tranylcypromine or venlafaxine XR + mirtazapine.
Results: Remission rates were 28% for Level 1, 17% for Level 2, 12-25% for Level 3, and 7-14% for Level 4. When more treatment steps are required, there are lower remission rates, greater degrees of tolerance, and higher rates of relapse.

Long term lithium use can lead to a nephropathy and diabetes insipidus in some patients.

**Lithium Side Effects**
Lithivm
Leukocytosis
Insipidus (diabetes)
Tremor, teratogenicity
Hyperthyroidism
Increased weight
“V”omiting, nausea
Miscellaneous (e.g. ECG changes, acne)

### Anxiolytics

- **anxiolytics** mask or alleviate symptoms; they do not cure them
- **indications**
  - short term treatment of transient forms of anxiety disorders, insomnia, alcohol withdrawal (especially delirium tremens), barbiturate withdrawal, organic brain syndrome (agitation in dementia), EPS and akathisia due to antipsychotics, seizure disorders, musculoskeletal disorders
- **relative contraindications**
  - major depression (except as an adjunct to other treatment), history of drug/alcohol abuse, pregnancy, breast feeding
- **mechanism of action**
  - benzodiazepines: potentiates binding of GABA to its receptors; results in decreased neuronal activity
  - buspirone: partial agonist of 5-HT1A receptors

### Benzodiazepines

- should be used for limited periods (weeks-months) to avoid dependence
- all benzodiazepines are sedating; be wary in use for the elderly
- have similar efficacy, so choice depends on half-life, metabolites and route of administration, OD or bid
- taper slowly over weeks-mo because they can cause withdrawal reactions
- low dose withdrawal: tachycardia, hypertension, panic, insomnia, anxiety, impaired memory and concentration, perceptive disturbances
- high dose withdrawal: hyperpyrexia, seizures, psychosis, death
- avoid alcohol because of potentiation of CNS depression; caution with drinking and use of machinery
• side effects
  • CNS: drowsiness, cognitive impairment, reduced motor coordination, memory impairment
  • physical dependence, tolerance develops
• withdrawal
  • symptoms: anxiety, insomnia, autonomic hyperactivity (less common)
  • onset: 1-2 d (short-acting), 2-4 d (long-acting)
  • duration: weeks/months
  • complications: above 50 mg diazepam/day: seizures, delirium, arrhythmias, psychosis
  • management: taper with long-acting benzodiazepine
  • similar to but less severe than alcohol withdrawal; can be fatal
• overdose
  • commonly used drug in overdose
  • overdose is rarely fatal
  • benzodiazepines are more dangerous and may cause death when combined with alcohol, other CNS depressants or TCAs

Benzodiazepine Antagonist – Flumazenil (Anexate®)
• use for suspected benzodiazepine overdose
• specific antagonist at the benzodiazepine receptor site

Buspirone (Buspar®)
• primary use: GAD
• may be preferred over benzodiazepines because:
  • non-sedating
  • no interaction with alcohol
  • does not alter seizure threshold
  • not prone to abuse
• onset of action: 2 wk
• side effects: dizziness, drowsiness, nausea, headache, nervousness, EPS

**Electroconvulsive Therapy**
• induction of a grand mal seizure using an electrical pulse through the brain while the patient is under general anesthesia with a muscle relaxant
• unilateral vs. bilateral electrode placement
• indications
  • depression refractory to adequate pharmacological trial
  • high suicide risk
  • medical risk in addition to depression (dehydration, electrolytes, pregnancy)
  • previous good response to ECT
  • familial response to ECT
  • elderly

**Benzodiazepines used for Alcohol Withdrawal**
• Diazepam 20 mg PO/IV q1h prn
• Lorazepam 2-5 mg PO/IV/SI for patients with liver disease, chronic lung disease, or elderly

**Geriatric Benzodiazepines**
LOT
lorazepam
Oxazepam
Temazepam
Safe in liver disease because not metabolized by liver

**ECT in Society**
Prior to the 1940’s, ECT was performed without the use of muscle relaxants, resulting in seizures with full-scale convulsions and rare but serious complications such as vertebral and long-bone fractures. This practice may have led to negative societal perceptions of ECT, further perpetuated by barbaric depictions in popular culture. Despite ongoing stigmatization, ECT as it is practiced today is an effective and safe option for patients struggling with mental illness.
- psychotic depression
- catatonic features
- marked vegetative features
- acute schizophrenia
- mania unresponsive to medications
- side effects: risk of anesthesia, memory loss (may be retrograde and/or anterograde, tends to resolve by 6 to 9 mo, permanent impairment controversial), headaches, myalgias
- evidence that unilateral ECT causes less memory loss than bilateral but may not be as effective
- contraindications: increased intracranial pressure

### Experimental Therapies

**Deep Brain Stimulation (DBS)**
- constant electrical stimulation of neuroanatomical targets that have been identified in the biological model of depression
- areas identified include the nucleus accumbens, internal capsule and subgenual cingulate cortex
- parameters such as active electrode location, pulse width, frequency and voltage may be manipulated

**Transcranial Magnetic Stimulation (TMS)**
- non-invasive magnetic stimulation of superficial neurons in the frontal cortex (main target: dorsolateral prefrontal cortex) hypothesized to normalize cortical activity in depressed patients
- meta-analyses show modest acute efficacy

**Vagal Nerve Stimulation**
- an invasive surgical procedure: a battery powered pulse generator is implanted in the chest wall and connected to an electrode that is attached around one (typically the left) vagus nerve
- meta-analyses show a greater response and remission rates for treatment resistant depression if combined with usual treatment (versus usual treatment alone)
- not indicated for use in acute illness

### Canadian Legal Issues

</tbody>
</table>

**Form 1: Application for Psychiatric Assessment**
- Filled out when a patient is suspected of being an imminent harm to themselves (suicide) or others (homicide) or when they are incapable of self-care (e.g. not dressed for freezing weather) and are suffering from an apparent mental disorder
- Based on any combination of the physician’s own observations and facts communicated by others
- Box A or Box B completed
- Box A: Serious Harm Test
- The Past/Present Test assesses current behaviours/threats/attempts
- The Future Test assesses the likelihood of serious harm occurring as a result of the presenting mental disorder. In this section, one should document evidence of the mental disorder
- Box B: Patients with a known mental disorder, who are incapable of consenting to treatment (existing substitute decision-maker), have previously received treatment and improved, and are currently at risk of serious harm due to the same mental disorder

* Schedule 1 Facilities: Able to provide intensive inpatient and outpatient care

Consent

- see [Ethical, Legal and Organizational Aspects of Medicine, ELOAM5](#)

Community Treatment Order (CTO)

- known as “Brian’s Law,” Ontario passed legislature regarding CTOs on December 1, 2000
- similar CTOs have been implemented in Saskatchewan (1995), Manitoba (1997) and British Columbia (1999)
- purpose: to provide a person who suffers from a serious mental disorder with a comprehensive plan of community-based treatment and supervision that is less restrictive than being detained in a psychiatric facility
- intended for those who:
  - as a result of their serious mental disorder, experience a pattern of admission to a psychiatric facility where their condition is usually stabilized
  - after being released, these patients often lack supervision and stop treatment
  - due to the destabilization of their condition, these patients usually require re-admission to hospital
- criteria for a physician to issue a CTO
  - patient with a prior history of hospitalization
  - a community treatment plan for the person has been made
  - examination by a physician within the previous 72 h before entering into the CTO plan
  - ability of the person subject to the CTO to comply with it
  - consultation with a rights adviser and consent of the person and the person’s substitute decision maker, if any
- CTOs are valid for 6 mo unless they are renewed or terminated at an earlier date
  - where the person fails to comply with the CTO
  - when the person or his/her substitute decision-maker withdraws consent to the community treatment plan
- CTO process is consent-based and all statutory protections governing informed consent apply
- the rights of a person subject to a CTO include:
  - the right to a review by the Consent and Capacity Board with appeal to the courts each time a CTO is issued or renewed
  - a mandatory review by the Consent and Capacity Board every second time a CTO is renewed
  - the right to request a re-examination by the issuing physician to determine if the CTO is still necessary for the person to live in the community
  - the right to review findings of incapacity to consent to treatment
  - provisions for rights advice

Pulmonary Function Tests (PFTs)

- useful in differentiating the pattern of lung disease (obstructive vs. restrictive) (Table 6)
- assess lung volumes, flow rates, and diffusion capacity (see Figures 4a and 4b)
- note: normal values for FEV₁ are approximately ±20% of the predicted values (for age, sex and height); ethnicity may affect predicted values

*Bronchiectasis can be obstructive or mixed

Plethysmography: involves the use of a plethysmograph (or “body box”) and used to measure FRC. After a normal expiration the patient inhales against a closed mouthpiece. Resultant changes in the volume and pressure of the plethysmograph are used to calculate the volume of gas in the thorax. Useful for patients with air trapping since all air in the thoracic cavity is determined by the calculation.

He dilution: used to measure FRC by diluting a known amount of helium into a patient’s lungs following inspiration. Since the amount of helium remains constant, FRC is determined based on the final concentration of the helium in the closed system. Only includes airspaces that communicate with the bronchial tree.

Bronchoscopy: a flexible or rigid bronchoscope is used for visualization of a patient’s airways for diagnostic and therapeutic indications. It is used to obtain tissue washings for culture and cytology, endobronchial or transbronchial tissue biopsies, remove secretions/foreign bodies/blood, laser resections, airway stenting, etc. Mediastinal lymph nodes can also be sampled using a special bronchoscope equipped with an U/S probe (EBUS).

</tr>
</tbody>
</table>

Lung Volumes

- **ERV** – Expiratory Reserve Volume
- **FFR** – Forcible Expiratory Flow Rate
- **FEV₁** – Forcible Expiratory Volume (in one second)
- **FRC** – Functional Residual Capacity
- **IC** – Inspiratory Capacity
- **RV** – Residual Volume
- **TLC** – Total Lung Capacity
- **VC** – Vital Capacity
- **V₁** – Tidal Volume
Arterial Blood Gases

- provides information on acid-base and oxygenation status
- see also Nephrology, NP14

Approach to Acid-Base Status

1. Is the pH acidemic (pH < 7.35), alkalemic (pH > 7.45), or normal (pH 7.35-7.45)?
   - metabolic: change in HCO₃⁻ and pH in same direction
   - respiratory: change in HCO₃⁻ and pH in opposite direction

2. What is the primary disturbance?
   - metabolic compensation occurs over 2-3 d reflecting altered renal HCO₃⁻ production and excretion
   - respiratory compensation through ventilatory control of PₐCO₂ occurs immediately
   - inadequate compensation may indicate a second acid-base disorder

<table>
<thead>
<tr>
<th>Disturbance</th>
<th>PₐCO₂ (mmHg)</th>
<th>HCO₃⁻ (mmHg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Respiratory Acidosis</td>
<td>↑ 10</td>
<td>↑ 1</td>

</tr>
<tr>
<td>Metabolic Acidosis</td>
<td>↓ 1</td>
<td>↓ 1</td>
</tr>
<tr>
<td>Metabolic Alkalosis</td>
<td>↑ 5-7</td>
<td>↑ 10</td>
</tr>
</tbody>
</table>

4. If there is metabolic acidosis, what is the anion gap and osmolar gap?
   - anion gap = [Na⁺]–([Cl⁻]+[HCO₃⁻]); normal ≤10-15 mmol/L
   - osmolar gap = measured osmolarity – calculated osmolarity = measured – (2[Na⁺] + glucose + urea); normal ≤10

5. If anion gap is increased, is the change in bicarbonate the same as the change in anion gap?
   - if not, consider a mixed metabolic picture

Table 8. Expected Compensation for Specific Acid-Base Disorders

- see Nephrology, NP14 for differential diagnosis of metabolic acidosis and alkalosis

Diffusion Capacity for Carbon Monoxide (DLCO)
DLCO decreases with:
- Decreased surface area (e.g. emphysema)
- Decreased hemoglobin
- Interstitial lung disease
- Pulmonary vascular disease
DLCO increases with:
- Asthma
- Pulmonary hemorrhage
- Polythemia
- Increased pulmonary blood volume

Note: Mixed acid-base disturbances can still have a “normal pH”

Ventilation Failure:
Think “Can’t Breathe” vs. “Won’t Breathe” (increased PₐCO₂)
Can’t Breathe
- Neuromuscular disorders
- Airway obstruction
- Parenchymal disease
Won’t Breathe
- Respiratory centre depression
- Hypothyroidism
- Sleep apnea (central)

Cyanide, Carbon dioxide
Alcoholic ketoacidosis
Tokena, Theophylline

Acidosis ↔ Hyperkalemia
Alkalosis ↔ Hypokalemia

- see Nephrology, NP14 for differential diagnosis of metabolic acidosis and alkalosis
Approach to Hypoxemia

1. $P_aO_2$: What is the arterial oxygen tension? (Measured by ABG. Normal = 95-100 mmHg)
2. A-aDO$_2$: What is the oxygen gradient between alveoli and pulmonary capillaries? (Calculate. See sidebar. Normal <15 mmHg but increases with age)
3. What is the cause of the hypoxemia? (see Figure 7)

Figure 7. Approach to hypoxemia

Figure 8. Pathophysiology of shunt

Diseases of Airway Obstruction

Pneumonia

• see Infectious Diseases, ID8

Asthma

• see also Family Medicine, FM16 and Pediatrics, P94

Definition

• chronic inflammatory disorder of the airways resulting in episodes of reversible bronchospasm causing airflow obstruction
• associated with reversible airflow limitation and airway hyper-responsiveness to endogenous or exogenous stimuli

Epidemiology

• common, 7-10% of adults, 10-15% of children
• most children with asthma significantly improve in adolescence
• often family history of atopy (asthma, allergic rhinitis, eczema)
• occupational asthma (organic allergies, isocyanates, animals, etc.)
Pathophysiology
- airway obstruction → V/Q mismatch → hypoxemia → ↑ ventilation → ↓ P\textsubscript{a}CO\textsubscript{2} → ↑ pH and muscle fatigue → ↓ ventilation, ↑ P\textsubscript{a}CO\textsubscript{2}/↓ pH

Triggers
- URTIs, allergens (pet dander, house dust, moulds), irritants (cigarette smoke, air pollution), drugs (NSAIDs, β-blockers), preservatives (sulphites, MSG), other (emotion/anxiety, cold air, exercise, GERD)

Signs and Symptoms
- dyspnea, wheezing, chest tightness, cough (especially nocturnal), sputum
- symptoms can be paroxysmal or persistent
- signs of respiratory distress (see sidebar R3)
- pulsus paradoxus

Table 11. Criteria for Determining if Asthma is Well Controlled

<table>
<thead>
<tr>
<th>Daytime symptoms &lt;4 d/wk</th>
<th>Night-time symptoms &lt;1 night/wk</th>
<th>Physical activity normal</th>
<th>Exacerbations mild, infrequent</th>
</tr>
</thead>
<tbody>
<tr>
<td>No asthma-related absence from work/school</td>
<td>↓ FEV\textsubscript{1}/FVC &lt; lower limit of normal (&lt;0.75 to 0.8 in adults, &lt;0.8-0.9 in children age 6+)</td>
<td>FEV\textsubscript{1} or PEF &gt;90% of personal best</td>
<td>PEF diurnal variation &lt;10-15%</td>
</tr>
</tbody>
</table>

Adapted from Can Respir J 2012; 19:127-164

Investigations
- O\textsubscript{2} saturation
- ABGs (consider in acute exacerbation, along with peak flows, in Emergency Department) decreased P\textsubscript{a}CO\textsubscript{2} during attack (V/Q mismatch)
  - decreased P\textsubscript{a}CO\textsubscript{2} in mild asthma (hyperventilation)
  - normal or increased P\textsubscript{a}CO\textsubscript{2} is an ominous sign: patient is no longer able to hyperventilate (worsened airway obstruction or respiratory muscle fatigue)
- PFTs (do when stable) (see Table 12)

Table 12. Pulmonary Function Criteria for Diagnosis of Asthma

<table>
<thead>
<tr>
<th>Preferred Measurement</th>
<th>Alternative Measurements</th>

<td>(2) Post-exercise: ↓ FEV\textsubscript{1} ≥10-15%</td>
</tr>
</tbody>
</table>

Adapted from Can Respir J 2012; 19:127-164

Treatment
- environment: avoid triggers
- patient education: features of the disease, goals of treatment, self-monitoring
- pharmacological
  - symptomatic relief in acute episodes: short-acting β\textsubscript{2}-agonist, anticholinergic bronchodilators, oral steroids, addition of a long acting β\textsubscript{2}-agonist
  - long-term prevention: inhaled/oral corticosteroids, anti-allergic agents, long-acting β\textsubscript{2}-agonists, methylxanthine, LTRA, anti-IgE antibodies (e.g. Xolair®)

Adapted from Can Respir J 2012; 19:127-164

Environmental Control, Education, and Written Action Plan

Emergency Management of Asthma (see also Emergency Medicine, ER30)
1. inhaled β2-agonist first line (MDI route and spacer device recommended)
2. systemic steroids (PO or IV, if severe)
3. add anticholinergic therapy ± magnesium sulphate
4. rapid sequence intubation in life-threatening cases (plus 100% O₂, monitors, IV access)
5. SC/IV adrenaline, IV salbutamol if unresponsive
6. corticosteroid therapy at discharge

Chronic Obstructive Pulmonary Disease (COPD)

- see also Family Medicine, FM16

Definition
- progressive, and irreversible condition of the lung characterized by chronic obstruction to airflow with many patients having periodic exacerbations, gas trapping, lung hyperinflation and weight loss
- 2 subtypes (chronic bronchitis or emphysema): usually coexist to variable degrees
- gradual decrease in FEV₁ over time with episodes of acute exacerbations

Table 13. Clinical and Pathologic Features of COPD*

<table>
<thead>
<tr>
<th>Chronic Bronchitis</th>
<th>Emphysema</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defined clinically: Productive cough on most days for at least 3 consecutive months in 2 successive years Obstruction is due to narrowing of the airway lumen by mucosal thickening and excess mucus</td>
<td></td>
</tr>
<tr>
<td>Defined pathologically: Dilation and destruction of air spaces distal to the terminal bronchiole without obvious fibrosis Decreased elastic recoil of lung parenchyma causes decreased expiratory driving pressure, airway collapse, and air trapping</td>
<td></td>
</tr>
<tr>
<td>2 types: 1) Centriacinar (respiratory bronchioles predominantly affected) Typical form seen in smokers, primarily affects upper lung zones 2) Panacinar (respiratory bronchioles, alveolar ducts, and alveolar sacs affected) Accounts for about 1% of emphysema cases α₁-antitrypsin deficiency, primarily affects lower lobes</td>
<td></td>
</tr>
</tbody>
</table>

*Note that both chronic bronchitis and emphysema can exist without obstruction. Only if obstruction is also present is it termed COPD

**Note that both chronic bronchitis and emphysema can exist without obstruction. Only if obstruction is also present is it termed COPD

Natural Progression of COPD

40s Chronic productive cough, wheezing occasionally
50s 1st acute chest illness
60s Dyspnea on exertion, increasing sputum, more frequent exacerbations
Late Hypoxemia with cyanosis, polycythemia, hypercapnia (morning headaches, cor pulmonale, weight loss

Remember, first line therapy for COPD is smoking cessation.
**Risk Factors**
- smoking is #1 risk factor
- others:
  - environmental: air pollution, occupational exposure, exposure to wood smoke or other bioaerosols, secondhand smoke
  - treatable factors: α-antitrypsin deficiency, bronchial hyperactivity
  - demographic factors: age, family history, male sex, history of childhood respiratory infections, low socioeconomic status

### Signs and Symptoms

#### Table 14. Clinical Presentation and Investigations for Chronic Bronchitis and Emphysema

<table>
<thead>

<td>Decreased diaphragmatic excursion</td>
<td></td>
</tr>
</tbody>
</table>

*Note that the distinction between “blue bloaters” and “pink puffers” is more of historical than practical interest as most COPD patients have elements of both.

#### Table 15. Treatment of Stable COPD

<table>
<thead>
<tr>
<th>Treatment</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smoking cessation</td>
<td>Nicotine replacement, bupropion, varenicline</td>
</tr>
<tr>
<td>Home oxygen</td>
<td>Prevents cor pulmonale and decreases mortality if used &gt; 15% of time; indicated if (1) P₉₀₂ &lt; 55 mmHg or (2) ≥ 60 mmHg with cor pulmonale or polycythemia</td>
</tr>
</tbody>
</table>

**SYMPTOMATIC RELIEF** (no mortality benefit)

- Bronchodilators (mainstay of current drug therapy, used in combination):
  - Short-acting anticholinergics (e.g. ipratropium bromide) and short-acting β₂-agonists (e.g. salbutamol, terbutaline)
  - LABAs (e.g. salmeterol, formoterol, indacaterol) and long-acting anticholinergics (e.g. tiotropium bromide, glycopyrronium bromide)
  - More sustained effects for moderate to severe COPD
- Inhaled corticosteroids (ICS) + LABA combination (e.g. Advair®: fluticasone + salmeterol, Symbicort®: budenoside + formoterol):
  -ICS/LABA increases effectiveness vs. LABA alone
- Theophylline: weak bronchodilator; limited evidence to suggest combination with bronchodilator
- Side effects: nervous tremor, nausea/vomiting/diarrhea, tachycardia, arrhythmias, sleep changes
- PDE4 inhibitor: rufinum (Daxas®) – weak bronchodilator

- Corticosteroids:ICS monotherapy is contraindicated and ICS should only be used with a LABA in combination in patients with a history of exacerbations
- COPD airways are usually inflamed but often not responsive to steroids, therefore avoid chronic systemic glucocorticoids (although oral steroids are very important when treating exacerbations)

- Surgical:
  - Lung volume reduction surgery (section of emphysematous parts of lung, associated with further mortality if FEV₁ < 20%)
  - Lung transplant
  - Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance

- Other:
  - Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance

---

**α-1-Antitrypsin Deficiency**

Inherited disorder of defective production of α₁-antitrypsin, a protein produced by hepatocytes. Acts in the alveolar tissue by inhibiting the action of proteases from destroying alveolar tissue. When deficient, proteases can destroy lung alveoli resulting in emphysema.

**Pulmonary Embolism in Patients with Unexplained Exacerbation of COPD**

**Non-invasive Positive Pressure Ventilation for Treatment of Respiratory Failure due to Exacerbations of COPD**

**Primary Outcome:** Treatment failure, mortality, and tracheal intubation.

**Results:** The risks for all primary outcomes were reduced in the NPPV group. The results for mortality were significant (RR 0.52; 95% CI 0.32–0.85), and hospital length of stay was reduced in the NPPV group (0.61 vs. 0.87 days; RR 0.76; 95% CI 0.61–0.95). The results for treatment failure and tracheal intubation were also significant (RR 0.68; 95% CI 0.51–0.91, and RR 0.61; 95% CI 0.45–0.83, respectively).

**Conclusion:** Non-invasive positive pressure ventilation (NPPV) is effective in reducing mortality and tracheal intubation in patients with severe exacerbations of COPD.
Acute Exacerbations of COPD

- definition
  - sustained (>24-48 h) worsening of dyspnea, cough, or sputum production leading to an increased use of medications
- etiology: viral URI, bacteria, air pollution, CHF, PE, MI must be considered
- management
  - ABCs, consider assisted ventilation if decreasing LOC or poor ABGs
  - O₂: target 88-92% SaO₂ for CO₂ retainers
  - bronchodilators by MDI with spacer or nebulizer
  - SABA + anticholinergic, e.g. salbutamol and ipratropium bromide via nebulizers x 3 back-to-back
  - systemic corticosteroids: IV solumedrol or oral prednisone
  - antibiotics if purulent sputum
  - simple exacerbation (no risk factors): amoxicillin, 2nd or 3rd generation cephalosporin, macrolide, or TMP/SMX
  - complicated exacerbation (one of: FEV₁ ≤50% predicted, ≥4 exacerbations per year, ischemic heart disease, home O₂ use, chronic oral steroid use): fluoroquinolone or β-lactam + β-lactamase inhibitor (amoxicillin/clavulanate)
  - post exacerbation: rehabilitation with general conditioning to improve exercise tolerance
- ICU admission
  - for life threatening exacerbations
  - ventilatory support
  - non-invasive: NPPV, BiPAP
  - conventional mechanical ventilation

Prognosis in COPD

- prognostic factors
  - level of dyspnea is the single best predictor
  - development of complications, e.g. hypoxemia or cor pulmonale
  - 5-yr survival
    - FEV₁ <1.0 L = 50%
    - FEV₁ <0.75 L = 33%
  - BODE index for risk of death in COPD
    - greater score = higher probability the patient will die from COPD; score can also be used to predict hospitalization
    - 10 point index consisting of four factors:
      - Body mass index (BMI): <21 (+1 point)
      - Obstruction (FEV₁): 50-64% (+1), 36-49% (+2), <35% (+3)
      - Dyspnea (MRC scale): walks slower than people of same age on level surface, stops occasionally (+1), stops at 100 yards or a few minutes on the level (+2), too breathless to leave house or breathless when dressing/undressing (+3)
      - Exercise capacity (6 minute walk distance): 250-349 m (+1), 150-249 m (+2), <149 m (+3)
- Number of exacerbations: correlate with increased use of medications, increased hospitalization, FEV₁. Increased exacerbations contribute data for analysis.
- There appears to be a reduction in influenza-related infections, as well as exacerbations in patients with COPD receiving the vaccine.

Remember to step down therapy to lowest doses which control symptoms/signs of bronchoconstriction.

Complications of COPD

- Polycythemia 2° to hypoxemia
- Chronic hypoxemia
- Pulmonary HTN from vasoconstriction
- Cor pulmonale
- Pneumothorax due to rupture of emphysematous bullae
**Bronchiectasis**

**Definition**
- irreversible dilatation of airways due to inflammatory destruction of airway walls resulting from persistently infected mucus
- usually affects medium sized airways
- *P. aeruginosa* is the most common pathogen; *S. aureus, H. influenzae* and nontuberculous mycobacteria also common

**Table 16. Etiology and Pathophysiology of Bronchiectasis**

<table>
<thead>

</tbody>
</table>

**Signs and Symptoms**
- chronic cough, purulent sputum (but 10-20% have dry cough), hemoptysis (can be massive), recurrent pneumonia, local crackles (inspiratory and expiratory), wheezes
- clubbing
- may be difficult to differentiate from chronic bronchitis

**Investigations**
- PFTs: often demonstrate obstructive pattern but may be normal
- CXR
  - nonspecific: increased markings, linear atelectasis, loss of volume in affected areas
  - specific: “tram tracking” – parallel narrow lines radiating from hilum, cystic spaces, honeycomb like structures
- high-resolution thoracic CT (diagnostic, gold standard):
  - 87-97% sensitivity, 93-100% specificity
  - “signet ring”: dilated bronchi with thickened walls where diameter bronchus > diameter of accompanying artery
- sputum cultures (routine + AFB)
- serum Ig levels
- sweat chloride if cystic fibrosis suspected (upper zone predominant)

**Treatment**
- vaccination: influenza and Pneumovax*
- antibiotics (oral, IV, inhaled): routinely used for mild exacerbations, driven by sputum sensitivity; macrolides may be used chronically for an anti-inflammatory effect
- inhaled corticosteroids: decrease inflammation and improve FEV₁
- oral corticosteroids for acute, major exacerbations
- chest physiotherapy, breathing exercises, physical exercise
- pulmonary resection: in selected cases with focal bronchiectasis

**Cystic Fibrosis (CF)**

- see also Pediatrics, P95

**Pathophysiology**
- chloride transport dysfunction: thick secretions from exocrine glands (lung, pancreas, skin, reproductive organs) and blockage of secretory ducts

**Clinical Features**
- results in severe lung disease, pancreatic insufficiency, diabetes and azoospermia
- other manifestations: meconium ileus in infancy, distal ileal obstruction in adults, sinusitis, liver disease
- chronic lung infections
  - *S. aureus*: early
  - *P. aeruginosa*: most common
  - *B. cepacia*: worse prognosis but less common
  - *Aspergillus fumigatus*

**Investigations**
- sweat chloride test
  - increased concentrations of NaCl and K⁺ ([Cl⁻] >60 mmol/L is diagnostic in children)
- heterozygotes have normal sweat tests (and no symptoms)
- PFTs
  - early: airflow limitation in small airways
  - late: severe airflow hyperinflation, gas trapping, decreased DLCO (very late)
• ABGs
  - hypoxemia, hypercapnia later in disease with eventual respiratory failure and cor pulmonale
• CXR
  - hyperinflation, increased pulmonary markings (especially upper lobes)

**Treatment**
- chest physiotherapy and postural drainage
- bronchodilators (salbutamol ± ipratropium bromide)
- inhaled mucolytic (reduces mucus viscosity), hypertonic saline DNase
- inhaled tobramycin
- antibiotics (e.g. ciprofloxacin)
- lung transplant
- pancreatic enzyme replacements

**Prognosis**
- depends on: infections (cepacia colonization), FEV1, acute pulmonary exacerbations, lung transplant vs. non-lung transplant

---

### Interstitial Lung Disease (ILD)

#### Pathophysiology
- inflammatory and/or fibrosing process in the alveolar walls → distortion and destruction of normal alveoli and microvasculature
- typically associated with:
  - lung restriction (decrease in TLC and VC)
  - decreased lung compliance (increased or normal FEV1/FVC)
  - impaired diffusion (decreased DLCO)
  - hypoxemia due to V/Q mismatch (usually without hypercapnia until end stage)
  - pulmonary HTN and cor pulmonale occur with advanced disease secondary to hypoxemia and blood vessel destruction

#### Etiology
- >100 known disorders can cause ILD
- majority due to unknown agents or cause

**Table 17. Interstitial Lung Diseases**

<table>
<thead>
<tr>

</tbody>
</table>

**In ILD think FASSTEN and BAD RASH**

**Upper Lung Disease (FASSTEN)**
- Farmer’s lung (hypersensitivity pneumonitis)
-ankylosing spondylitis
-Sarcoidosis
-Silicosis
-TB
-Eosinophilic granuloma (Langerhans cell histiocytosis)
-Neurofibromatosis

**Lower Lung Disease (BADRASH)**
- Bronchiolitis obliterans with organizing pneumonia (BOOP)
-Asbestosis
-Drugs (nitrofurantoin, hydralazine, INH, amiodarone, many chemo drugs)
-Rheumatologic disease
-Aspiration
-Scleroderma
-Hamman Rich (acute interstitial pneumonia) and IPF
Signs and Symptoms
- SOB, especially on exertion
- nonproductive cough
- crackles (dry, fine, end-inspiratory)
- clubbing (especially in IPF and asbestosis)
- features of cor pulmonale
- note that signs and symptoms vary with underlying disease process
  - e.g. sarcoidosis is seldom associated with crackles and clubbing

Investigations
- CXR/high resolution CT (see also Medical Imaging, MI7)
  - usually decreased lung volumes
  - reticular, nodular, or reticulonodular pattern (nodular < 3 mm)
  - hilar/mediastinal adenopathy (especially in sarcoidosis)
- PFTs
  - restrictive pattern: decreased lung volumes and compliance
  - normal or increased FEV1/FVC (>70-80%), i.e. flow rates are often normal or high when corrected for absolute lung volume
  - DLCO decreased due to V/Q mismatch less surface area for gas exchange ± pulmonary vascular disease
- ABGs
  - with progression of disease, hypoxemia and respiratory alkalosis may be present
- other
  - bronchoscopy, bronchoalveolar lavage, lung biopsy
  - ESR, ANA (lupus), RF (RA), serum-precipitating antibodies to inhaled organic antigens (hypersensitivity pneumonitis), c-ANCA (GPA), anti-GBM (Goodpasture’s)

Unknown Etiologic Agents

USUAL INTERSTITIAL PNEUMONIA (UIP) aka IDIOPATHIC PULMONARY FIBROSIS (IPF) aka CRYPTOGENIC FIBROSING ALVEOLITIS

Definition
- a progressive, irreversible condition characterized by fibrosis of lung parenchyma with no known cause
  - chest CT usually shows honeycomb lung, lung biopsy shows UIP (usual interstitial pneumonia) pattern
  - commonly presents over age 50, incidence rises with age; males > females
- DDx:
  - other idiopathic interstitial pneumonia, especially NSIP, but also COP and:
    - desquamative interstitial pneumonitis (DIP)
    - lymphocytic interstitial pneumonitis (LIP): usually 2nd to immune conditions such as HIV (mostly in children), Sjögren’s (now considered to be a hematological malignancy in most adult cases on a spectrum with lymphoma)

Signs and Symptoms
- commonly presents over age 50, incidence rises with age; males > females
- dyspnea on exertion, nonproductive cough, constitutional symptoms, late inspiratory fine crackles at lung bases, clubbing

Investigations
- labs (nonspecific, autoimmune serology usually negative)
- CXR: reticular or reticulonodular pattern with lower lung predominance; may appreciate honeycombing in advanced disease
- high resolution CT: lower zone peripheral reticular markings, traction bronchiectasis, honeycombing, ground glass not prominent in IPF
- biopsy: rarely for UIP as honeycombing makes radiologic diagnosis possible

Treatment
- O2
  - generally does not respond to immunosuppression
- N-acetylcysteine (anti-oxidant)
- lung transplantation for advanced disease
- mean survival of 3 to 5 yr after diagnosis

SARCOIDOSIS

Definition
- idiopathic non-infectious granulomatous multi-system disease with lung involvement in 90%
- characterized pathologically by non-caseating granulomas
- numerous HLA antigens have been shown to play a role and familial sarcoidosis is now recognized
Epidemiology
- typically affects young and middle-aged patients
- higher incidence among black Americans and people at northern latitudes e.g. Scandinavia, Canada

Signs and Symptoms
- asymptomatic, cough, dyspnea, fever, arthralgia, malaise, erythema nodosum, chest pain
- chest exam often normal
- common extrapulmonary manifestations
  - cardiac (arrhythmias, sudden death)
  - eye involvement (anterior or posterior uveitis)
  - skin involvement (skin papules, erythema nodosum, lupus pernio)
  - peripheral lymphadenopathy
  - arthralgia
  - hepatomegaly ± splenomegaly
- less common extra-pulmonary manifestations involve bone, CNS and kidney
- two acute sarcoid syndromes
  - Lofgren's syndrome: fever, erythema nodosum, bilateral hilar lymphadenopathy, arthralgias
  - Heerfordt-Waldenstrom syndrome: fever, parotid enlargement, anterior uveitis, facial nerve palsy

Investigations
- CBC (cytopenias from spleen or marrow involvement)
- serum electrolytes, creatinine, liver enzymes, calcium (hypercalcemia/hypercalciuria due to vitamin D activation by granulomas)
- hypergammaglobulinemia, occasionally RF positive
- elevated serum ACE (non-specific and non-sensitive)
- CXR: predominantly nodular opacities especially in upper lung zones ± hilar adenopathy
- PFTs: normal, obstructive pattern, restrictive pattern with normal flow rates and decreased DLCO
- ECG: to rule out conduction abnormalities
- slit-lamp eye exam: to rule out uveitis

Diagnosis
- biopsy
  - transbronchial lung biopsy, transbronchial lymph node aspiration, endobronchial ultrasound guided surgical (EBUS) biopsy or mediastinoscopic lymph node biopsy or granulomas
- in ~75% of cases, transbronchial biopsy shows granulomas in the parenchyma even if the CXR is normal

Staging
- radiographic, based on CXR
  - Stage 0: normal radiograph
  - Stage I: bilateral hilar lymphadenopathy ± right paratracheal lymphadenopathy
  - Stage II: bilateral hilar lymphadenopathy and diffuse interstitial disease
  - Stage III: interstitial disease only (reticulonodular pattern or nodular pattern)
  - Stage IV: pulmonary fibrosis (honeycombing)

Treatment
- 85% of stage I resolve spontaneously
- 50% of stage II resolve spontaneously
- steroids for symptoms, declining lung function, hypercalcemia, or involvement of eye, CNS, kidney, or heart (not for abnormal CXR alone)
- methotrexate or other immunosuppressives occasionally used

Prognosis
- approximately 10% mortality secondary to progressive fibrosis of lung parenchyma

Known Etiologic Agents

HYPERSENSITIVITY PNEUMONITIS
- also known as extrinsic allergic alveolitis
- non-IgE mediated inflammation of lung parenchyma (acute, subacute, and chronic forms)
- caused by sensitization to inhaled agents, usually organic dust
- pathology: airway-centered, poorly formed granulomas and lymphocytic inflammation
- exposure usually related to occupation or hobby
  - Farmer's Lung (Thermophilic actinomycetes)
  - Bird Breeder's/Bird Fancier's Lung (Chlamydia psittaci in bird droppings)
  - Humidifier Lung (Aureobasidium pullulans)
  - Sauna Taker's Lung (Aureobasidium spp.)

Corticosteroids for Pulmonary Sarcoidosis
Cochrane DB Syst Rev 2005;CD001114
Study: Meta-analysis of 13 RCTs involving 1066 participants examining the use of steroids (oral or inhaled) in sarcoidosis.
Results: Oral steroids demonstrated an improvement in CXR (RR 1.46, 1.01 to 2.09). For inhaled corticosteroids, two studies showed no improvement in lung function and one study showed an improvement in diffusing capacity. No data on side-effects.
Conclusions: Oral steroids improve CXR findings and global scores of CXR, symptoms and sputum over 3-24 mo, but do not improve lung function or modify disease course. Oral steroids may be of benefit for patients with Stage 2 and 3 disease.
Signs and Symptoms
- acute presentation: (4-6 h after exposure)
  - dyspnea, cough, fever, chills, malaise (lasting 18-24 h)
  - CXR: diffuse infiltrates
- subacute presentation: more insidious onset than acute presentation
- chronic presentation
  - insidious onset
  - dyspnea, cough, malaise, anorexia, weight loss
  - PFTs: progressively restrictive
  - CXR: predominantly upper lobe reticulonodular pattern
- type IV (cell mediated, delayed hypersensitivity) reaction (see Rheumatology, RH2)
- in both acute and chronic reactions, serum precipitins may be detectable (neither sensitive nor specific)

Treatment
- early diagnosis: avoidance of further exposure is critical as chronic changes are irreversible
- systemic corticosteroids can relieve symptoms and speed resolution

PNEUMOCONIOSES
- reaction to inhaled inorganic dusts 0.5-5 µm in size
- no effective treatment, therefore key is exposure prevention through the use of protective equipment
- smoking cessation, annual influenza and pneumococcal vaccination, rehabilitation, lung transplant for endstage disease

Table 18. Pneumoconioses

ILD ASSOCIATED WITH DRUGS OR TREATMENTS

Drug-Induced
- antineoplastic agents: bleomycin, mitomycin, busulfan, cyclophosphamide, methotrexate, chlorambucil, BCNU (carmustine)
- antibiotics: nitrofurantoin, penicillin, sulfonamide
- cardiovascular drugs: amiodarone, tocaindide
- anti-inflammatory agents: methotrexate, penicillamine
- gold salts
- illicit drugs (heroin, methadone)
- rituximab, anti-TNF α agents (infliximab, etanercept, adalimumab)

Radiation-Induced
- early pneumonitis: approximately 6 wk post-exposure
- late fibrosis: 6-12 mo post-exposure
- infiltrates conform to the shape of the radiation field
Pulmonary Vascular Disease

Pulmonary Hypertension

Definition
• mean pulmonary arterial pressure >25 mmHg at rest and >30 mmHg with exercise, or a systolic pulmonary artery pressure of >40 mmHg at rest
• in the past, pulmonary HTN was classified as primary or secondary pulmonary HTN, but this classification was modified to a more clinically useful, treatment based classification (Table 19)

Adapted from Simonneau, et al. J Am Coll of Cardiol 2009

Mechanisms of Pulmonary Hypertension (simplified)
• hypoxic vasoconstriction
  ▪ chronic hypoxia causes pulmonary vasoconstriction by a variety of actions on the pulmonary artery endothelium and smooth muscle cells, such as: down regulation of endothelial nitric oxide synthase and alteration of voltage gated potassium channels leading to vasoconstriction
  ▪ causes: COPD, chronic alveolar hypoxia
• decreased area of pulmonary vascular bed
  ▪ leads to a rise in resting pulmonary arterial pressure
  ▪ causes: collagen vascular disease, HIV infection, drugs and toxins, thrombotic or embolic disease, inflammatory, pulmonary capillary hemangiomatosis, interstitial fibrosis, CF
• volume and pressure overload
  ▪ significant HTN only occurs with excessive volume overload, since pulmonary artery pressure will not rise in otherwise normal lung until pulmonary blood flow exceeds 2.5x the basal rate
  ▪ causes: congenital systemic to pulmonary shunts (e.g. VSD, ASD, PDA), portopulmonary HTN, left-sided heart conditions, pulmonary veno-occlusive disease, extrinsic compression of central pulmonary veins
IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION (aka PRIMARY PULMONARY HYPERTENSION)

Definition
- pulmonary HTN in the absence of a demonstrable cause
- exclude:
  - left-sided cardiac valvular disease
  - myocardial disease
  - congenital heart disease
  - any clinically significant parenchymal lung disease
  - systemic connective-tissue disease
  - chronic thromboembolic disease

Epidemiology
- usually presents in young women (20-40 yr); mean age of diagnosis is 36 yr
- most cases are sporadic; familial predisposition in 10% of cases, some linked to mutations in BMPR2
- may be associated with the use of anorexic drugs (e.g. Aminorex®, Fenfluramine*), also amphetamines and cocaine

Signs and Symptoms
- exertional dyspnea, fatigue, syncope, exertional chest pain, Raynaud's phenomenon
- see Table 20

Table 20. Signs and Symptoms of Pulmonary Hypertension

<table>
<thead>
<tr>
<th>Symptoms of underlying disease</th>
<th>Signs</th>
</tr>
</thead>
<tbody>
<tr>
<td>RV failure: right sided S$_2$, increased JVP, positive HJR, peripheral edema, TR</td>
<td></td>
</tr>
</tbody>
</table>

Investigations
- CXR: enlarged central pulmonary arteries, cardiac changes due to RV enlargement (filling of retrosternal air space)
- ECG
  - RVH/right-sided strain (see Cardiology and Cardiovascular Surgery, C7)
- 2-D echo doppler assessment of right ventricular systolic pressure
- cardiac catheterization: direct measurement of pulmonary artery pressures (necessary to confirm diagnosis)
- PFTs to assess for underlying lung disease: DL$_CO$ usually reduced
- CT angiogram to assess lung parenchyma and possible PE
- V/Q scan ± pulmonary angiogram to rule out thromboembolic disease
- serology: ANA positive in 30% of patients with primary pulmonary HTN. Other serologic markers can be used in the appropriate clinical setting

Treatment
- see Table 19

Prognosis
- 2-3 yr mean survival from time of diagnosis
- survival decreases to approximately 1 yr if severe pulmonary HTN or right-heart failure

Pulmonary Embolism (PE)

Definition
- lodging of a blood clot in the pulmonary arterial tree with subsequent increase in pulmonary vascular resistance, impaired V/Q matching, and possibly reduced pulmonary blood flow

Etiology and Pathophysiology
- one of the most common causes of preventable death in the hospital
- proximal leg thrombi (popliteal, femoral or iliac veins) are the source of most clinically recognized pulmonary emboli
- thrombi often start in calf, but must propagate into proximal veins to create a sufficiently large thrombus for a clinically significant PE
- fewer than 30% of patients have clinical evidence of DVT (e.g. leg swelling, pain or tenderness)
- always suspect PE if patient develops fever, sudden dyspnea, chest pain, or collapse 1-2 wk after surgery
**Risk Factors**
- **Stasis**
  - Immobilization: paralysis, stroke, bed rest, prolonged sitting during travel, immobilization of an extremity after fracture
  - Obesity, CHF
  - Chronic venous insufficiency
- **Endothelial cell damage**
  - Post-operative injury, trauma
- **Hypercoagulable states**
  - Underlying malignancy (particularly adenocarcinoma)
  - Cancer treatment (chemotherapy, hormonal)
  - Exogenous estrogen administration (OCP, HRT)
  - Pregnancy, post-partum
  - Prior history of DVT/PE, family history
  - Nephrotic syndrome
- **Coagulopathies**: Factor V Leiden, Prothrombin 20210A variant, inherited deficiencies of antithrombin/protein C/protein S, antiphospholipid antibody, hyperhomocysteinemia, increased Factor VIII levels, and myeloproliferative disease

- Increasing age

**Investigations** (if highly suspicious, go straight to spiral CT angiogram)
- **See Emergency Medicine, Figure 12, ER34**
- **Pulmonary Angiogram (Gold Standard)**
  - Filling defect indicative of embolus; negative angiogram excludes clinically relevant PE
  - More invasive, and harder to perform than CT, therefore done infrequently
- **D-dimer**
  - Products of thrombotic/fibrinolytic process
  - Highly sensitive D-dimer result can exclude DVT/PE if pretest probability is already low
  - Low value if pretest probability is high
- **CT angiogram**
  - Both sensitive and specific for PE
  - Diagnosis and management uncertain for small filling defects
  - Spiral CT may identify an alternative diagnosis if PE is not present
  - CT scanning of the proximal leg and pelvic veins can be done at the same time and may be helpful
- **Venous duplex U/S or Doppler**
  - With leg symptoms
  - Positive test rules in proximal DVT
  - Negative test rules out proximal DVT
  - Without leg symptoms
  - Positive test rules in proximal DVT
  - Negative test does not rule out a DVT; patient may have non-occlusive or calf DVT
- **ECG**
  - Findings not sensitive or specific
  - Sinus tachycardia most common; may see non-specific ST segment and T wave changes
  - RV strain, RAD, RBBB, S1-Q3-T3 with massive embolization
- **CXR**
  - Frequently normal; no specific features
  - Atelectasis (subsegmental), elevation of a hemidiaphragm
  - Pleural effusion: usually small
  - Hampton's hump: cone-shaped area of peripheral opacification representing infarction
  - Westermark's sign: dilated proximal pulmonary artery with distal oligemia/decreased vascular markings (difficult to assess without prior films)
  - Dilatation of proximal PA: rare
- **V/Q scan**
  - Very sensitive but low specificity
  - With order scan if
    - CXR normal, no COPD
    - Contraindication to CT (contrast allergy, renal dysfunction, pregnancy)
  - Avoid V/Q scan if
    - CXR abnormal or COPD
    - Inpatient
    - Suspect massive PE
  - Results: normal: excludes the diagnosis of PE
  - High probability: most likely means PE present, unless pre-test probability is low
  - 60% of V/Q scans are nondiagnostic
- **Echocardiogram**
  - Useful to assess massive or chronic PE
  - Not routinely done
- **ABG**
  - No diagnostic use in PE (insensitive and nonspecific)
  - May show respiratory alkalosis (due to hyperventilation)

---

**Clinical Prediction Rule for Pulmonary Embolism**
*J Thromb Hemost* 2000;8:416-420

<table>
<thead>
<tr>
<th>Risk Factors</th>
<th>Points</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clinical signs of DVT</td>
<td>3.0</td>
</tr>
<tr>
<td>No more likely alternative diagnosis</td>
<td>3.0</td>
</tr>
<tr>
<td>Immobilization or surgery in the previous 4 wk</td>
<td>1.5</td>
</tr>
<tr>
<td>Previous PE/DVT</td>
<td>1.5</td>
</tr>
<tr>
<td>HR &gt; 100 beats/min</td>
<td>1.5</td>
</tr>
<tr>
<td>Hemoptysis</td>
<td>1.0</td>
</tr>
<tr>
<td>Malignancy</td>
<td>1.0</td>
</tr>
</tbody>
</table>

**Clinical probability**
- Low (0-2): 3%
- Intermediate (3-6): 29%
- High (>6): 78%
- Modified Wells: >4 PE likely; <4 PE unlikely

---

**PE Rule-out Criteria (PERC)**
*Prospective Multicenter Evaluation of the Pulmonary Embolism Rule-out Criteria (PERC)*
*J Thromb Hemost* 2006;8:772

- Age less than 50 yr
- Heart rate less than 100 bpm
- Oxygenation saturation >95 percent
- No hemoptysis
- No estrogen use
- No prior DVT or PE
- No unilateral leg swelling
- No surgery or trauma requiring hospitalization within the past 4 wk

Acute PE can probably be excluded without further diagnostic testing if the patient meets all PERC criteria AND there is a low clinical suspicion for PE, according to either the Wells criteria or a low gestalt probability determined by the clinician prior to diagnostic testing for PE.

---

**Evaluation of a Suspected Pulmonary Embolism**

Low clinical probability of embolism:

<table>
<thead>
<tr>
<th>D-dimer (+ve)</th>
<th>CT scan (+ve)</th>
<th>ruled in</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-ve) ruled out</td>
<td>(-ve) ruled out</td>
<td></td>
</tr>
</tbody>
</table>

Intermediate or high probability:

<table>
<thead>
<tr>
<th>CT scan (+ve)</th>
<th>ruled out</th>
</tr>
</thead>
<tbody>
<tr>
<td>(+ve) ruled in</td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**
- Use D-dimers only if low clinical probability, otherwise, go straight to spiral CT
- If using V/Q scans (CT contrast allergy or renal failure):
  - Negative V/Q scan rules out the diagnosis
  - High probability V/Q scan only rules in the diagnosis if have high clinical suspicion
  - Inconclusive V/Q scan requires leg U/S to look for DVT or spiral CT

**Classic ECG finding of PE is S1-Q3-T3 (inverted T3), but most commonly see only sinus tachycardia.**

**D-dimer is elevated in patients with recent surgery, cancer, inflammation, infection, and severe renal dysfunction.**

It has good sensitivity and negative predictive value, but poor specificity and positive predictive value.
### Treatment
- admit for observation (patients with DVT only are often sent home on LMWH)
- oxygen: supplemental O<sub>2</sub> if hypoxemic or short of breath
- pain relief: analgesics if chest pain – narcotics or acetaminophen
- acute anticoagulation: therapeutic-dose SC LMWH or IV heparin – start ASAP
  - anticoagulation stops clot propagation, prevents new clots and allows endogenous fibrinolytic system to dissolve existing thromboemboli over months
  - get baseline CBC, INR, aPTT ± liver function
  - for SC LMWH: dalteparin 200 U/kg once daily or enoxaparin 1 mg/kg bid – no lab monitoring – avoid or reduce dose in renal dysfunction
  - for IV heparin: bolus of 75 U/kg (usually 5,000 U) followed by infusion starting at 20 U/kg/h – aim for aPTT 2-3x control
- long term anticoagulation
  - warfarin: start the same day as LMWH/heparin – overlap warfarin with LMWH/heparin for at least 5 d and until INR in target range of 2-3 for at least 2 d
  - LMWH instead of warfarin for pregnancy, active cancer, or high bleeding risk patients
  - dabigatran has been shown to have lower bleeding risk than warfarin
  - IV thrombolytic therapy
  - if patient has massive PE (hypotension or clinical right heart failure) and no contraindications
  - hastens resolution of PE but may not improve survival or long-term outcome and doubles risk of major bleeding
  - interventional thrombolytic therapy
  - massive PE is preferentially treated with catheter-directed thrombolysis by an interventional radiologist
  - works better than IV thrombolytic therapy and fewer contraindications
  - IVC filter: only if recent proximal DVT + absolute contraindication to anticoagulation
  - duration of long-term anticoagulation: individualized, however generally:
    - if reversible cause for PE (surgery, injury, pregnancy, etc.): 3-6 mo
    - if PE unprovoked: 6 mo to indefinite
    - if ongoing major risk factor (active cancer, antiphospholipid antibody, etc.): indefinite

### Thromboprophylaxis
- mandatory for most hospital patients: reduces DVT, PE, all-cause mortality, cost-effective
- start ASAP
- continue at least until discharge or recommend extending for 35 d postoperatively, if major orthopedic surgery

### Workup for Idiopathic VTE
#### Thrombophilia Workup: recurrent or idiopathic DVT/PE: age > 50, FHx, unusual location, massive.

#### Malignancy Workup: 12% of patients with idiopathic VTE will have a malignancy.

### Extended Use of Dabigatran, Warfarin or Placebo in Venous Thromboembolism
NEJM 2013;369:709-718
- Study: Two double blind, RCTs; one comparing against placebo, the other against active treatment
- Population: 4,119 patients (2,856 in active-control study, 1,343 in placebo-control study) with VTE who had completed at least 3 mo of therapy
  - Intervention: In the active-control study, patients randomized to either 150 mg dabigatran or warfarin (INR 2.0-3.0). Patients in the placebo-control study received either 150 mg dabigatran or placebo.
- Outcome: Recurrence of VTE, risk of major or clinically relevant bleed.
  - Results: In the active-control study, there was a hazard ratio (HR) of 1.44 (95%, 0.78-2.64 for non-inferiority) of recurrent VTE with dabigatran vs. warfarin. HR of major or clinically relevant bleed was 0.95 (95%, 0.41-2.11). In the placebo-control study, the HR of VTE with dabigatran vs. placebo was 0.03 (95%, 0.00-0.25). HR of major or clinically relevant bleed was 2.92 (95%, 1.52-5.60).
  - Conclusions: Dabigatran appears to be non-inferior to warfarin in the prevention of VTE recurrence. Dabigatran is associated with a lower risk of major or clinically relevant bleed than warfarin, but greater than placebo.

### Excluding Pulmonary Embolism at Bedside without Diagnostic Imaging
- Study: Multicentre, prospective cohort study.
  - Patients: 930 patients with suspected PE at emergency departments at 4 tertiary care hospitals in Canada.
  - Intervention: A Wells score was used to determine patient’s pretest probability (PTP) of PE along with a D-dimer test was performed. Patients with low PTP and a negative D-dimer test had no further testing and the diagnosis of PE was excluded. All other patients had V/Q scanning, and if non-diagnostic, had bilateral deep venous ultrasonography. Further serial ultrasonography and angiography were done depending on the patients’ PTP and lung scanning results.
  - Main outcomes: Diagnosis of PE and the development of thromboembolic events at 3 mo follow-up.
  - Results: One of 798 patients in whom PE was initially ruled out developed a thromboembolic event during follow-up (0.1% [0.07%-0.2%]). One of the 437 patients with negative D-dimers and low clinical PTP developed PE during follow up (MPV 99.3, CI 99.1-100%).
  - Conclusion: Managing patients with suspected pulmonary embolism on the basis of PTP and D-dimer result is safe and decreases the need for diagnostic imaging.

### Pulmonary Edema

- see [Cardiology and Cardiovascular Surgery, C32](#)

### Diseases of the Mediastinum and Pleura

#### Mediastinal Masses

**Definition**
- mediastinum: bound by the thoracic inlet, diaphragm, sternum, vertebral bodies and the pleura
- can be broken down into 3 compartments: anterior, middle and posterior (see sidebar)

**Etiology and Pathophysiology**
- diagnosis is made by location and patient’s age
- anterior compartment: more likely to be malignant
  - “Five Ts” (see sidebar), lymphoma, lipoma, pericardial cyst
- middle compartment
  - pericardial cyst, bronchogenic cyst/tumour, lymphoma, lymph node enlargement, aortic aneurysm
- posterior compartment
  - neurogenic tumours, meningocele, enteric cysts, lymphoma, diaphragmatic hernias, esophageal tumour, aortic aneurysm

**Signs and Symptoms**
- 50% asymptomatic (mainly benign); when symptomatic, 50% are malignant
- chest pain, cough, dyspnea, recurrent respiratory infections
- hoarseness, dysphagia, Horner’s syndrome, facial/upper extremity edema (SVC compression)
- paraneoplastic syndromes [e.g. myasthenia gravis (thymomas)]

**Investigations**
- CXR (compare to previous)
- CT with contrast (anatomic location, density, relation to mediastinal vascular structures)
- MRI: specifically indicated in the evaluation of neurogenic tumours
- U/S (best for assessment of structures in close proximity to the heart and pericardium)
- radionuclide scanning: 123I (for thyroid), gallium (for lymphoma)
- biochemical studies: thyroid function, serum calcium, phosphate, PTH, AFP, β-hCG
- biopsy (mediastinoscopy, percutaneous needle aspiration)
Management

- excision if symptomatic enlarging benign masses or concerns of malignancy
- resect bronchogenic cysts and localized neurogenic tumours via minimally invasive video assisted procedures
- exploration via sternotomy or thoracotomy
- diagnostic biopsy rather than major operation if mass is likely to be a lymphoma, germ cell tumour, or unresectable invasive malignancy
- ± post-op radiotherapy/chemotherapy if malignant

Mediastinitis

- commonest causes: postoperative complications of cardiovascular or thoracic surgical procedures

Acute

- etiology
  - complication of endoscopy (e.g. esophageal perforation providing entry point for infection)
  - esophageal or cardiac surgery
  - tumour necrosis
- signs and symptoms
  - fever, substernal pain
  - pneumomediastinum, mediastinal compression
  - Hamman’s sign (auscultatory “crunch” during cardiac systole)
- treatment
  - antibiotics, drainage, ± surgical closure of perforation

Chronic

- usually granulomatous process or fibrosis related to previous infection (e.g. histoplasmosis, TB, sarcoidosis, syphilis)

Pleural Effusions

Definition

- excess amount of fluid in the pleural space (normally up to 25 mL)

Etiology

- disruption of normal equilibrium between pleural fluid formation/entry and pleural fluid absorption/exit
- pleural effusions are classified as transudative or exudative
  - distinguish clinically using Light’s Criteria (Table 23), which has a sensitivity of 98% and specificity of 83% for identifying exudative pleural effusions

<table>
<thead>
<tr>
<th>Light’s Criteria</th>
<th>Modified Light’s Criteria</th>
</tr>

<tr>
<td>LDH – pleural/serum</td>
<td>&gt;0.6</td>
</tr>
<tr>
<td>Pleural LDH</td>
<td>&gt;2/3 upper limit of N serum LDH</td>
</tr>
</tbody>
</table>

Transudative Pleural Effusions

- pathophysiology: alteration of systemic factors that affect the formation and absorption of pleural fluid (e.g. increased capillary hydrostatic pressure, decreased plasma oncotic pressure)
- etiology
  - CHF: usually right-sided or bilateral cirrhosis
  - nephrotic syndrome, protein losing enteropathy, cirrhosis
  - pulmonary embolism (may cause transudative but more often causes exudative effusion)
  - peritoneal dialysis, hypothyroidism, CF, urinothorax

Exudative Pleural Effusions

- pathophysiology: increased permeability of pleural capillaries or lymphatic dysfunction
- etiology (see Table 24)
Table 24. Exudative Pleural Effusion Etiologies

<table>

</tr>
<tr>
<td></td>
<td>Hemorrhage: rupture of a blood vessel, commonly by trauma or tumours</td>
</tr>
<tr>
<td></td>
<td>Pneumothorax (spontaneous, traumatic, tension)</td>
</tr>
</tbody>
</table>

Signs and Symptoms
- often asymptomatic
- dyspnea: varies with size of effusion and underlying lung function
- pleuritic chest pain
- inspection: trachea deviates away from effusion, ipsilateral decreased expansion
- percussion: decreased tactile fremitus, dullness
- auscultation: decreased breath sounds, bronchial breathing and egophony at upper level, pleural friction rub

Investigations
- CXR
  - must have >200 mL of pleural fluid for visualization on PA film
  - lateral: >50 mL leads to blunting of posterior costophrenic angle
  - PA: blunting of lateral costophrenic angle
  - dense opacification of lung fields with concave meniscus
  - decubitus: fluid will shift unless it is loculated
  - supine: fluid will appear as general haziness
- thoracentesis: indicated if pleural effusion is a new finding; be sure to send off blood work (LDH, glucose, protein) at the same time for comparison
  - risk of re-expansion pulmonary edema if >1.5 L of fluid is removed
  - inspect for colour, character, and odour of fluid
  - analyze fluid (see Tables 23 and 25)
- pleural biopsy: indicated if suspect TB, mesothelioma, or other malignancy (and if cytology negative)
- ± U&S: detects small effusions and can guide thoracentesis
- treatment depends on cause, ± drainage if symptomatic
- CT can be helpful in differentiating parenchymal from pleural abnormalities

Treatment
• thoracentesis
• treat underlying cause
• consider indwelling pleural catheter or pleurodesis in refractory effusions

Complicated Parapneumonic Effusion
• persistent bacteria in the pleural space, but fluid is non-purulent
• neutrophils, pleural fluid acidosis (pH <7.00), and high LDH
• often no bacteria grown, since rapidly cleared from pleural space
• fibrin layer leading to loculation of pleural fluid
• treatment: antibiotics and drainage, treat as an empyema

Empyema
Definition
• pus in pleural space or an effusion with organisms seen on a Gram stain or culture (i.e. pleural fluid is grossly purulent)
• positive culture is not required for diagnosis

Etiology
• contiguous spread from lung infection (most commonly anaerobes), or infection through chest wall (e.g. trauma, surgery)

Signs and Symptoms
• fever, pleuritic chest pain

Investigations
• CT chest
• thoracentesis
• PMNs (lymphocytes in TB) ± visible organisms on Gram stain

Treatment
• antibiotic therapy for at least 4-6 wk (rarely effective alone)
• complete pleural drainage with chest tube
• if loculated, more difficult to drain – may require surgical drainage video-assisted thorascopic surgery (VATS)

Atelectasis
• see General Surgery, GS10

Pneumothorax
Definition
• presence of air in the pleural space

Pathophysiology
• increased intrapleural pressure reduces lung inflation

Etiology
• traumatic: penetrating or non-penetrating chest injuries
• iatrogenic (central venous catheter, thoracentesis, mechanical ventilation with barotrauma)
• spontaneous (no history of trauma)
  • primary (no underlying lung disease)
    • spontaneous rupture of apical subpleural bleb of lung into pleural space
    • predominantly tall, healthy, young males
  • secondary (underlying lung disease)
    • rupture of subpleural bleb which migrates along bronchialveolar sheath to the mediastinum then to the intrapleural space
    • necrosis of lung tissue adjacent to pleural surface (e.g. pneumonia, abscess, PCP, lung CA, emphysema)

Signs and Symptoms
• can be asymptomatic
• acute-onset pleuritic chest pain, dyspnea
• tachypnea, tachycardia

Pleural Effusions
Simple Effusion
pH >7.2, LDH <1/2 serum, glucose >2.2

Complicated Effusion
pH <7.2, LDH >1/2 serum, glucose <2.2, positive Gram stain
Needs drainage

When possible, organism-directed therapy, guided by culture sensitivities or local patterns of drug resistance, should be utilized.

Need to Rule Out Life-Threatening Tension Pneumothorax
If pneumothorax with:
• Severe respiratory distress
• Tracheal deviation to contralateral side
• Distended neck veins († JVP)
• Hypotension
Do not perform CXR.
See Emergency Medicine, ER11
• tracheal deviation (contralateral deviation in tension pneumothorax)
• ipsilateral diminished chest expansion
• decreased tactile/vocal fremitus
• hyperresonance
• ipsilateral diminished breath sounds

Investigations
• CXR
  ▪ small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  ▪ large: increased density and decreased volume of lung on side of pneumothorax
  ▪ see Medical Imaging, M18

Treatment
• small pneumothoraces (<20% with no signs of respiratory/circulatory collapse) resolve spontaneously; breathing 100% oxygen accelerates resorption of air
• small intercostal tube with Heimlich valve for most spontaneous pneumothoraces
• large pneumothoraces or those complicating underlying lung disease require placement of a chest tube connected to underwater seal ± suction
• for repeated episodes: pleurodesis with sclerosing agent or apical bullectomy and abrasion
• treat underlying cause (e.g. antibiotic for PCP)

Asbestos-Related Pleural Disease and Mesothelioma

Etiology and Pathophysiology
• benign manifestations of asbestos exposure
  ▪ "benign asbestos pleural effusion"
    ▪ exudative effusion, typically ≈10 yr after exposure, resolves
  ▪ pleural plaques, usually calcified
    ▪ marker of exposure; usually an asymptomatic radiologic finding
• mesothelioma
  ▪ primary malignancy of the pleura
  ▪ decades after asbestos exposure (even with limited exposure)
  ▪ smoking not a risk factor, but asbestos and smoking synergistically increase risk of lung cancer

Signs and Symptoms
• persistent chest pain, dyspnea, cough, bloody pleural effusion, weight loss

Investigations
• biopsy (pleuroscopic or open)
• needle biopsy may seed needle tract with tumour

Treatment
• resection (extrapleural pneumonectomy) requires careful patient selection; rarely successful (average survival <1 yr)

Respiratory Failure

Definition
• failure of respiratory system to maintain normal blood gases
• hypoxemic ($P_{aO2} <60$ mmHg)
• hypercapnic ($P_{aCO2} >50$ mmHg)
• acute vs. chronic (compensatory mechanisms activated)

Signs and Symptoms
• signs of underlying disease
• hypoxemia: restlessness, confusion, cyanosis, coma, cor pulmonale
• hypercapnia: headache, dyspnea, drowsiness, asterixis, warm periphery, plethora, increased ICP (secondary to vasodilatation)

Investigations
• serial ABGs
• CXR and/or CT, bronchoscopy to characterize underlying cause if unclear
**Hypoxemic Respiratory Failure**

**Definition**
- $P_aO_2$ decreased, $P_aCO_2$ normal or decreased

**Treatment**
- reverse the underlying pathology
- oxygen therapy: maintain oxygenation (if shunt present, supplemental $O_2$ is less effective; see Anesthesia, A10, for oxygen delivery systems)
- ventilation, BiPAP and PEEP/CPAP (see Mechanical Ventilation, R26): positive pressure can recruit alveoli and redistribute lung fluid
- improve cardiac output: ± hemodynamic support (fluids, vasopressors, inotropes), reduction of $O_2$ requirements

</tbody>
</table>

Reprinted with permission from Dr. Ian Fraser

**Hypercapnic Respiratory Failure**

- $P_aCO_2$ increased, $P_aO_2$ decreased

**Pathophysiology**
- increased $CO_2$ production: fever, sepsis, seizure, acidosis, carbohydrate load
- alveolar hypoventilation: COPD, asthma, CF, chest wall disorder, dead space ventilation (rapid shallow breathing)
  - i.e. inefficient gas exchange results in inadequate $CO_2$ removal in spite of normal or increased minute volume
- hyperventilation
  - central: brainstem stroke, hypothyroidism, severe metabolic alkalosis, drugs (opiates, benzodiazepines)
  - neuromuscular: myasthenia gravis, Guillain-Barré, phrenic nerve injury, muscular dystrophy, polymyositis, kyphoscoliosis
  - muscle fatigue

**Treatment**
- reverse the underlying pathology
- if $P_aCO_2 > 50$ mmHg and pH is acidemic consider noninvasive or mechanical ventilation
- correct exacerbating factors
  - NTT/ETT suction: clearance of secretions
  - bronchodilators: reduction of airway resistance
  - antibiotics: treatment of infections
- maintain oxygenation (see above)
- diet: increased carbohydrate can increase $P_aCO_2$ in those with mechanical or limited alveolar ventilation; high lipids decrease $P_aCO_2$
Acute Respiratory Distress Syndrome (ARDS)

- clinical syndrome characterized by severe respiratory distress, hypoxemia, and noncardiogenic pulmonary edema
- The Berlin Criteria (JAMA 2012; 307:2526-2533) for ARDS:
  - acute onset
    - within 7 d of a defined event, such as sepsis, pneumonia, or patient noticing worsening of respiratory symptoms
    - usually occurs within 72 h of presumed trigger
  - bilateral opacities consistent with pulmonary edema on either CT or CXR
  - not fully explained by cardiac failure/fluid overload, but patient may have concurrent heart failure
  - an objective assessment (e.g. echocardiogram) should be performed if no clear risk factors

Etiology

- direct lung injury:
  - airway: aspiration (gastric contents, drowning), pneumonia, inhalation injury (oxygen toxicity, nitrogen dioxide, smoke)
  - circulation: embolism (fat, amniotic fluid), reperfusion injury
- indirect lung injury
  - circulation: sepsis, shock, trauma, blood transfusion, pancreatitis
  - neurogenic: head trauma, intracranial hemorrhage, drug overdose (narcotics, sedatives, TCAs)

Pathophysiology

- disruption of alveolar capillary membranes → leaky capillaries → interstitial and alveolar pulmonary edema → reduced compliance, V/Q mismatch, shunt, hypoxemia, pulmonary HTN

Clinical Course

A. Exudative Phase
- first 7 d of illness after exposure to ARDS precipitant
- alveolar capillary endothelial cells and type I pneumocytes are injured, resulting in loss of normally tight alveolar barrier
- patients develop dyspnea, tachypnea, increased work of breathing
  - these result in respiratory fatigue and eventually respiratory failure (see Hypoxic Respiratory Failure, R25)

B. Fibroproliferative Phase
- after day 7
- may still experience dyspnea, tachypnea, fatigue, and hypoxemia
- most patients clinically improve and are able to wean off mechanical ventilation
- some patients develop fibrotic lung changes that may require long-term support on supplemental oxygen or even mechanical ventilation
- if fibrosis present, associated with increased mortality

Treatment

- based on ARDS network (see Landmark Respiratory Trials, R35)
- treat underlying disorder (e.g. antibiotics if infection present)
- mechanical ventilation using low tidal volumes (<6 mL/kg) to prevent barotrauma
  - use optimal amount of PEEP (positive end-expiratory pressure) to keep airways open and allow the use of lower $P_{O_2}$
  - may consider using prone ventilation, and/or inhaled nitric oxide, high frequency oscillator or ECMO (extracorporeal membrane oxygenation) if conventional treatment is failing
- fluids and inotropic therapy (e.g. dopamine, vasopressin) if cardiac output inadequate
- pulmonary-arterial catheter now seldom used for monitoring hemodynamics
- mortality: 30-40%, usually due to non-pulmonary complications
- sequelae of ARDS include residual pulmonary impairment, severe debilitation, polynuropathy and psychologic difficulties, which gradually improve over time
- most survivors eventually regain near-normal lung function, often with mildly reduced diffusion capacity

Mechanical Ventilation

- see Anesthesia, A10

Definition

- artificial means of supporting ventilation and oxygenation
- mechanically ventilated patients may require some sedation and/or analgesia

</tbody>
</table>

ALI versus ARDS: Definition is the same, except ALI is a $P_{O_2}/FiO_2 \leq 300$, while ARDS is a $P_{O_2}/FiO_2 \leq 200$
Indications
- general indications
  - hypoxic respiratory failure
  - hypercapnic respiratory failure
- specific indicators for mechanical ventilation
  - acute ventilation failure/acute respiratory acidosis
  - refractory hypoxemia
  - reduced level of consciousness
  - facilitation of surgical procedures

Ventilator Strategies
- mode and settings are determined based on patient factors (e.g., ideal body weight, compliance, resistance) and underlying reason for mechanical ventilation
- hypoxic respiratory failure: ventilator provides supplemental oxygen, recruits atelectatic lung segments, helps improve V/Q mismatch, and decreases intrapulmonary shunt
- hypercapnic respiratory failure: ventilator augments alveolar ventilation; may decrease the work of breathing, allowing respiratory muscles to rest

Modes of Ventilation
- assist-control ventilation (ACV)
  - every breath is delivered with a pre-set tidal volume and rate or minute ventilation
  - extra controlled breaths may be triggered by patient effort; if no effort is detected within a specified amount of time the ventilator will initiate the breath
- pressure control ventilation (PCV)
  - a minimum frequency is set and patient may trigger additional breaths above the ventilator
  - all breaths delivered at a preset constant inspiratory pressure
- synchronous intermittent mandatory ventilation (SIMV)
  - ventilator provides controlled breaths (either at a set volume or pressure)
  - patient can breathe spontaneously (these breaths may be pressure supported) between controlled breaths
- pressure support ventilation (PSV)
  - patient initiates all breaths and the ventilator supports each breath with a pre-set inspiratory pressure
  - useful for weaning off ventilator
- high-frequency oscillatory ventilation (HFOV)
  - very high breathing rate (up to 900 breaths/min in an adult), very low tidal volumes
  - used commonly in neonatal and pediatric respiratory failure
  - used in adults when conventional mechanical ventilation is failing.
- noninvasive positive pressure ventilation (NPPV)
  - achieved without intubation by using a nasal or face mask with:
    - BiPAP: increased pressure (like PSV) on inspiration and lower constant pressure on expiration
    - CPAP: delivers constant pressure on both inspiration and expiration

Complications of Mechanical Ventilation
- airway complications
  - tracheal stenosis, laryngeal edema
- alveolar complications
  - ventilator-induced lung injury, ventilator-associated pneumonia (nosocomial pneumonia), barotrauma, volutrauma, inflammation, auto-PEEP, patient-ventilator asynchrony
- cardiovascular complications
  - reduced venous return, reduced cardiac output, hypotension
- neuromuscular complications
  - muscle atrophy
  - increased intracranial pressure

Monitoring Ventilatory Therapy
- used with all invasive modes of ventilation

A Comparison of Four Methods of Weaning Patients from Mechanical Ventilation

Study: Prospective, randomized, multicenter trial.
Participants: 130 of 546 patients who received mechanical ventilation and were considered ready for weaning but had respiratory distress during a 2 h trial of spontaneous breathing.
Intervention: One of four weaning techniques following standardized protocol.
Outcome: Median duration of weaning.
Results: The median duration of weaning for intermittent mandatory ventilation, pressure-support ventilation, intermittent (multiple) trials of spontaneous breathing, and once-daily trial of spontaneous breathing was 5.4, 4.4, and 3.0 days respectively. The rate of successful weaning was higher with once-daily trial of spontaneous breathing than with intermittent mandatory ventilation (rate ratio 2.83; 95% CI 1.36 to 5.89; p<0.006) or pressure-support ventilation (rate ratio 2.05; 95% CI 1.04 to 4.04; p<0.04). There was no significant difference in the rate of success between once-daily trials and multiple trials of spontaneous breathing.
Conclusions: Once-daily or multiple trials of spontaneous breathing led to extubation more quickly than intermittent mandatory or pressure-support ventilation.

Tracheostomy
- Tracheostomy should be considered in patients who require ventilator support for extended periods of time
- Shown to improve patient comfort and give patients a better ability to participate in rehabilitation activities

Positive End Expiratory Pressure (PEEP)
- Positive pressure applied at the end of ventilation which opens up collapsed alveoli decreasing V/Q mismatch
- Used with all invasive modes of ventilation

Management of pneumothorax in patients on mechanical ventilation → chest tube.

Neoplasms

Lung Cancer

Classification
- lung tumours can be classified as primary or secondary, benign or malignant, endobronchial or parenchymal
- bronchogenic carcinoma (epithelial lung tumours) are the most common type of primary lung tumour (other types make up less than 1%)
  - small cell lung cancer (SCLC)
  - non-small-cell lung cancer (NSCLC)
    - squamous cell carcinoma: arise from the proximal respiratory epithelium
    - bronchioalveolar carcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring
    - large cell undifferentiated cancer: diagnosis of exclusion
- benign epithelial lung tumours can be classified as papillomas or adenomas

### Risk Factors
- cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers
- other risk factors include cigar smoking, pipe smoking, second-hand smoke, asbestos without smoking (relative risk is 5), asbestos with smoking (relative risk is 92), metals (e.g. chromium, arsenic, nickel), radon gas, ionizing radiation, genetics

### Signs and Symptoms
- may be due to primary lesion, metastasis, or paraneoplastic syndrome
  - primary lesion:
    - cough (75%): beware of chronic cough that changes in character
    - dyspnea (60%)
    - chest pain (45%)
    - hemoptysis (35%)
    - other pain (25%)
    - clubbing (21%)
    - constitutional symptoms: anorexia, weight loss, fever, anaemia
  - metastasis
    - lung, hilum, mediastinum, pleura: pleural effusion, atelectasis, wheezing
    - pericardium: pericarditis, pericardial tamponade
    - esophageal compression: dysphagia
    - phrenic nerve: paralyzed diaphragm
    - recurrent laryngeal nerve: hoarseness
    - superior vena cava syndrome:
      - obstruction of SVC causing neck and facial swelling, as well as dyspnea and cough
      - other symptoms: hoarseness, tongue swelling, epistaxis, and hemoptysis
      - physical findings: dilated neck veins, increased number of collateral veins covering the anterior chest wall, cyanosis, edema of the face, arms, and chest, Pemberton's sign (facial flushing, cyanosis, and distension of neck veins upon raising both arms above head)
    - milder symptoms if obstruction is above the azygos vein
    - lung apex (Pancoast tumour): Horner's syndrome, brachial plexus palsy (most commonly C8 and T1 nerve roots)
    - rib and vertebral: erosion
    - distant metastasis to brain, bone, liver, adrenal
  - paraneoplastic syndromes (see Table 28)
    - a group of disorders associated with malignant disease, not related to the physical effects of the tumour itself
    - most often associated with SCLC

**Conclusions**: Screening with low-dose CT reduces mortality from lung cancer.

### Summary of Recommendations on Screening for Lung Cancer

- **Canadian Task Force on Preventive Health Care (2003)**
  - Screening with CXR: Not recommended
  - Screening with low-dose CT: Insufficient evidence to make recommendation
- **American College of Chest Physicians (2013)**
  - Screening with CXR: Not recommended
  - Screening with low-dose CT: Recommended for high-risk patients (current or former smokers quit within last 15 y, aged 55-74, ≥30 pack-yr smoking Hx)
- **American Lung Association (2013)**
  - Screening with CXR: Not recommended
  - Screening with low-dose CT: Recommended for high-risk patients (current or former smokers aged 55-74, ≥30 pack-yr smoking Hx, no Hx of lung cancer)

### Reduced Lung-cancer Mortality with Low-dose CT Screening

- Rate of positive screening test: 24.2% vs 6.9%
- False positives: 96.4% vs 94.5%
- Incidence of lung cancer: 645/100K vs 572/100K
- Deaths from lung cancer: 247/100K vs 308/100K

**Conclusions**: Screening with low-dose CT reduces mortality from lung cancer.

**Malignant lung tumours are the most common cause of cancer mortality throughout the world in both men and women.**

### Endobronchial Ultrasound (EBUS):
- Allows visualization of peri-bronchial structures and distal peripheral lung lesions
- Provides detailed assessment of the airway wall layers
- Allows for guided biopsies of lymph nodes and tumours
- Used for diagnosis and staging
Investigations

- initial diagnosis
  - imaging: CXR, CT chest + upper abdomen, PET scan, bone scan
  - cytology: sputum
  - biopsy: bronchoscopy, percutaneous mediastinoscopy

- staging work-up
  - TMN staging system: T – primary tumour (size); N – regional lymph nodes; M – distant metastasis
  - blood work: electrolytes, LFTs, calcium, ALP
  - imaging: CXR, CT thorax and upper abdomen, bone scan, neuroimaging
  - invasive: bronchoscopy (EBUS), mediastinoscopy, mediastinotomy, thoracotomy

</table>

* Depends on clinical vs. pathologic stage

Refer to AJCC Cancer Staging Manual, 7th ed. (2010) for complete TNM classification

Treatment

- options include surgery, radiotherapy, chemotherapy, and palliative care for end-stage disease (see Table 29)
- surgery not usually performed for SCLC since it is generally non-curable
- contraindications for surgery:
  - spread to contralateral lymph nodes or distant sites
  - patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases
  - poor pulmonary status (e.g. unable to tolerate resection of lung)
- chemotherapy (used in combination with other treatments)
  - common agents: etoposide, platinum agents (e.g. cisplatin), ifosfamide, vincristine, anthracyclines, paclitaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
  - complications:
    - acute: tumour lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
    - chronic: neurologic damage, leukemia, additional primary neoplasms

Prognosis

- 5 yr survival rates for different subtypes:
  - squamous cell carcinoma 25%
  - adenocarcinoma 12% (60% for bronchoalveolar carcinoma, a subtype of adenocarcinoma, with a resectable solitary lesion)
  - large cell carcinoma 13%
  - SCLC 1% (poorest prognosis)
  - NSCLC (see Table 29)

Prevention

- smoking cessation
- avoidance of exposures
- early detection
Approach to the Solitary Pulmonary Nodule

- also see Medical Imaging, MI7

Definition
- a round or oval, sharply circumscribed radiographic lesion up to 3-4 cm, which may or may not be calcified, and is surrounded by normal lung
- can be benign or malignant

Table 30. Differential Diagnosis for Benign vs. Malignant Solitary Nodule

Investigations (see Figure 11)
- CXR: always compare with previous CXR (see Table 31)
- CT densitometry and contrast enhanced CT of thorax
- sputum cytology: usually poor yield
- biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy or thoracotomy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  - if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  - if a biopsy is non-diagnostic, whether to observe, re-biopsy or resect will depend on the level of suspicion
- watchful waiting: repeat CXR and/or CT scan at 3, 6, 12 mo
- PET scan can help distinguish benign from malignant nodules

Sleep-Related Breathing Disorders

Hypoventilation Syndromes

- primary alveolar hypoventilation: idiopathic
- obesity-hypoventilation syndrome (Pickwickian syndrome)
- respiratory neuromuscular disorders

Sleep Apnea

Definition
- episodic decreases in airflow during sleep
- quantitatively measured by the Apnea/Hypopnea Index (AHI) = # of apneic and hypopneic events per hour of sleep
- sleep apnea generally accepted to be present if AHI >15

Classification
- obstructive (OSA)
  - caused by transient, episodic obstruction of the upper airway
  - absent or reduced airflow despite persistent respiratory effort
- central (CSA) (see Neurology, N42)
  - caused by transient, episodic decreases in CNS drive to breathe
  - no airflow because no respiratory effort
  - Cheyne-Stokes Respiration: a form of CSA in which central apneas alternate with hyperpneas to produce a crescendo-decrescendo pattern of tidal volume; seen in severe LV dysfunction, brain injury, and other settings (Figure 2)
- mixed (MSA)
  - features of both OSA and CSA
  - loss of hypoxic and hypercapnic drives to breathe secondary to "resuscitative breathing": overcompensatory hyperventilation upon awakening from OSA induced hypoxia

Risk Factors
- for OSA: obesity, upper airway abnormality, neuromuscular disease, hypothyroidism, alcohol/sedative use, nasal congestion, sleep deprivation
- for CSA: LV failure, brainstem lesions, encephalitis, encephalopathy, myxedema, high altitude

Signs and Symptoms
- obtain history from spouse/partner
- secondary to repeated arousals and fragmentation of sleep: daytime somnolence, personality and cognitive changes, snoring
- secondary to hypoxemia and hypercapnia: morning headache, polycythemia, pulmonary/systemic HTN, cor pulmonale/CHF, nocturnal angina, arrhythmias
- the typical presentation for OSA is a middle-aged obese male who snores
- CSA can be due to neurological disease

Investigations
- sleep study (polysomnography)
  - evaluates sleep stages, airflow, ribcage movement, ECG, SaO2, limb movements
  - indications
    - excessive daytime sleepiness
    - unexplained pulmonary HTN or polycythemia
    - daytime hypercapnia
    - titration of optimal nasal CPAP
    - assessment of objective response to other interventions

Treatment
- modifiable factors: weight loss, decreased alcohol/sedatives, nasal decongestion, treatment of underlying medical conditions
- OSA or MSA: nasal CPAP, postural therapy (i.e. no supine sleeping), dental appliance, uvulopalatopharyngoplasty, tonsillectomy
- CSA or hypoventilation syndromes: nasal BiPAP/CPAP, respiratory stimulants (e.g. progesterone) in select cases
- tracheostomy rarely required and should be used as last resort for OSA

Complications
- depression, weight gain, decreased quality of life, workplace and vehicular accidents, cardiac complications (e.g. HTN), reduced work/social function
Introduction to Intensive Care

• goal is to provide stabilization for critically ill patients: hemodynamic, respiratory or cardiac instability, or need for close monitoring

ICU Basics

Lines and Catheters

• arterial lines
  • monitor beat-to-beat blood pressure variations, obtain blood for routine ABGs
  • common sites are the radial and femoral arteries

• central venous catheter (central line)
  • administer IV fluids, monitor CVP, insert pulmonary artery catheters
  • administer TPN and agents too irritating for peripheral line
  • common sites: internal jugular vein, subclavian vein, femoral vein

• pulmonary arterial catheter
  • balloon guides the catheter from a major vein to the right heart
  • measures pulmonary capillary wedge pressure (PCWP) via a catheter wedged in distal pulmonary artery
  • PCWP reflects the LA and LV diastolic pressure (barring pulmonary venous or mitral valve disease)

• indications (N.B. now used infrequently due to associated complications):
  • diagnosis of shock states, primary pulmonary HTN, valvular disease, intracardiac shunts, cardiac tamponade, PE
  • assessment of hemodynamic response to therapies
  • differentiation of high- versus low-pressure pulmonary edema
  • management of complicated MI, multiorgan system failure and/or severe burns, or hemodynamic instability after cardiac surgery

• absolute contraindications:
  • tricuspid or pulmonary valve mechanical prosthesis
  • right heart mass (thrombus or tumour)
  • tricuspid or pulmonary valve endocarditis

ICU Psychosis

A form of delirium or acute brain failure that occurs in ICU patients. Signs and symptoms may include anxiety, agitation, paranoia, hallucinations, and disorientation in time and place. Treatment varies with cause.

Intensive Insulin Therapy in Critically Ill Patients

NEJM 2001;345:1359-1367

Study: Prospective, randomized controlled clinical outcome study.

Patients: 1548 patients admitted to the ICU.

Intervention: At admission, patients were randomly assigned to either intensive insulin therapy or conventional therapy. Those in the intensive group had an infusion started if BG exceeded 6.1 mmol/L, and maintained to keep BG between 4.4 to 6.1 mmol/L. Those in the conventional group were started on insulin only if BG exceeded 11.9, and the infusion was adjusted for a target between 10.0 and 11.1 mmol/L.

Primary Outcome: Death from any cause during ICU stay.

Results: 35 patients (4.6%) died in the intensive group in the ICU, versus 63 patients (8.0%) in the conventional group. This represents a 32% mortality reduction (p<0.04). Intensive insulin therapy also reduced overall in-hospital mortality, lowered deaths due to sepsis, multi-organ failure. Most of the mortality benefit was seen in long stay patients (</>5 d).

Conclusion: Intensive insulin therapy in the ICU reduces mortality by 32%, and improves in-hospital mortality and morbidity.
Shock

- see Emergency Medicine, ER3
- inadequate tissue perfusion potentially resulting in end organ injury
  - categories of shock:
    - hypovolemic: hemorrhage, dehydration, vomiting, diarrhea, interstitial fluid redistribution
    - cardiogenic: myopathic (myocardial ischemia ± infarction), mechanical, arrhythmic, pharmacologic
    - obstructive: massive PE (saddle embolus), pericardial tamponade, constrictive pericarditis, increased intrathoracic pressure (e.g. tension pneumothorax)
    - distributive: sepsis, anaphylactic reaction, neurogenic, endocrinologic, toxic

</tbody>
</table>

- treat underlying cause
- treatment goal is to return critical organ perfusion to normal (e.g. normalize BP)
- common treatment modalities include:
  - fluid resuscitation
  - inotropes (e.g. dobutamine), vasopressors (e.g. norepinephrine), vasopressin
  - revascularization or thrombolitics for ischemic events

Sepsis

- the leading cause of death in noncoronary ICU settings is multi-organ failure due to sepsis
- the predominant theory is that sepsis is attributable to uncontrollable immune system activation

Definitions
- sepsis: the presence of both infection and SIRS (see Table 35)
- severe sepsis: sepsis associated with organ dysfunction, hypoperfusion or hypotension
- septic shock: sepsis with arterial hypotension despite adequate fluid resuscitation
- multitorgan dysfunction syndrome: sepsis in the presence of altered organ function such that homeostasis cannot be maintained without intervention

Signs and Symptoms

</tbody>
</table>

Treatment
- identify the cause and source of infection: blood, sputum, urine Gram stain and C&S
- initiate empiric antibiotic therapy
- monitor, restore and maintain hemodynamic function

Early Goal Directed Therapy
- adjustments of cardiac preload, afterload and contractility to balance oxygen delivery with demand
- should be started immediately and completed within 6 h of recognition of severe sepsis or septic shock

Shock: Clinical Correlation
- Hypovolemic: patients have cool extremities due to peripheral vasoconstriction.
- Cardiogenic: patients usually have signs of left-sided heart failure.
- Obstructive: varied presentation.
- Distributive: patients have warm extremities due to peripheral vasodilation.

Causes of SHOCK
- Spinal (neurogenic), Septic
- Hemorrhagic
- Obstructive (e.g. tension pneumothorax, cardiac tamponade, PE)
- Cardiogenic (e.g. arrhythmia, MI)

Systemic Inflammatory Response Syndrome (SIRS): generalized inflammatory reaction caused by infectious and noninfectious entities, manifested by two or more of:
- Body temperature >38.5°C or <35°C
- Heart rate >90/min
- Respiratory rate >20/min or P<sub>CO2</sub> < 32 mmHg
- WBC >12000 cells/mL or <4000 cells/mL or >10% bands

Corticosteroids for Treating Severe Sepsis and Septic Shock
- Cochrane DB Syst Rev 2010;CD002243
- Study: Meta-analysis of 25 RCTs and quasi-RCTs examining the efficacy of corticosteroids on death at one month in patients with severe sepsis and septic shock.
- Results: Overall, there was no difference in 28-d all-cause mortality but there was significant heterogeneity in dosing strategy between the studies. Treatment with long course of low dose corticosteroids significantly reduced 28-d mortality, increased the proportion of shock reversal by day 7 and day 28, reduced the sepsis-related organ failure assessment score by day 7, and survivors’ length of stay in the ICU, without inducing gastroduodenal bleeding, superinfection, or neuromuscular weakness. Corticosteroids increased the risk of hyperglycemia and hypernatremia.
- Conclusion: Corticosteroids did not change mortality in severe sepsis and septic shock. A long course of low dose corticosteroids reduced 28-d mortality without major complications.
• patient should meet SIRS criteria and sBP <90 mmHg or lactate >4 mmol/L
  1. supplemental oxygen ± intubation and mechanical ventilation
  2. central venous and arterial catheterization
  3. maintain CVP 8-12 mmHg with IV crystalloids/colloids
  4. MAP maintained 65-90 mmHg with the use of vasoactive agents
  5. SaO2 <70% then
    • transfusion of red cells until Hct >30%
    • if SaO2 <70% after transfusion then use inotropes agents

• supportive oxygenation and ventilation using lung-protective regime
• early nutritional support: enteral route is used to preserve function of intestinal mucosal barrier
• control hyperglycemia with insulin to decrease infectious complications
• physiologic dose corticosteroid replacement therapy in patients with relative adrenal insufficiency (nonresponders to corticotropin stimulation test)
• consider in mechanically ventilated septic shock patients with organ dysfunction requiring vasopressors, despite early goal-directed therapy and appropriate antibiotic therapy
• recombinant activated protein C may be considered in patients with severe sepsis or septic shock with an APACHE II score >25 despite early goal-directed therapy and appropriate antibiotic therapy
• DVT/PE prophylaxis
• advanced care planning, including the communication of likely outcomes and realistic goals of treatment with patients and families

</tbody>
</table>

Immunogenetics and Disease

- cell surface molecules called human leukocyte antigen (HLA) play a role in mediating immune reactions
- major histocompatibility complex (MHC) are genes on the short arm of chromosome 6 that encode HLA molecules
- there are three classes of MHC (see Table 2)
- discrete domains of hypervariability within MHC molecules thought to represent "susceptibility determinants”
- certain HLA haplotypes are associated with increased susceptibility to autoimmune diseases (see Table 3)

Common Investigations in Rheumatology
- general: CBC, electrolytes, Cr
- acute phase reactants: ESR, CRP, ferritin, albumin, fibrinogen
- complement (C3, C4)
- urinalysis to detect disease complications (proteinuria, active sediment)
- serology: autoimmune Abs (ANA, anti-dsDNA, anti-Jo-1, anti-Sm, anti-La, anti-Ro, RhF, and anti-CCP, etc.)
- synovial fluid analysis
- radiology (plain film, CT, MRI, U/S, bone densitometry, angiography, bone scan)

**Synovial Fluid Analysis**
- synovial fluid is an ultrafiltrate of plasma plus hyaluronic acid; it lubricates joint surfaces and nourishes articular cartilage

**Indications**
- diagnostic: mandatory if septic arthritis suspected; advised if crystal arthritis or hemorrhatis suspected; advised if unexplained effusion in accessible joint
- therapeutic: drainage of blood, purulent or tense effusions; corticosteroid injection

**Contraindications**
- absolute: open lesion or suspected infection of overlying skin or soft tissue
- relative: bleeding diathesis, thrombocytopenia, prosthetic joint

**Most Important Tests of Synovial Fluid (3 Cs)**
- ensure synovial fluid is described in terms of colour, clarity, viscosity, and quantity
  1. Cell count and differential
  2. Culture and Gram stain (bacteria, mycobacteria, fungi)
  3. Crystal examination (microscopy with polarized light)
    - gout (monosodium urate) → needle-shaped, negatively birefringent (bright yellow)
    - pseudogout (calcium pyrophosphate dihydrate) → rhomboid-shaped, positively birefringent (pale blue)

Septic Arthritis

- for any acute monoarticular arthritis, one must rule out septic etiology; consider empiric antibiotic treatment until septic arthritis is excluded by history, physical exam and synovial fluid analysis
- poor prognostic factors: older age, immunocompromised, delay in treatment, previously damaged joint, joint prosthesis
- see Infectious Diseases for Gonococcal Arthritis, ID15/Orthopedics, OR10

Degenerative Arthritis: Osteoarthritis (OA)

Definition
- progressive deterioration of cartilage and bone due to failed repair of joint damage caused by stresses on the joint

Classification (based on etiology)
- primary (idiopathic)
  - most common, unknown etiology
- secondary
  - post-traumatic or mechanical
  - post-inflammatory (e.g. RA) or post-infectious
  - heritable skeletal disorders (e.g. scoliosis)
  - endocrine disorders (e.g. acromegaly, hyperparathyroidism, hypothyroidism)
  - metabolic disorders (e.g. gout, pseudogout, hemochromatosis, Wilson's disease, ochronosis)
  - neuropathic (e.g. Charcot joints)
    - atypical joint trauma due to peripheral neuropathy (e.g. diabetes, syphilis)
    - avascular necrosis
    - other (e.g. congenital malformation)

Pathophysiology
- deterioration of articular cartilage due to local biomechanical factors and release of proteolytic and collagenolytic enzymes
  - OA develops when cartilage catabolism > synthesis
  - loss of proteoglycans and water exposes underlying bone
- abnormal local bone metabolism further damages joint
- altered joint function and damage
- synovitis is secondary to cartilage damage; therefore, may see small effusions in OA

Epidemiology
- most common arthropathy
- increased prevalence with increasing age (35% of 30 yr olds, 85% of 80 yr olds)

Risk Factors
- genetic predisposition, advanced age, obesity (for knee OA), female, trauma

Signs and Symptoms
- localized to affected joints (not a systemic disease)
- pain is often insidious, gradually progressive, with intermittent flares and remissions

<table>
<thead>
<tr>
<th>Table 9. Signs and Symptoms of OA</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Signs</strong></td>
</tr>
<tr>
<td>Joint line tenderness; stress pain ≤ joint effusion</td>
</tr>
<tr>

<tr>
<td>Limited ROM</td>
</tr>
<tr>
<td>Crepitus on passive ROM</td>
</tr>
<tr>
<td>Inflammation (mild if present)</td>
</tr>
<tr>
<td>Periarticular muscle atrophy</td>
</tr>
</tbody>
</table>

Joint Involvement (see Figure 3)
- asymmetric
- hand (see Figure 4)
  - DIP (Heberden’s nodes = osteophytes → enlargement of joints)
  - PIP (Bouchard’s nodes)
  - CMC (usually thumb squaring)
  - 1st MCP (other MCPs are usually spared)
Seropositive Rheumatic Disease

- seropositive arthropathies are characterized by the presence of a serologic marker such as a positive rheumatoid factor or ANA
- the vasculitides are not seropositive diseases – some may be ANCA positive

Figure 5. Seropositive rheumatic diseases
Investigations

Bloodwork
- general: CBC, creatinine
- acute phase reactants: ESR, CRP, ferritin, albumin, complement (C3 and C4), fibrinogen,
- Note: C3, C4 often decrease in active SLE
- autoantibodies (see Table 10)

Urinalysis
- proteinuria, active sediment
- synovial fluid analysis (see Table 8)
- radiology (plain film, CT, MRI, ultrasound, bone densitometry, angiography, bone scan)

### Rheumatoid Arthritis (RA)

**Definition**
- chronic, symmetric, erosive synovitis of peripheral joints (i.e. wrists, MCPs, MTPs)
- characterized by a number of extra-articular features

#### Table 12. Classification Criteria for RA

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Score</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Joint involvement (swollen or tender)</td>
<td></td>
<td>Total score of ≥6: definite RA Must have at least ≥1 joint with definite clinical swelling, not better explained by other disease</td>
</tr>
<tr>
<td>1 large joint (shoulders, elbows, hips, knees, and ankles)</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>2-10 large joints</td>
<td>1</td>

<td>4. Duration of symptoms &lt;6 wk</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>≥6 wk</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

Pathophysiology
- autoimmune disorder, unknown etiology
- hallmark of RA is hypertrophy of the synovial membrane
- activated rheumatoid synovium (pannus) grows into and over the articular surface; inflammatory mediators lead to release of metalloproteinas and collagenases resulting in destruction of articular cartilage and subchondral bone
- two theories attempt to explain chronic remissions and exacerbations seen in RA
  - sequestered Ag
    - during inflammation, immune complexes (ICs) are deposited at avascular cartilage-bone junction
    - ICs are released as further cartilage breaks down
    - triggers inflammatory cascade
  - molecular mimicry
    - cartilage damage → altered cartilage resembles undefined offending agent → triggers inflammatory cascade

Epidemiology
- prevalence 1% of adult population
- F:M = 3:1
- age of onset 20-40 yr
- genetic predisposition: HLA-DR4/DR1 association (93% of patients have either HLA type)

Signs and Symptoms
- variable course of exacerbations and remissions
- morning stiffness >1 h, improves with use, increases with rest
- may have joint pain with activity
- symmetric joint involvement (see Figure 6)
- joint swelling, tender joints
- signs of mechanical joint damage: loss of motion, instability, deformity, crepitus
- constitutional symptoms: profound fatigue; rarely myalgia or weight loss
- extra-articular features (EAF) (see Table 13)
- limitation of function and decrease in global functional status
- complications of chronic synovitis
  - signs of mechanical joint damage: loss of motion, instability, deformity, crepitus
  - joint deformities (see Figure 7)
    - swan neck deformity, boutonnière deformity
    - ulnar deviation of MCP, radial deviation of wrist joint
    - hammer toe, mallet toe, claw toe
    - flexion contractures
  - atlanto-axial and subaxial subluxation
    - C-spine instability
    - neurological impingement (long tract signs)
    - difficult/dangerous intubation: risk of worsening subluxation and damage to spinal cord
- limited shoulder mobility, spontaneous tears of the rotator cuff leading to chronic spasm
- tenosynovitis → may cause rupture of tendons
- carpal tunnel syndrome
- ruptured Baker’s cyst (outpouching of synovium behind the knee); presentation similar to acute DVT

</tbody>
</table>

Classification of Global Functional Status in RA (American College of Rheumatology, 1991)
- Class I: able to perform usual ADLs (self-care, vocational, avocational)
- Class II: able to perform self-care and vocational activities, restriction of avocational activities
- Class III: able to perform self-care, restriction of vocational and avocational activities
- Class IV: limited ability to perform self-care, vocational, avocational activities

Table 13. Extra-Articular Features of RA Classified by Underlying Pathophysiology

Figure 7. Joint deformities

Syndromes in RA
- Sjögren’s syndrome (common): keratoconjunctivitis sicca and xerostomia (dry eyes and mouth)
- Caplan’s syndrome (rare): multiple pulmonary nodules and pneumoconiosis
- Felty’s syndrome (rare): arthritis, splenomegaly, neutropenia
1. Disease Modifying Anti-Rheumatic Drugs (DMARDs) and Biologics (see Table 32)
   - DMARDs: standard of care and should be started as soon as possible
   - treatments guided by disease severity and prognostic features
   - methotrexate is the gold standard and is first-line unless contraindicated
   - delayed onset of action (may take 8-12 wk)
   - potential toxicities: GI, hematologic, hepatic (liver enzymes), pulmonary, teratogenic
   - if inadequate response (3-6 mo) → combine or switch
   - add-ons include: hydroxychloroquine, sulfasalazine, leflunomide
   - biologics: indicated if inadequate response to DMARDs
     - can be combined with DMARD therapy
     - agents include abatacept, rituximab, tocilizumab
     - reassess every 3-6 mo and monitor disease severity

2. Reducing Inflammation and Pain
   - NSAIDs
     - individualize according to efficacy and tolerability
     - contraindicated or cautioned in some patients (e.g. PUD, ischemic cardiac disease, pregnancy, see Table 31), add acetaminophen ± opioid prn for synergistic pain control
   - corticosteroids
     - local
       - intra-articular injections to control symptoms in a specific joint
     - systemic (prednisone)
       - low dose (5-10 mg/d) useful for short term to improve symptoms if NSAIDs ineffective, to bridge gap until DMARD takes effect
       - do baseline DEXA bone density scan and consider bone supportive pharmacologic therapy if using corticosteroids >3 mo at >7.5 mg/d
       - cautions/contraindications: active infection, TB, osteoporosis, hypertension, gastric ulcer, diabetes

3. Surgical Therapy
   - indicated for structural joint damage
   - surgical options include: synovectomy, joint replacement, joint fusion, reconstruction/tendon repair

Investigations
- bloodwork
  - RF sensitivity ~80% but non-specific (see Table 10); may not be present at onset of symptoms
  - anti-CCP (cyclic citrullinated peptide): sensitivity ~80% but more specific; may precede onset of symptoms
  - increased disease activity is associated with decreased Hb (anemia of chronic disease), increased platelets, ESR, CRP, and RF
- imaging
  - x-rays may be entirely normal at onset
  - first change is periarticular osteopenia, followed by erosions
  - ultrasound, MRI may be used to image hands to detect early synovitis and erosions

Treatment
- goals of therapy: remission or lowest possible disease activity
  - control disease activity
  - relieve pain and stiffness
  - maintain function and lifestyle
  - prevent or control joint damage
  - key is early diagnosis and early intervention with disease-modifying anti-rheumatic drugs (DMARDs)
- “window of opportunity” = early treatment within first 3 mo of disease may allow better control/remission

Education
- The Arthritis Society (Canada) and Arthritis Foundation (U.S.) for educational resources

Behavioral
- exercise program (isometrics and active, gentle ROM exercise during flares, aquatic/aerobic/strengthening exercise between flares), assistive devices as needed
- job modification may be necessary

Pharmacologic
1. Disease Modifying Anti-Rheumatic Drugs (DMARDs) and Biologics (see Table 32)
   - DMARDs: standard of care and should be started as soon as possible
   - treatments guided by disease severity and prognostic features
   - methotrexate is the gold standard and is first-line unless contraindicated
   - delayed onset of action (may take 8-12 wk)
   - potential toxicities: GI, hematologic, hepatic (liver enzymes), pulmonary, teratogenic
   - if inadequate response (3-6 mo) → combine or switch
   - add-ons include: hydroxychloroquine, sulfasalazine, leflunomide
   - biologics: indicated if inadequate response to DMARDs
     - can be combined with DMARD therapy
     - agents include abatacept, rituximab, tocilizumab
     - reassess every 3-6 mo and monitor disease severity

2. Reducing Inflammation and Pain
   - NSAIDs
     - individualize according to efficacy and tolerability
     - contraindicated or cautioned in some patients (e.g. PUD, ischemic cardiac disease, pregnancy, see Table 31), add acetaminophen ± opioid prn for synergistic pain control
   - corticosteroids
     - local
       - intra-articular injections to control symptoms in a specific joint
     - systemic (prednisone)
       - low dose (5-10 mg/d) useful for short term to improve symptoms if NSAIDs ineffective, to bridge gap until DMARD takes effect
       - do baseline DEXA bone density scan and consider bone supportive pharmacologic therapy if using corticosteroids >3 mo at >7.5 mg/d
       - cautions/contraindications: active infection, TB, osteoporosis, hypertension, gastric ulcer, diabetes

Surgical Therapy
- indicated for structural joint damage
- surgical options include: synovectomy, joint replacement, joint fusion, reconstruction/tendon repair

Side Effects of Steroids
- Weight gain
- Osteoporosis
- Avascular necrosis (AVN)
- Cataracts, glaucoma
- Peptic ulcer disease (PUD)
- Susceptibility to infection
- Easy bruising
- Acne
- Hypertension
- Hyperlipidemia
- Hypokalemia, hyperglycemia
- Mood swings

Comparison of Treatment Strategies in Early Rheumatoid Arthritis
Study: RCT of 508 patients comparing 4 different treatment strategies for early rheumatoid arthritis (known as the BEST trial).

Intervention:
- Group 1: Sequential Monotherapy with traditional DMARDs
- Group 2: Step-Up Combination Therapy
- Group 3: Initial Combination Therapy with prednisone (high dose)
- Group 4: Initial Combination Therapy with infliximab

Results: Patients in groups 3 and 4 responded faster and had significantly greater overall change in physical function scores after the first year of treatment. By end of the second yr, groups 1 and 2 had achieved a similar response to groups 3 and 4. Groups 3 and 4 also showed significantly less radiologic progression of their disease over 2 yr than groups 1 and 2. There were no significant differences in toxicity levels between the 4 groups.

Conclusions: Initial combination therapy with prednisone or infliximab results in faster response rates. Whether faster initial response rates leads to better long-term disease outcomes has not yet been studied.
Systemic Lupus Erythematosus (SLE)

- please see Nephrology, NP24 and Dermatology, D39 for additional details

Definition
- chronic inflammatory multi-system disease of unknown etiology
- characterized by production of autoantibodies and diverse clinical manifestations

Table 14. Diagnostic Criteria of SLE: 4 or more of 11 must be present serially or simultaneously

<table>
<thead>

<td>Most sensitive test (98%), not specific</td>
</tr>
</tbody>
</table>

Note: “4, 7, 11” rule - 4 out of 11 criteria (4 lab, 7 clinical) for diagnosis
American College of Rheumatology, 1997 update

Etiology and Pathophysiology
- production of autoantibodies causing multi-organ inflammation
- multi-factorial etiology (see Figure 8)
- genetics
  - common association with HLA-B8/DR3; ~10% have positive family history
- estrogen
  - pre-pubertal and post-menopausal women have similar incidence to men
  - men with SLE have higher concentration of estrogenic metabolites
- infection
  - viral (non-specific stimulant of immune response)
- drug-induced
  - anti-hypertensives (hydralazine), anti-convulsants (phenytoin), anti-arrhythmics (procainamide), isoniazid, biologics, oral contraceptive pills
  - anti-histone antibodies are commonly seen in drug-induced lupus
  - symptoms resolve with discontinuation of offending drug

Epidemiology
- prevalence: 0.05% overall
- F:M = 10:1
- age of onset in reproductive yr (13-40)
- more common and severe in African-Americans and Asians
- bimodal mortality pattern
  - active SLE, active nephritis, infection secondary to steroid use
  - late (>10 yr)
  - inactive SLE, inactive nephritis, atherosclerosis likely due to chronic inflammation

Signs and Symptoms
- characterized by periods of exacerbation and remission

The Safety of Infliximab, Combined with Background Treatments, among Patients with Rheumatoid Arthritis and Various Comorbidities (START)
Arthritis Rheum 2006;54:1075-1086
Study: Multicenter RCT.
Patients: 1084 patients (mean age 52 yr, 80% female) with active moderate to severe rheumatoid arthritis despite treatment with methotrexate.
Intervention: Patients were randomized to receive infusions of placebo, infliximab dosed at 3 mg/kg, or infliximab dosed at 10 mg/kg at 0, 2, 6, and 14 wk, in addition to methotrexate.
Primary Outcome: Incidence of serious infection within 22 wk.
Results: Compared with the placebo group, the relative risk of developing serious infection at 3 mg/kg and 10 mg/kg of Infliximab was 1.0 (95% CI 0.3-3.1, p=0.995) and 3.1 (95% CI 1.2-7.9, p=0.013) respectively. In addition, 31% of patients receiving infliximab at 3 mg/kg and 32% of patients receiving infliximab at 10 mg/kg were able to achieve remission at 22 wk compared with only 14% of those receiving placebo (p=0.007, NNT=6).
Conclusions: Therapy with infliximab 3 mg/kg does not significantly increase the risk of serious infection in patients with active moderate to severe rheumatoid arthritis already receiving methotrexate. However, therapy with infliximab 10 mg/kg does significantly increase the risk of serious infection in this population.

</tbody>
</table>

Investigations

- blood work: ANA (sensitivity 98%, but poor specificity → used as a screening test, ANA titres are not useful to follow disease course)
- anti-dsDNA and anti-Sm are specific (95-99%)
- anti-dsDNA titer and serum complement (C3, C4) are useful to monitor treatment response in patients who are clinically and serologically concordant
  - anti-dsDNA increases and C3 and C4 decrease with disease activity
- anti-phospholipid antibodies (anti-cardiolipin Ab and lupus anticoagulant), may cause increased risk of clotting and increased aPTT

Treatment

- goals of therapy
  - treat early and avoid long term steroid use, if unavoidable see Endocrinology, E42 for osteoporosis management
  - if high doses of steroids necessary for long-term control, add steroid-sparing agents and taper when possible
  - treatment is tailored to organ system involved and severity of disease
  - all medications used to treat SLE require periodic monitoring for potential toxicity
- dermatologic
  - sunscreen, avoid UV light and estrogens
  - topical steroids, hydroxychloroquine
- musculoskeletal
  - NSAIDs ± gastroprotective agent for arthritis (also beneficial for pleuritis and pericarditis)
  - hydroxychloroquine improves long term control and prevents flares
  - bisphosphonates, calcium, vitamin D to combat osteoporosis
- organ-threatening disease
  - high-dose oral prednisone or IV methylprednisolone in severe disease
  - steroid-sparing agents: azathioprine, methotrexate, mycophenolate
  - IV cyclophosphamide for serious organ involvement (e.g. cerebritis or SLE nephritis)

Antiphospholipid Antibody Syndrome (APLA)

Definition

- multi-system vasculopathy manifested by recurrent thromboembolic events, spontaneous abortions and thrombocytopenia
- often presents with migraine-type headaches
- circulating anti-phospholipid autoantibodies interfere with coagulation cascade
- primary APLA: occurs in the absence of other disease
- secondary APLA: occurs in the setting of a connective tissue disease (including SLE), malignancy, drugs (hyalurazine, procainamide, phenytoin, interferon, quinidine), and infections (HIV, TB, hepatitis C, infectious mononucleosis)
- catastrophic APLA: development within 1 wk of small vessel thrombotic occlusion in ≥3 organ systems with positive anti-phospholipid antibodies (high mortality)
Table 16. Classification Criteria of APLA: 1 clinical and 1 laboratory criteria must be present

Signs and Symptoms
- see clinical criteria in Table 16
- hematologic
  - thrombocytopenia, hemolytic anemia, neutropenia
- dermatologic
  - livedo reticularis, Raynaud’s phenomenon, purpura, leg ulcers, and gangrene

Treatment
- thrombosis
  - lifelong anti-coagulation with warfarin
  - target INR 2.0-3.0 for first venous event, >3.0 for recurrent and/or arterial event
  - recurrent fetal loss
  - heparin/low molecular weight heparin ± Aspirin® during pregnancy
  - catastrophic APS
    - high-dose steroids, anti-coagulation, cyclophosphamide, plasmapheresis

Scleroderma

Definition
- a non-inflammatory autoimmune disorder characterized by widespread small vessel vasculopathy and fibrosis

| Scleroderma | Morphoea  
|-------------| Hard oval patches on the skin  
| Limited systemic sclerosis  
| Skin sclerosis restricted to hands, face, neck  
| 3rd to 4th decade  
| Pulmonary hypertension common  
| CREST (see sidebar) |
| Generalized (systemic sclerosis)  
| Diffuse systemic sclerosis  
| Widespread skin disease (proximal to wrist, can involve trunk), tendons  
| Early visceral involvement (renal, pulmonary fibrosis) |

| Localized (no involvement of internal organs)  
| Mostly children and young adults |
| Systemic sclerosis |

| Early viscerale involvement |
| Skin changes limited to digits |

Figure 9. Forms of scleroderma

Table 17. Classification Criteria of Systemic Sclerosis: 1 major or 2 minor criteria must be present

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
</table>
| Major | Scleroderma proximal to MCPs  
Skin tightness, thickening, non-pitting induration |
| Minor | Sclerodactyly  
Digital pitting scars or loss of substance from finger pad  
Ribosalar pulmonary fibrosis |

American Rheumatism Association, 1980

Etiology and Pathophysiology
- idiopathic vasculopathy (not vasculitis) leading to atrophy and fibrosis of tissues
  - intimal proliferation and media mucinous degeneration → progressive obliteration of vessel lumen → fibrotic tissue
  - resembles malignant hypertension

A Systematic Review of Secondary Thromboprophylaxis in Patients with Anti-phospholipid Antibodies

Arthritis Rheum 2007;57:1487-11495

Study: Review of RCTs, prospective and retrospective cohort studies, and subgroup analysis (n >15) that focused on the secondary thromboprophylaxis in patients with anti-phospholipid antibodies (aPL) were selected.

Results: Sixteen studies were selected. Patients with venous events and a single test for aPL showed a low recurrence rate while receiving oral anti-coagulation at a target INR of 2.0-3.0. Patients with stroke and a single positive aPL test had no increased risk compared with those without aPL. Recurrence rates in patients with definite anti-phospholipid syndrome (APLA) and previous venous thromboembolism were lower than in patients with arterial and/or recurrent events, both with and without therapy. Only 3.8% of recurrent events occurred at an actual INR >3.0. Mortality due to recurrent thrombosis was higher than mortality due to bleeding (18 patients versus 1 patient reported).

Conclusion: For patients with definite APLA, the authors recommend prolonged warfarin therapy at a target INR of 2.0-3.0. For patients with stroke and a single positive aPL test, the authors recommend further testing to determine if they have a persisting antibody. If they do not, the same therapy as for the general population should be used (warfarin at a target INR of 2.0-3.0 and low-dose Aspirin®, respectively).

CREST Syndrome
- Calcinoi: calcium deposits on skin  
- Raynaud’s phenomenon  
- Esophageal dysfunction: acid reflux  
- Sclerodactyly: tightening of skin on digits  
- Telangiectasia: superficial dilated blood vessels
Epidemiology
- F:M = 3-4:1, peaking in 5th and 6th decades
- associated with HLA-DR1
- associated with environmental exposure (silica, epoxy resins, toxic oil, aromatic hydrocarbons, polyvinyl chloride)
- limited systemic sclerosis has a higher survival prognosis (>70% at 10 yr) than diffuse systemic sclerosis (40-60% at 10 yr)

Signs and Symptoms

</tbody>
</table>

Investigations
- bloodwork
  - CBC, Cr, ANA
  - anti-topoisomerase 1/anti-Scl-70: specific but not sensitive for diffuse systemic sclerosis
  - anti-centromere: favours diagnosis of CREST (limited systemic sclerosis)
- PFT
  - assess for pulmonary hypertension or interstitial lung disease
- imaging
  - CXR for fibrosis, echo for pulmonary HTN

Treatment
- dermatologic
  - good skin hygiene
  - low-dose prednisone (>20 mg may provoke renal crisis if susceptible), methotrexate (limited evidence)
- vascular
  - patient education on cold avoidance
  - vasodilators (CCBs, local nitroglycerine cream, systemic PGE2 inhibitors, PDE5 inhibitors)
- gastrointestinal
  - GERD: PPIs are first line, then H2-receptor agonists
  - small bowel bacterial overgrowth: broad spectrum antibiotics (tetracycline, metronidazole)
- renal disease
  - ACE inhibitors for hypertensive crisis
- pulmonary
  - early interstitial disease: cyclophosphamide
  - pulmonary hypertension: vasodilators e.g. bosentan (Tracleer®), epoprostenol (Flolan®), PDE5 inhibitors
- cardiac
  - pericarditis: systemic steroids
- musculoskeletal
  - arthritis: NSAIDs
  - myositis: systemic steroids
Idiopathic Inflammatory Myopathy

Definition
- autoimmune diseases characterized by proximal muscle weakness ± pain
- muscle becomes damaged by a non-suppurative lymphocytic inflammatory process
- classification
  - polymyositis (PM)/dermatomyositis (DM) (see Table 19)
  - adult and juvenile form
  - associated with malignancy
    - increased risk of malignancy: age >50, DM>PM, normal CK, refractory disease
    - 2.4-6.5 fold increased risk of underlying malignancy usually in internal organs
    - associated with other connective tissue disease
    - inclusion body myositis (IBM)
      - age >50, M>F , slowly progressive, vacuoles in cells on biopsy
      - suspect when patient unresponsive to treatment
      - distal as well as proximal muscle weakness
      - muscle biopsy positive for inclusion bodies

POLYMYOSITIS (PM)/DERMATOMYOSITIS (DM)

Table 19. Classification Criteria for PM/DM. Definite if 4 present, probable if 3 present.

<table>
<thead>
<tr>
<th>Criteria</th>

</tr>
<tr>
<td>5. Typical rash of dermatomyositis</td>
<td>Required for diagnosis of DM (see below)</td>
</tr>
</tbody>
</table>

NEJM 1975;292:403-407

Etiology and Pathophysiology
- PM is CD8 cell-mediated muscle necrosis, found in adults
- DM is B-cell and CD4 immune complex-mediated peri-fascicular vascular abnormalities

Signs and Symptoms
- progressive symmetrical proximal muscle weakness (shoulder and hip) developing over weeks to months
- difficulty lifting head off pillow, arising from chair, climbing stairs
- dermatological
  - DM has characteristic dermatological features (F>M, children and adults)
    - Gottron’s papules
      - pink-violaceous, flat-topped papules overlying the dorsal surface of the interphalangeal joints
    - Gottron’s sign
      - erythematous, smooth or scaly patches over the dorsal IPs, MCPs, elbows, knees, or medial malleoli
    - heliotrope rash: violaceous rash over the eyelids; usually with edema
    -shawl sign: erythematous rash over neck, upper chest, and shoulders
    - mechanic’s hands: dark, dry, thick scale on palmar and lateral surface of digits
    - periungual erythema
- cardiac
  - dysrhythmias, CHF, conduction defect, ventricular hypertrophy, pericarditis
- gastrointestinal
  - oropharyngeal and lower esophageal dysphagia, reflux
- pulmonary
  - weakness of respiratory muscles, interstitial lung disease, aspiration pneumonia

Investigations
- bloodwork: CK, ANA, anti-Jo-1 (DM), anti-Mi-2, anti-SRP
- imaging: MRI may be used to localize biopsy site
- EMG, muscle biopsy

Treatment
- non-pharm: physical therapy and occupational therapy
- pharmacologic treatment:
  - high-dose corticosteroid (1-2 mg/kg/d) and slow taper
  - add immunosuppressive agents (azathioprine, methotrexate, cyclosporine)
  - intravenous immunoglobulin if severe or refractory
  - hydroxychloroquine for DM rash
Sjögren’s Syndrome (SS)

Definition
- autoimmune condition characterized by dry eyes (keratoconjunctivitis sicca/xerophthalmia) and dry mouth (xerostomia), caused by lymphocytic infiltration of salivary and lacrimal glands
- may evolve into systemic disorder with diminished exocrine gland activity in respiratory tract and skin
- primary and secondary form (associated with RA, SLE, DM and HIV)
- incidence estimated at 4/100,000 people
- 90% of cases are among females
- mean age of diagnosis is 40-60 yr

Table 20. Classification Criteria for SS. Need 4 present, one of which includes salivary gland biopsy or autoantibodies

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Dry eye symptoms</td>
<td>Dry &gt;3 mo, foreign body sensation, or requiring tear substitutes</td>
</tr>
<tr>
<td>2. Dry mouth symptoms</td>

<td>Focal lymphocytic sialoadenitis</td>
</tr>
<tr>
<td>6. Autoantibodies</td>
<td>anti-Ro and/or anti-La, ANA, RF</td>
</tr>
</tbody>
</table>

Signs and Symptoms
- "sicca complex": dry eyes (keratoconjunctivitis sicca/xerophthalmia), dry mouth (xerostomia)
- staphylococcus blepharitis
- dental caries, oral candidiasis, angular chelitis (inflammation and fissuring at the labial commissures of the mouth)
- systemic complications
  - sinusitis, autoimmune thyroid dysfunction
  - arthralgias, arthritis
  - subclinical diffuse interstitial lung disease, xerotrachea leading to chronic dry cough
  - renal disease, glomerulonephritis
  - palpable purpura, vasculitis
  - peripheral neuropathy
  - lymphoma risk greatly increased

Treatment
- ocular
  - artificial tears or surgical punctal occlusion for dry eyes
- oral
  - good dental hygiene, hydration
  - agents that stimulate salivary flow (e.g. pilocarpine)
  - topical nystatin or clotrimazole x 4-6 wk for oral candidiasis
- systemic
  - e.g. hydroxychloroquine, corticosteroids

Mixed Connective Tissue Disease (MCTD)/Overlap Syndrome
- syndrome with features of 3 different CTD (e.g. SLE, scleroderma, PM)
- common symptoms: Raynaud’s phenomenon, swollen fingers
- bloodwork: anti-RNP (see Table 10)
- treatment is generally guided by the severity of symptoms and organ system involvement
- prognosis
  - 50-60% will evolve into SLE
  - 40% will evolve into scleroderma
  - only 10% will remain as MCTD for the rest of their lives
  - cardiac involvement (dysrhythmia) common, renal or lung involvement rare
## Vasculitides

- inflammation and subsequent necrosis of blood vessels leading to tissue ischemia or infarction
- any organ system can be involved
- keys to diagnosis
  - clinical suspicion: suspect in cases of unexplained multiple organ ischemia or systemic illness with no evidence of malignancy or infection
  - labs non-specific: anemia, increased WBC and ESR, abnormal urinalysis
  - biopsy if tissue accessible
  - angiography if tissue inaccessible
- treatment generally involves corticosteroids and/or immunosuppressive agents

### c-ANCA:
- circulating anti-neutrophil cytoplasmic antibody associated with anti PR3.

### p-ANCA:
- perinuclear anti-neutrophil cytoplasmic antibody associated with multiple antigens, e.g. lactoferrin (IBD), myeloperoxidase (microscopic polyangiitis).

### Features of Small Vessel Vasculitis
- Palpable purpura
- Vesicles
- Chronic urticaria
- Superficial ulcers

### Churg-Strauss Triad
- Allergic rhinitis and asthma (often quiescent at time of vasculitis)
- Eosinophilic infiltrative disease resembling pneumonia
- Systemic vasculitis often mononeuritis multiplex/peripheral neuropathy and peripheral eosinophilia

### Features of Medium Vessel Vasculitis
- Livedo reticularis
- Erythema nodosum
- Raynaud’s phenomenon
- Nodules
- Digital infarcts
- Ulcers
Small Vessel Non-ANCA Associated Vasculitis

PREDOMINANTLY CUTANEOUS VASCULITIS
- subdivided into
  - drug-induced vasculitis
  - serum sickness reaction
  - vasculitis associated with other underlying primary diseases

Etiology and Pathophysiology
- cutaneous vasculitis following
  - drug exposure (allopurinol, gold, sulfonamides, penicillin, phenytoin)
  - viral or bacterial infection
  - idiopathic causes
- small vessels involved (post-capillary vessels most frequently)
- usually causes a leukocytoclastic vasculitis: debris from neutrophils around vessels
- sometimes due to cryoglobulins which precipitate in cold temperatures

Signs and Symptoms
- palpable purpura ± vesicles and ulceration, urticaria, macules, papules, bullae, subcutaneous nodules

Investigations
- vascular involvement (both arteriole and venule) established by skin biopsy

Treatment
- stop possible offending drug
- corticosteroids ± immunosuppressive agents
- usually self-limiting

Small Vessel ANCA-Associated Vasculitis

GRANULOMATOSIS WITH POLYANGIITIS (formerly known as Wegener’s Granulomatosis)

Definition
- granulomatous inflammation of vessels that may affect the upper airways (rhinitis, sinusitis), lungs (pulmonary nodules, infiltrates), and kidneys (glomerulonephritis, renal failure)
- highly associated with c-ANCA
- incidence 5 per 100,000; more common in Northern latitudes

Table 22. Classification Criteria for GPA. Diagnosed if 2 or more of the following 4 criteria present.

</tr>
</tbody>
</table>

American College of Rheumatology, 1990
Etiology
- pathology is complex, possibly involving transformation from inflammatory prodrome (serous otitis media and sinusitis) to full-blown vasculitic syndrome

Signs and Symptoms
- systemic
  - malaise, fever, weakness, weight loss
- HEENT
  - sinusitis or rhinitis, nasal crusting and bloody nasal discharge, nasoseptal perforation, saddle nose deformity
  - proptosis due to: inflammation/vasculitis involving extra-ocular muscles, retrobulbar space occupying lesions or direct extension of masses from the upper respiratory tract
  - hearing loss due to involvement of CN VIII
- pulmonary
  - cough, hemoptysis
- renal
  - hematuria
- other
  - joint, skin, eye complaints, vasculitic neuropathy

Investigations
- bloodwork: anemia (normal MCV), increased WBC, increased Cr, increased ESR, ANCA pR3 > MPO
- urinalysis: proteinuria, hematuria, RBC casts
- CXR: pneumonitis, lung nodules, infiltrations, cavitary lesions
- biopsy: renal (segmental necrotizing glomerulonephritis), lung (granulomas, tracheobronchial erosion)
- possible decline in c-ANCA and ESR used to monitor response to treatment in some patients

Treatment
- prednisone 1 mg/kg/d PO for 3-6 mo ± cyclophosphamide 2 mg/kg/d PO for 3-6 mo followed by high dose methotrexate (20-25 mg PO/SC weekly) or azathioprine (2 mg/kg/d PO once daily)
- consider biologic agents (rituximab, IVIG) and plasmapheresis (PEXIVAS trial)
- RAVE trial (NEJM 2010; 363:221-232): rituximab equivalent or superior to cyclophosphamide with less toxicity

Medium Vessel Vasculitis

POLYARTERITIS NODOSA (PAN)

Definition
- systemic, necrotizing vasculitis of medium sized vessels
- ANCA negative
- often associated with hepatitis B positivity
- incidence 0.7 per 100,000; affects individuals between 40-60 yr; M:F = 2:1

</tbody>
</table>

American College of Rheumatology, 1990

Etiology and Pathophysiology
- focal panmural necrotizing inflammatory lesions in small and medium-sized arteries
- thrombosis, aneurysm, or dilatation at lesion site may occur
- healed lesions show proliferation of fibrous tissue and endothelial cells that may lead to luminal occlusion
Investigations
• bloodwork: CBC, ESR, Cr, BUN, p-ANCA, hepatitis B serology
• imaging: angiography
• arterial biopsy

Treatment
• prednisone 1 mg/kg/d PO and cyclophosphamide 2 mg/kg/d PO
• ± anti-viral therapy to enhance clearance of HBV

Large Vessel Vasculitis
• please see Neurology, N39 and Ophthalmology, OP38 for more details

</table>

American College of Rheumatology, 1990

Epidemiology
• most frequent vasculitis in North America
• patients >50 yr
• F:M = 2:1
• North-South gradient (predominance in Northern Europe/US)
• affects extracranial arteries

Signs and Symptoms
• new onset temporal headache ± scalp tenderness due to inflammation of involved portion of the temporal or occipital arteries
• sudden, painless loss of vision and/or diplopia due to narrowing of the ophthalmic or posterior ciliary arteries (PCA more common); can affect both eyes
• tongue and jaw claudication (pain in muscles of mastication on prolonged chewing)
• polymyalgia rheumatica (proximal myalgia, constitutional symptoms, elevated ESR) occurs in 30% of patients
• aortic arch syndrome (involvement of subclavian and brachial branches of aorta result in pulseless disease), aortic aneurysm ± rupture are late complications

Investigations
• diagnosis made by clinical suspicion, increased ESR, increased CRP, temporal artery biopsy within 14 d of starting steroids, possible ultrasound

Treatment
• if suspect GCA, immediately start high dose prednisone 1 mg/kg in divided doses for approximately 4 wk, and then tapering prednisone as symptoms resolve; highly effective in treatment and in prevention of blindness and other vascular complications
• consider low dose ASA

Prognosis
• increased risk of thoracic aortic aneurysm and aortic dissection
• yearly CXR ± abdominal ultrasound as screening

Ankylosing Spondylitis (AS)

Definition
- chronic inflammatory arthritis involving the sacroiliac joints and vertebrae (see Figure 12)
- AS in women: more peripheral arthritis and upper spine spondylitis
- prototype of the spondyloarthropathies

Table 26. ASAS Classification Criteria for Axial Spondyloarthritis (for patients with ≥3 months back pain and age at onset <45 years)

| Sacroiliitis on imaging plus ≥1 SpA feature or HLA B-27 positive plus ≥2 SpA features |
|---------------------------------|---------------------------------|---------------------------------|---------------------------------|
| SpA features:                   | Sacroiliitis on imaging:        |                                 |                                 |
| • Inflammatory back pain        | • Active (acute) inflammation on MRI highly suggestive of sacroiliitis associated with SpA |
| • Arthritis                     | • Definite radiographic sacroiliitis according to modified NY criteria |
| • Enthesitis (heel)             |                                 |                                 |                                 |
| • Uveitis                       |                                 |                                 |                                 |
| • Dactylitis                    |                                 |                                 |                                 |
| • Psoriasis                     |                                 |                                 |                                 |
| • Crohn’s disease/colitis       |                                 |                                 |                                 |
| • Good response to NSAIDs       |                                 |                                 |                                 |
| • Family history of SpA         |                                 |                                 |                                 |
| • HLA-B27 positive              |                                 |                                 |                                 |
| • Elevated CRP                  |                                 |                                 |                                 |

Etiology and Pathophysiology
- enthesitis (inflammation of tendon or ligament at site of attachment to bone)
- inflammation → osteopenia → erosion → ossification → osteoproliferation (syndesmophytes)

Epidemiology
- M:F = 5:1; females have milder disease which may be under-recognized
- 95% of patients have HLA-B27 (9% HLA-B27 positive in general population)

</table>

### Signs and Symptoms

- **axial**
  - mid and lower back stiffness, prolonged morning stiffness, night pain, persistent buttock pain, painful sacroiliac joint (+ Faber test) (see Table 27)
  - spinal restriction (decreased ROM): lumbar (decreased Schöber), thoracic (decreased chest wall expansion, normal >5 cm at T4), cervical (global decrease, often extension first)
  - postural changes: decreased lumbar lordosis + increased thoracic kyphosis + increased cervical flexion = increased occiput to wall distance (>5 cm)
- **peripheral**
  - asymmetrical large joint arthritis, most often involving lower limb
  - enthesitis: tenderness over tibial tuberosity, or Achilles tendon and plantar fascia insertions into the calcaneus
- **extra-articular manifestations**
  - ophthalmic: acute anterior uveitis is common (25-30% patients)
  - renal: amyloidosis (late and rare) and IgA nephropathy
  - gastrointestinal: inflammatory bowel disease
  - cardiac: aortitis, aortic regurgitation, pericarditis, conduction disturbances, heart failure (rare)
  - respiratory: apical fibrosis (rare)
  - neurologic: cauda equina syndrome (rare)
  - skin: psoriasis

### Investigations

- x-ray of SI joint: “pseudowidening” of joint due to erosion with joint sclerosis → bony fusion (late), symmetric sacroiliitis
- x-ray of spine: “squaring of edges” from erosion and sclerosis on corners of vertebral bodies (shiny corner sign) leading to ossification of outer fibres of annulus fibrosis (bridging syndesmophytes) → “bamboo spine” radiographically
- MRI of spine: assess activity in early disease; detection of cartilage changes, bone marrow edema, bone erosions, and subchondral bone changes. Best seen on T2 STIR images (suppress fat and see bone edema)

### Treatment

- **conservative/non-pharmacologic**
  - prevent fusion from poor posture and disability through: exercise (e.g. swimming), postural and deep breathing exercises, outpatient PT, smoking cessation
- **medical**
  - NSAIDs (first line of treatment)
  - glucocorticoids (topical eye drops, local injections)
  - DMARDs for peripheral arthritis (sulfasalazine, methotrexate)
  - biologics for axial and peripheral involvement
  - manage extra-articular manifestations
- **surgical**
  - hip replacement, vertebral osteotomy for marked deformity

### Prognosis

- spontaneous remissions and relapses are common and can occur at any age
- function may be excellent despite spinal deformity
- favourable prognosis if female and age of onset >40 yr
- early onset with hip disease may lead to severe disability; may require arthroplasty
Enteropathic Arthritis (EA)

- see Gastroenterology, Inflammatory Bowel Disease, G19
- MSK manifestations in the setting of either ulcerative colitis (UC) or Crohn’s disease (CD) include peripheral arthritis (large joint, asymmetrical), spondylitis, and hypertrophic osteoarthritis
- arthralgia, myalgia, osteoporosis and aseptic necrosis of bone 2° to steroid treatment of bowel inflammation
- NSAIDs should be used cautiously as they may exacerbate bowel disease

Psoriatic Arthritis (PsA)

Etiology and Pathophysiology
- unclear but many genetic, immunologic and some environmental factors involved (e.g. psoriatic plaque flora, particularly Group A Streptococcus, and trauma)

Epidemiology
- psoriasis affects 1% of population
- arthropathy in 10% of patients with psoriasis
- 15-20% of patients will develop joint disease before skin lesions appear

Signs and Symptoms
- dermatologic
  - well-demarcated erythematous plaques with silvery scale
  - nail involvement: pitting, transverse or longitudinal ridging, discoulouration, subungual hyperkeratosis, onycholysis, and oil drops
- musculoskeletal
  - 5 general patterns
    - asymmetric oligoarthritis (most common – 70%)
    - arthritis of DIP joints with nail changes
    - destructive (mutans) arthritis (5%)
    - symmetric polyarthritis (similar to RA)
    - sacroiliitis and spondylitis (usually older, male patients)
  - other findings: dactylitis, enthesopathy
- ophthalmic
  - conjunctivitis, iritis (anterior uveitis)
- cardiac and respiratory (late findings)
  - aortic insufficiency
  - apical lung fibrosis
- neurologic
  - cauda equina syndrome
- radiologic
  - floating syndesmophytes
  - pencil-in-cup appearance at IP joints
  - osteolysis, periostitis

Treatment
- treat skin lesions (e.g. steroid cream, salicylic and/or retinoic acid, tar, UV light)
- NSAIDs or intra-articular steroids
- DMARDs, biologic therapies to minimize erosive disease (use early if peripheral joint involvement)

Reactive Arthritis (ReA)

Definition
- two meanings
  1. Reactive arthritis: a sterile arthritis following an infection (e.g. rheumatic fever, post-viral arthritis, etc.), not used frequently by rheumatologists
  2. Reactive Arthritis (ReA): one of the seronegative spondyloarthropathies in which patients have a peripheral arthritis (≥1 mo duration) accompanied by one or more extra-articular manifestations that appears shortly after certain infections of the GI or GU tracts
Etiology
• onset following an infectious episode either involving the GI or GU tract
  - GI: *Shigella*, *Salmonella*, *Campylobacter*, *Yersinia* species
  - GU: *Chlamydia* (isolated in 16–44% of ReA cases), *Mycoplasma* species
• acute clinical course
  - 1-4 wk post-infection
  - lasts weeks to years
  - often recurring
  - spinal involvement persists

Epidemiology
• in HLA-B27 patients, axial > peripheral involvement
• M>F

Signs and Symptoms
• musculoskeletal
  - peripheral arthritis, asymmetric pattern, spondylitis, Achilles tendinitis, plantar fasciitis, dactylitis
• ophthalmic
  - iritis (anterior uveitis), conjunctivitis
• dermatomic
  - keratoderma blenorrhagicum (hyperkeratotic skin lesions on palms and soles) and balanitis cirinata (small, shallow, painless ulcers of glans penis and urethral meatus) are diagnostic
• gastrointestinal
  - oral ulcers, diarrhea
• urethritis and cervicitis
  - sterile cultures; presence not related to site of initiating infection

Investigations
• diagnosis is clinical plus laboratory
• bloodwork: normocytic, normochromic anemia and leukocytosis
• sterile cultures
• serology: HLA-B27 positive

Treatment
• antibiotics for non-articular infections
• NSAIDs, physical therapy, exercise
• local therapy
  - joint protection
  - intra-articular steroid injection
  - topical steroid for ocular involvement
• systemic therapy
  - corticosteroids, sulfasalazine, methotrexate (for peripheral joint involvement only)
  - TNF-α inhibitors for spinal inflammation

Prognosis
• self-limited, typically 3-5 mo, varies based on pathogen and patient’s genetic background
• chronic in 15-20% of cases

*Clinical triad of reactive arthritis:*
- Arthritis
- Conjunctivitis
- Urethritis/cervicitis

*“Can’t see, can’t pee, can’t climb a tree”:* Triad of conjunctivitis, urethritis, and arthritis is 99% specific (but 51% sensitive) for ReA.
Gout

Definition
- derangement in purine metabolism resulting in hyperuricemia; monosodium urate crystal deposits in tissues (tophi) and synovium (microtophi)

Etiology and Pathogenesis
- sources of uric acid: diet and endogenous
  - synthesis
    - hypoxanthine $\rightarrow$ xanthine $\rightarrow$ uric acid
    - both steps catalyzed by xanthine oxidase
- hyperuricemia
  - primary or genetic
    - mostly due to idiopathic renal underexcretion (90%)
    - also idiopathic overproduction or abnormal enzyme production/function
  - secondary
    - dietary excess (particularly high consumption of beer, seafood, and meat)
    - underexcretion (>90%): renal failure, drugs, systemic conditions
    - overproduction (<10%): increased nucleic acid turnover states (e.g. malignancy, post-chemotherapy)
- sudden changes (increasing or decreasing) in uric acid concentration are more important than absolute values
- acute gout can occur with normal serum uric acid
- changes in pH, temperature or initiation of antihyperuricemics may precipitate an acute gouty attack
- common precipitants: alcohol, dietary excess, dehydration, drugs (e.g. thiazide and loop diuretics), trauma, illness, surgery, starting xanthine oxidase inhibitor therapy
- other associated conditions: hypertension, obesity, diabetes, starvation

Epidemiology
- most common in males >45 yr old
- extremely rare in premenopausal female

Signs and Symptoms
- single episode progressing to recurrent episodes of acute inflammatory arthritis
- acute gouty arthritis
  - severe pain, redness, joint swelling, usually involving lower extremities (see Figure 13)
  - joint mobility may be limited
  - attack will subside spontaneously within several days to weeks; may recur
- tophi
  - urate deposits on cartilage, tendons, bursae, soft tissues, and synovial membranes
  - common sites: first MTP, ear helix, olecranon bursae, tendon insertions (common in Achilles tendon)
- kidney
  - gouty nephropathy
  - uric acid calculi

Investigations
- joint aspirate: >90% of joint aspirates show crystals of monosodium urate (see Table 29) (negatively birefringent, needle-shaped)
- x-rays may show tophi as soft tissue swelling, punched-out lesions – erosion with "overhanging" edge

Treatment
- acute gout
  - NSAIDs: high dose, then taper as symptoms improve
  - corticosteroids: intra-articular, oral or intra-muscular (if renal, cardiovascular, or GI disease and/or if NSAIDs contraindicated or failed)
  - colchicine within first 12 h but effectiveness limited by narrow therapeutic range
  - allopurinol can worsen an acute attack (do not start during acute flare)
- chronic gout
  - conservative
    - avoid foods with high purine content (e.g. visceral meats, sardines, shellfish, beans, peas)
    - avoid drugs with hyperuricemic effects (e.g. pyrazinamide, ethambutol, thiazide, alcohol)
  - medical
    - antihyperuricemic drugs (allopurinol and febuxostat): decrease uric acid production by inhibiting xanthine oxidase
    - uricosuric drugs (probenecid, sulfinpyrazone): use if failure on or intolerant to allopurinol; do not use in renal failure
    - prophylaxis prior to starting antihyperuricemics drugs (colchicine/low-dose NSAID)
    - in renal disease secondary to hyperuricemia, use low-dose allopurinol and monitor creatinine
- indications for treatment with antihyperuricemic medications include:
  - recurrent attacks, tophi, bone erosions, urate kidney stones. Perhaps in renal dysfunction with very high urate load (controversial)

Precipitants of Gout
- Drugs are FACT
  - Furosemide
  - Aspirin®/Alcohol
  - Cytotoxic drugs
  - Thiazide diuretics
- Foods are SALT
  - Seafood
  - Alcohol (beer and spirits)
  - Liver and kidney
  - Turkey (meat)

Figure 13. Common sites of involvement in gout (asymmetric joint involvement)

An acute gout attack may mimic cellulitis. However, joint mobility is preserved in cellulitis. Gout often affects more than one joint (i.e. ankle, midfoot and MTPs).
Pseudogout (Calcium Pyrophosphate Dihydrate Disease)

Etiology and Pathophysiology
- acute inflammatory arthritis due to phagocytosis of IgG-coated calcium pyrophosphate dihydrate (CPPD) crystals by neutrophils and subsequent release of inflammatory mediators within joint space

Epidemiology
- more frequently polyarticular
- slower in onset in comparison to gout, lasts up to 3 wk but is self-limited

Risk Factors
- old age, advanced OA, neuropathic joints
- other associated conditions: hyperparathyroidism, hypothyroidism, hypomagnesemia, hypophosphatasia (low ALP), diabetes, hemochromatosis

Signs and Symptoms
- affects knees, wrists, MCPs, hips, shoulders, elbows, ankles, big toe (see Figure 14)
- multiple manifestations:
  - asymptomatic crystal deposition (seen on radiograph only)
  - acute crystal arthritis (self-limited flares of acute inflammatory arthritis resembling gout)
  - pseudo-osteoarthritis (progressive joint degeneration, sometimes with episodes of acute inflammatory arthritis)
  - pseudo-rheumatoid arthritis (symmetrical polyarticular pattern with morning stiffness and constitutional symptoms)
- acute may be triggered by dehydration, acute illness, surgery, trauma

Investigations
- must aspirate joint to rule out septic arthritis, gout
- CPPD crystals: present in 60% of patients, often only a few crystals
- x-rays show chondrocalcinosis in 75%: radiodensities in fibrocartilaginous structures (e.g. knee menisci) or linear radiodensities in hyaline articular cartilage

Treatment
- joint aspiration, rest, and protection
- NSAIDs: also used for maintenance therapy
- prophylactic colchicine PO (controversial)
- intra-articular or oral steroids to relieve inflammation

Pediatric Rheumatology
- see Pediatrics, P96

Non-Articular Rheumatism

Definition
- disorders that primarily affect soft tissues or periarticular structures
- includes bursitis, tendinitis, tenosynovitis, fibromyalgia, and polymyalgia rheumatica

Polymyalgia Rheumatica (PMR)

Definition
- characterized by pain and stiffness of the proximal extremities (girdle area)
- closely related to giant cell arteritis (15% of patients with PMR develop GCA)
- no muscle weakness
Table 30. PMR Classification Criteria Scoring Algorithm

| Required criteria: age ≥50, bilateral shoulder aching, and abnormal ESR/CRP |
|-----------------------------|-----------------------------|-----------------------------|
| Morning stiffness duration >45 min | 2 | 2 |
| Hip pain or limited ROM | 1 | 1 |
| Absence of RF or ACPA | 2 | 2 |
| Absence of other joint involvement | 1 | 1 |
| At least one shoulder with subdeltoid and/or biceps tenosynovitis and/or glenohumeral synovitis (either posterior or axillary) and at least one hip with synovitis and/or trochanteric bursitis on U/S | N/A | 1 |
| Both shoulders with subdeltoid bursitis, biceps tenosynovitis or gleno-humeral synovitis on U/S | N/A | 1 |

**A score of 4 or more is categorized as PMR in the algorithm without U/S and a score of 5 or more is categorized as PMR in the algorithm with U/S**

**Optional U/S criteria**

Epidemiology
- incidence 50 per 100,000 per year in those over age 50
- age of onset typically >50, F:M = 2:1

Signs and Symptoms
- constitutional symptoms prominent (fever, weight loss, malaise)
- pain and stiffness of symmetrical proximal muscles (neck, shoulder and hip girdles, thighs)
- gel phenomenon (stiffness after prolonged inactivity)
- physical examination reveals tender muscles, but no weakness or atrophy

Investigations
- bloodwork: often shows anemia, elevated platelets, elevated ESR and CRP; normal CK up to 5% of PMR reported with normal inflammatory markers

Treatment
- goal of therapy: symptom relief
- start with prednisone dose of 15-20 mg PO once daily
- taper slowly over 2-yr period monitoring ESR and symptoms closely
- treat relapses aggressively (50% relapse rate)
- monitor for steroid side effects, glucocorticoid-induced osteoporosis prevention, follow for symptoms of giant cell arteritis

Fibromyalgia

Definition
- chronic (>3 mo), widespread (axial, left- and right-sided, upper and lower segment), non-articular pain with characteristic tender points

Diagnosis

2010 Diagnostic Criteria for Fibromyalgia
1. Widespread pain index (WPI) ≥7 and symptom severity score (SS) ≥5 or WPI 3-6 and SS ≥9
2. Symptoms have been present at a similar level for ≥3 mo
3. The patient does not have a disorder that would otherwise explain the pain
   - WPI = number of areas in which the patient had pain over the last week (L and R: shoulder girdle, upper arm, lower arm, hip, upper leg, lower leg, jaw, chest, abdomen, upper and lower back, neck = max score 19)
   - SS = sum of a) severity of fatigue, b) waking unrefreshed, and c) cognitive symptoms over the past week, plus d) extent of somatic symptoms (IBS, headache, abdominal pain/cramps, dry mouth, fever, hives, ringing in ears, vomiting, heartburn, dry eyes, SOB, loss of appetite, rash, hair loss, easy bruising, etc.); all (a-d) rated on 0-3 scale: 0=no problem, 1 = mild, 2 = moderate, 3 = severe
- this clinical definition identified 88.1% of ACR classified fibromyalgia and can allow longitudinal assessment of symptom severity

Epidemiology
- F:M = 3:1
- primarily ages 25-45, some adolescents
- prevalence of 2-5% in general population
- overlaps with chronic fatigue syndrome and myofascial pain syndrome
- strong association with psychiatric illness
Signs and Symptoms
- widespread aching, stiffness
- easy fatigability
- sleep disturbance: non-restorative sleep, difficulty falling asleep, and frequent wakening
- symptoms aggravated by physical activity, poor sleep, emotional stress
- patient feels that joints are diffusely swollen although joint examination is normal
- neurologic symptoms of hyperalgesia, paresthesias
- associated with irritable bowel or bladder syndrome, migraines, tension headaches, restless legs syndrome, obesity, depression, and anxiety

Investigations
- bloodwork: includes TSH and ESR; all typically normal unless unrelated, underlying illness present
- serology: do not order ANA or RF unless there is clinical suspicion for a connective tissue disease
- laboratory sleep assessment

Differential Diagnosis
- diagnosis of exclusion
- rule out other disorders by history and physical exam

Treatment
- conservative
  - education
  - exercise program (walking, aquatic exercises), physical therapy (good posture, stretching, muscle strengthening, massage)
  - stress reduction, CBT
  - biofeedback, meditation, acupuncture may be helpful
- medical
  - low dose tricyclic antidepressant (e.g. amitriptyline)
  - for sleep restoration
  - select those with lower anticholinergic side effects
  - SNRI: duloxetine, milnacipran
  - anticonvulsant: pregabalin, gabapentin
  - analgesics may be beneficial for pain that interferes with sleep (NSAIDs, not narcotics)

Prognosis
- variable; usually chronic, unless diagnosed and treated early

Adult Onset Still’s Disease

Definition
- systemic inflammatory condition (ANA and RF negative) with fevers and characteristic rash, numerous systemic symptoms, may have severe arthritis

Etiology and Pathophysiology
- idiopathic; infectious triggers likely – various viruses and bacteria have been implicated
- stress increases risk

Epidemiology
- F>M; age of onset typically 16-40, approximately 1 per 100,000

Signs and Symptoms
- classic triad of symptoms:
  - high-spiking fevers (95.7% of patients, typically T 39°C, <4 h duration, quotidian pattern)
  - characteristic “salmon rash” (~72% of patients, on proximal limbs + trunk)
  - arthralgia/arthritis (64-100%)
- sore throat, myalgias and serositis may also occur
- arthritis is symmetric, typically affects large joints, i.e. wrists, knees and ankles, may involve PIP and DIPs, elbow, MTPs
- liver abnormalities ± hepatomegaly (50-75% patients)
- splenomegaly (44%)

Exercises for Treating Fibromyalgia Syndrome
- Cochrane DB Syst Rev 2008;CD003786
- Study: Systemic review of exercise training including cardiorespiratory endurance, muscle strengthening, and flexibility for global well-being and physical function in patients with fibromyalgia.
- Result: 24 studies were included (n = 2276).
- Aerobic-only exercises improve global well-being, physical function, and possibly pain and tender points. There was insufficient data to evaluate the effect of strength and flexibility on the primary outcomes.
- Conclusions: Moderate aerobic cardiorespiratory exercise improves function and well-being in patients with FM. Benefits from strength and flexibility require additional research to delineate benefits.

Fibromyalgia
- Study: Multicenter RCT. 750 patients with fibromyalgia with pain score of <40 mm on the visual analog scale (VAS) were assigned to placebo or pregabalin (300 mg, 450 mg, or 600 mg) daily for 12 wk.
- Primary Outcome: Change in the mean pain score derived from the subject’s daily pain diary as measured at the patient’s baseline to the end point of the study.
- Results: Patients treated with 450 and 600 mg/d pregabalin showed a statistically significant improvement in the end point mean pain score compared with placebo-treated subjects by -0.45 and -0.65 respectively.
- The 30% responder rate was 30%, 43%, 50%, and 48% in the placebo, 300 mg/d, 450 mg/d, an 600 mg/d respectively. The 50% responder rate was 15%, 24%, 27%, and 30% for placebo, 300 mg/d, 450 mg/d, and 600 mg/d respectively.
- Discontinuations due to adverse events were 12%, 16%, 22%, and 26% in placebo, 300 mg/d, 450 mg/d, and 600 mg/d respectively. The 450 and 600 mg/d groups were significantly different from placebo (P = 0001).
- Conclusions: Pregabalin at 300 mg/d, 450 mg/d, and 600 mg/d showed significantly greater response rates as compared to placebo although discontinuation rates for the 450 mg/d and 600 mg/d regimens were significantly higher as compared to placebo.
Classification
- Numerous classification systems proposed
- Yamaguchi’s criteria (J Rheumatol 1992;19:424-30) need 5 criteria to diagnose Still’s, at least 2 major
  - Major criteria
    - $T > 39^\circ C$, intermittent, > 1 wk
    - Typical rash
    - WBC > 10,000 (>80% granulocytes)
  - Minor criteria
    - Sore throat
    - Lymphadenopathy ± splenomegaly
    - Abnormal transaminases
    - Negative ANA and RF
  - Exclusion criteria: infection, malignancy, rheumatic disease

Investigations
- ANA and RF negative
- Markedly elevated ESR, CRP, ferritin (typically >1000 ng/mL, >2200 pmol/L)
  - Total ferritin >5 times ULN = 80% sensitive, 41% specific
- Anemia, thrombocytosis, leukocytosis may occur
- Transaminases, LDH may be elevated

Treatment
- 1st line therapy: methotrexate + low-dose glucocorticoids ± NSAIDs
- 2nd line therapy: other DMARDs (i.e. hydroxychloroquine, azathioprine, anti-IL1 and IL6 agents)

</tbody>
</table>

**Risks of Biologics:**
- Reactivation of TB or hepatitis B. Patients require negative TB skin test, chest x-ray and negative HBV serology prior to starting any of these medications
- Increased risk of serious infections
- Worsening heart failure

## Essential genito-urinary tract anatomy

- Figure 1. Midline cross-section of abdominal wall
- Figure 2. Anatomy of scrotum
- Figure 3. Essential genito-urinary tract anatomy

### Basic Anatomy Review

- Recall that the anatomical position of the penis is erect. Therefore, the anatomical ventral side of the penis appears to be the dorsal side of the flaccid penis.
Urologic History

- follow the OPQRSTUVW approach
  - note that pain may not be limited to the genital region (e.g., lower abdomen, CVA)
- inquire about risk factors: past urologic disease (e.g., UTI, stones, STI, cancers, anatomic abnormalities, family hx, medications, lifestyle factors, trauma, previous surgical procedures)
- constitutional symptoms: fever, chills, unintentional weight loss, night sweats, fatigue, malaise
- urinary output:
  - storage symptoms: frequency, nocturia, urgency, dysuria
  - voiding symptoms: straining, hesitancy, intermittency, post-void dribbling, reduced stream, feeling of incomplete voiding
  - hematuria: part of stream during which bleeding occurs, blood clots
  - incontinence: rushing to washroom (urge); leakage with coughing, sneezing, laughing (stress); constant dribbling (overflow)
- sexual function:
  - scrotal mass: see Scrotal Mass, U28
  - ED: see Erectile Dysfunction, U30
  - infertility: see Infertility, U34
- risk factors:
  - past urologic disease (e.g., UTI, stones, cancers, STI), anatomic abnormalities, trauma, previous surgical procedures, medications, family hx, lifestyle factors
- associated symptoms:
  - nausea/vomiting
- constitutional symptoms:
  - fever, chills, unintentional weight loss, night sweats, fatigue, malaise

Always ask about sexual function on history. Change in erectile function can be one of the first symptoms that there is concomitant coronary artery disease. If there is new onset ED, ask about chest pain with exertion.
Common Presenting Problems

Macroscopic (Gross) Hematuria

Definition
- blood in the urine that can be seen with the naked eye

Classification (see Nephrology, NP21)

Etiology

</tbody>
</table>

History
- if macroscopic, inquire about timing of hematuria in urinary stream
  - initial: anterior urethra
  - terminal: bladder neck and prostatic urethra
  - total: bladder and/or above

Investigations
- CBC (t/o anemia, leukocytosis), electrolytes, Cr, BUN
- urine studies:
  - U/A, C&S, cytology
- imaging:
  - CT (with contrast) has largely replaced IVP to investigate upper tracts (U/S alone is not sufficient)
  - cystoscopy to investigate lower tract (possible retrograde pyelogram)

Acute Management of Severe Bladder Hemorrhage
- manual irrigation via catheter with normal saline to remove clots
- CBI using large (22-26 Fr) 3-way Foley to help prevent clot formation
- cystoscopy if active bleeding:
  - identify resectable tumours
  - coagulate obvious sites of bleeding
- refractory bleeding:
  - continuous intravesical irrigation with 1% aluminum potassium sulfate solution as needed
  - intravesical instillation of 1% silver nitrate solution
  - intravesical instillation of 1-4% formalin (requires GA and pre-procedure cystogram to t/o reflux)
  - embolization or ligation of iliac arteries
  - cystectomy and diversion (rarely performed)

Upper Tract Imaging Options
- Intravenous Pyelogram (IVP): Traditional option but rarely used (replaced by CTU). Reasonable sensitivity for TCC, but poor sensitivity for RCC.
- U/S: Superior to IVP for evaluation of renal parenchyma and renal cysts. Limited sensitivity for TCC and small renal masses. U/S alone is not sufficient for upper tract imaging.
- CT Urogram (CTU): Optimal test for renal parenchyma, calculi, and infections. Involves exposure to radiation and IV contrast. Assess kidney function prior to use of contrast.
Microscopic Hematuria

Definition
• >2 RBCs/HPF on urinalysis of two separate samples

![Flowchart]

Figure 6. Workup of asymptomatic microscopic hematuria
Based on CUA Guidelines. AUA recommends cystoscopy and CT urogram for all patients with confirmed microscopic hematuria; follow-up for negative work-up is urinalysis yearly for two years, with repeat anatomic evaluation if microscopic hematuria persists

Dysuria

Definition
• painful urination

Etiology

Table 3. Differential Diagnosis of Dysuria

<table>
<thead>
<tr>
<th>Category</th>

</tr>
</tbody>
</table>

Investigations
• focused hx and P/E to determine cause (fever, D/C, conjunctivitis, CVA tenderness, back/joint pain)
  • any D/C (urethral, vaginal, cervical) should be sent for gonococcus/chlamydia testing; wet mount if vaginal D/C
  • U/A and urine C&S
  • if suspect infection, may start empiric ABx treatment (see Table 8 in Infectious and Inflammatory Disease, U11, for ABx)
  • ± imaging of urinary tract (tumour, stones)
Hydronephrosis

Definition
- dilation of the renal pelvis and calyces caused by the backward pressure of trapped urine

Etiology
- mechanical:
  - congenital: see Congenital Abnormalities, U36
  - acquired:
    - intrinsic: trauma, inflammation and bleeding, calculi, urologic neoplasms, BPH, urethral stricture, phimosis
    - extrinsic: trauma, neoplasms (uterine fibroid; colorectal, uterine, and cervical malignancies; lymphoma), aortic aneurysm, pregnancy (gravid uterus)
- functional:
  - neurogenic: neurogenic bladder, diabetic neuropathy, spinal cord disease
  - pharmacologic: anticholinergics, α-adrenergic agonists
  - hormonal: pregnancy (progesterone decreases ureteral tone)

Investigations
- focused hx, inquiring about pain (flank, lower abdomen, testes, labia), U/O, medication use, pregnancy, trauma, fever, hx of UTIs, calculi and PID
- CBC, electrolytes, Cr, BUN, U/A, C&S
- imaging studies (U/S is >90% sensitive and specific)

Treatment
- aimed at relieving the cause of obstruction/stasis
- urgent treatment is required if associated with infection, acute renal failure, or severe pain
  - percutaneous nephrostomy tube or ureteral stenting to relieve pressure

Voiding Dysfunction

- see Gynecology, GY34 for relevant female topics

Voiding

- two phases of lower urinary tract function:
  1. storage phase (bladder filling and urine storage):
     - accommodation and compliance
     - no involuntary contraction
  2. voiding phase (bladder emptying):
     - coordinated detrusor contraction
     - synchronous relaxation of outlet sphincters
     - no anatomic obstruction
- voiding dysfunction can therefore be classified as:
  - failure to store: due to bladder or outlet
  - failure to void: due to bladder or outlet
- three types of symptoms
  - storage (formerly known as irritative)
  - voiding (formerly known as obstructive)
  - post-voiding

Failure to Store: Urinary Incontinence

Definition
- involuntary leakage of urine

Etiology
- urgency incontinence:
  - detrusor overactivity:
    - CNS lesion, inflammation/infection (cystitis, stone, tumour), bladder neck obstruction (tumour, stone), BPH, idiopathic
  - decreased compliance of bladder wall:
    - CNS lesion, fibrosis
    - sphincter/urethral problem
Clinical Features
- stress urinary incontinence (SUI):
  - common in women; seen in men after prostate cancer treatment or pelvic operations
  - urethral hypermobility:
    - weakened pelvic floor and musculofascial urethral and vaginal supporting mechanisms
    - associated with childbirth, pelvic surgery, aging, levator muscle weakness
    - intrinsic sphincter deficiency (ISD): weakness of the urethra and associated smooth and striated muscle elements
    - pelvic surgery, neurologic problem, aging and hypoestrogen state
  - ISD and urethral hypermobility can co-exist
  - mixed incontinence:
    - combination of stress and urgency incontinence
  - overflow incontinence:
    - is a term sometimes used to describe urinary incontinence as a complication of urinary retention; for causes of urinary retention see Failure to Void: Urinary Retention, below
  - the International Continence Society no longer recommends the use of this term as it is confusing and lacks a clear definition; if the term is used it should be accompanied by the associated pathophysiology (e.g. BPH with overflow incontinence)

Epidemiology
- variable prevalence in women: 25-45%
- F:M = 2:1
- more frequent in the elderly, affecting 5-15% of those living in the community and 50% of nursing home residents

Clinical Features
- suprapubic pain
- palpable and/or percussible bladder (suprapubic)
- possible purulent/bloody meatal D/C
- increased size of prostate or reduced anal sphincter tone on DRE
- neurologic: presence of abnormal or absent deep tendon reflexes, reduced “anal wink”, saddle anesthesia
Investigations
• CBC, electrolytes, Cr, BUN, U/A and urine C&S, U/S, cystoscopy, urodynamic studies, PVR

Treatment
• treat underlying cause
• catheterization:
  ▪ acute retention
    • immediate catheterization to relieve retention; leave Foley in to drain bladder; F/U to
determine cause; closely monitor fluid status and electrolytes (risk of POD)
  ▪ chronic retention
    • intermittent catheterization by patient is commonly used; definitive treatment depends
on etiology
  ▪ suprapubic tube placement
  ▪ for post-operative patients with retention:
    ▪ encourage ambulation
    ▪ α-blockers to relax bladder neck outlet
    ▪ may need catheterization
    ▪ definitive treatment will depend on etiology

Benign Prostatic Hyperplasia (BPH)

Definition
• periurethral hyperplasia of stroma and epithelium in prostatic transition zone (see Figure 7)
• prostatic smooth muscle cells play a role in addition to hyperplasia

Etiology
• etiology unknown
  ▪ DHT required (converted from testosterone by 5-a reductase)
  ▪ possible role of impaired apoptosis, estrogens, other growth factors

Epidemiology
• age-related, extremely common (50% of 50 yr olds, 80% of 80 yr olds)
• 25% of men will require treatment

Clinical Features
• result from outlet obstruction and compensatory changes in detrusor function
• voiding symptoms:
  ▪ hesitancy, straining, weak/interrupted stream, incomplete bladder emptying
• storage symptoms:
  ▪ urgency, frequency, nocturia, urgency incontinence
  ▪ thought to be due to detrusor overactivity and/or decreased compliance
• DRE
  ▪ prostate is smooth, rubbery and symmetrically enlarged
• complications:
  ▪ retention
  ▪ overflow incontinence
  ▪ hydronephrosis
  ▪ infection
  ▪ gross hematuria
  ▪ bladder stones

Investigations
• hx, assessing LUTS and impact on QOL
  ▪ may include self-administered questionnaires (IPSS or AUA symptom index for severity,
progression, and treatment response)
• P/E, including DRE
• U/A to exclude UTI
• Cr ± renal U/S to assess for hydronephrosis
• PSA to t/o malignancy (see CaP Screening, U25)
• uroflowmetry to measure flow rate (optional)
• PVR (optional)
• cystoscopy prior to potential surgical management
• biopsy if suspicious for malignancy

Patients with ascites may have a falsely elevated PVR measured by bladder scan.

Figure 7. Cross-section of prostate

Approximate Prostate Sizes
• 20 cc – chestnut
• 25 cc – plum
• 50 cc – lemon
• 75 cc – orange
• 100 cc – grapefruit

AUA Prostate Symptom Score

FUNWISE
F = Frequency
U = Urgency
N = Nocturia
W = Weak stream
I = Intermittency
S = Straining
E = Emptying, incomplete feeling of

Each symptom graded out of 5
0-7: Mildly symptomatic
8-19: Moderately symptomatic
20-35: Severely symptomatic

Note: dysuria not included in score but is commonly associated with BPH
Treatment

Table 6. Treatment of BPH

<table>
<thead>
<tr>
<th>When to use</th>
<th>Conservative</th>
<th>Medical</th>
<th>Surgical</th>
<th>Minimally Invasive Surgical Therapies</th>
</tr>
</thead>
<tbody>
<tr>
<td>All patients</td>
<td>Moderate to severe symptoms</td>
<td>Moderate to severe symptoms</td>
<td>Patients who wish to avoid or may not tolerate surgery</td>
<td></td>
</tr>
</tbody>
</table>

Options
- Watchful waiting: 50% of patients improve spontaneously
- Lifestyle modifications (e.g. evening fluid restriction, planned voiding)
- \(\alpha\)-adrenergic antagonists: reduce stromal smooth muscle tone
- 5-\(\alpha\) reductase inhibitor: block conversion of testosterone to DHT, act to reduce prostate size
- Combination is synergistic
- Anti-cholinergic agents (for storage LUTS, without elevated PVR)
- TURP (see U42)
- Laser ablation
- TUIP (prostate <30 g)
- Open prostatectomy
- Microwave therapy
- TUNA
- Prostatic stent

Urethral Stricture

Definition
- Decrease in urethral calibre due to scar formation in urethra (may also involve corpus spongiosum)
- M>F

Etiology
- Congenital
  - Failure of normal canalization (technically not a stricture)
- Trauma:
  - Instrumentation/catheterization (most common)
  - External trauma (e.g. burns, straddle injury)
- Foreign body
- Infection:
  - Long-term indwelling catheter
  - STI
- Inflammation:
  - Balanitis xerotica obliterans (lichen sclerosis or chronic progressive sclerosing dermatosis of the male genitalia) causing meatal stenosis

Clinical Features
- Voiding symptoms
- Urinary retention
- Hydronephrosis
- Related infections: recurrent UTI, secondary prostatitis/epididymitis

Investigations
- Laboratory findings:
  - Flow rates <10 mL/s (normal ~20 mL/s) on uroflowmetry
  - Urine culture usually negative, but U/A may show pyuria
- Radiologic findings:
  - RUG and VCU will demonstrate location
  - Cystoscopy

Treatment
- Urethral dilatation:
  - Temporarily increases lumen size by breaking up scar tissue
  - Healing will often reform scar tissue and recreate stricture
- Visual internal urethrotomy (VIU):
  - Endoscopically incise stricture
  - Cure rate 50-80% with single treatment, <50% with repeated courses
- Open surgical reconstruction:
  - Complete stricture excision with anastomosis, \(\pm\) urethroplasty depending on location and size of stricture
Neurogenic Bladder

Definition
• malfunctioning urinary bladder due to deficiency in some aspect of its innervation

Neurophysiology

Table 7. Efferent Sympathetic, Parasympathetic, and Somatic Nerve Supply

<td>Detrusor</td>
</tr>
</tbody>
</table>

• stretch receptors in the bladder wall relay information to PMC and activate micturition reflex (normally inhibited by cortical input)
  ▪ micturition:
    ▪ stimulation of parasympathetic neurons (bladder contraction)
    ▪ inhibition of sympathetic and somatic neurons (internal and external sphincter relaxation, respectively)
  ▪ urine storage:
    ▪ opposite of micturition
• voluntary action of external sphincter ( pudendal nerve roots S2-S4) can inhibit urge to urinate
• cerebellum, basal ganglia, thalamus, and hypothalamus all have input at PMC in the brainstem

Classification of Neurologic Voiding Dysfunction
• neurogenic detrusor overactivity (formerly termed detrusor hyperreflexia):
  ▪ lesion above PMC (e.g. stroke, tumour, MS, Parkinson’s disease)
  ▪ loss of voluntary inhibition of voiding
  ▪ intact pathway inferior to PMC maintains coordination of bladder and sphincter
• detrusor sphincter dyssynergia (DSD):
  ▪ lesion of spinal cord (e.g. trauma, MS, arteriovenous malformation, transverse myelitis)
  ▪ loss of coordination between detrusor and sphincter (detrusor contracts on closed sphincter and vice versa)
  ▪ component of detrusor overactivity as well
• detrusor atony/areflexia:
  ▪ lesion of sacral cord or peripheral efferents (e.g. trauma, DM, disc herniation, MS, congenital spinal cord abnormality)
  ▪ flaccid bladder which fails to contract
  ▪ may progress to poorly compliant bladder with high pressures
• peripheral autonomic neuropathy:
  ▪ deficient bladder sensation → increasing residual urine → decompensation (e.g. DM, neurosyphilis, herpes zoster)
• muscular lesion:
  ▪ can involve detrusor, smooth/ striated sphincter

Neuro-Urologic Evaluation
• hx and P/E (urologic and general neurologic)
• U/A, renal profile
• imaging
  ▪ IVP (less used), U/S to r/o hydronephrosis and stones
• cystoscopy
• urodynamic studies:
  ▪ uroflowmetry to assess flow rate, pattern
  ▪ filling CMG to assess capacity, compliance, detrusor overactivity
  ▪ voiding CMG (pressure-flow study) to assess bladder contractility and extent of bladder outflow obstruction
  ▪ video study to visualize bladder/bladder neck/urethra during CMG using x-ray contrast
  ▪ EMG ascertains presence of coordinated or uncoordinated voiding, allows accurate diagnosis of DSD

Treatment
• goals of treatment:
  ▪ prevent renal failure
  ▪ prevent infections
  ▪ achieve social continence
• treatment options depend on status of bladder and urethra
  ▪ bladder hyperactivity → medications to relax bladder (see Urinary Incontinence, U6)
    • if refractory:
      – botulinum toxin injections into bladder wall
      – occasionally augmentation cystoplasty (enlarging bladder volume and improving compliance by grafting section of detubularized bowel onto the bladder)
      – occasionally urinary diversion (ileal conduit or continent diversion) if bladder management unsuccessful
  ▪ flaccid bladder → CIC

**Autonomic Dysreflexia**

• occurs in patients with spinal cord injury above T6/T7
• exaggerated sympathetic nervous system response to visceral stimulation below the lesion
• stimulation includes instrumentation or distension of bladder, urethra, or rectum
• symptoms include HTN, headache, reflex bradycardia, sweating, anxiety, piloerection
• vasoconstriction below lesion, vasodilation above lesion
• treatment: removal of noxious stimuli, parenteral ganglionic or α-blockers, nifedipine (prophylaxis during cystoscopy)

**Post-Obstructive Diuresis (POD)**

**Definition**

• polyuria resulting from relief of severe chronic obstruction
• >3 L/24 h or >200 cc/h over each of two consecutive hours

**Pathophysiology**

• physiologic POD secondary to excretion of retained urea, Na+, and H2O (high osmotic load) after relief of obstruction
  • self-limiting; usually resolves in 48 h with PO fluids but may persist to pathologic POD
• pathologic POD is a Na+-wasting nephropathy secondary to impaired concentrating ability of the renal tubules due to:
  ▪ decreased reabsorption of NaCl in the thick ascending limb and urea in the collecting tubule
  ▪ increased medullary blood flow (solute washout)
  ▪ increased flow and solute concentration in the distal nephrons

**Management**

• admit patient and closely monitor hemodynamic status and electrolytes (Na+ and K+ q6-12h and replace prn; follow Cr and BUN to baseline)
• monitor U/O q2h and ensure total fluid intake <U/O by replacing every 1 cc U/O with 0.5 cc 1/2 NS IV (PO fluids if physiologic POD)
• avoid glucose-containing fluid replacement (iatrogenic diuresis)

**Infectious and Inflammatory Diseases**

Urinary Tract Infection (UTI)

- for UTIs during pregnancy, see Obstetrics, OB20

Definition
- symptoms suggestive of UTI (see Clinical Features below) + evidence of pyuria and bacteriuria on U/A or urine C&S
  - if asymptomatic + 100,000 CFU/mL = asymptomatic bacteriuria; only requires treatment in certain patients (e.g. pregnancy)

Classification
- uncomplicated: lower UTI in a setting of functionally and structurally normal urinary tract
- complicated: structural and/or functional abnormality, immunocompromised, iatrogenic complication, pregnancy, pyelonephritis, catheter-associated
- recurrent: see Recurrent/Chronic Cystitis, U13

Risk Factors
- stasis and obstruction:
  - residual urine due to impaired urine flow e.g. PUVs, reflux, medication, BPH, urethral stricture, cystocele, neurogenic bladder
- foreign body:
  - introduce pathogen or act as nidus of infection e.g. catheter, instrumentation
- decreased resistance to organisms:
  - DM, malignancy, immunosuppression, spermicide use, estrogen depletion, antimicrobial use
- other factors:
  - trauma, anatomic abnormalities, female, sexual activity, fecal incontinence

Clinical Features
- storage symptoms: frequency, urgency, dysuria
- voiding symptoms: hesitancy, post-void dribbling
- other: suprapubic pain, hematuria, foul-smelling urine
- pyelonephritis – if present: typically presents with more severe symptoms (e.g. fever/chills, CVA tenderness, flank pain)

Organisms
- typical organisms (see sidebar)
- atypical organisms:
  - tuberculosis (TB)
  - Chlamydia trachomatis
  - Mycoplasma (Ureaplasma urealyticum)
  - fungi (Candida)

Indications for Investigations
- pyelonephritis
- persistence of pyuria/symptoms following adequate therapy
- severe infection with an increase in Cr
- recurrent/persistent infections
- atypical pathogens (urea splitting organisms)
- hx of structural abnormalities/decreased flow

Antibiotic therapy should always be based on local resistance patterns and adjusted according to culture and sensitivity results.

IV antibiotics should be stepped down to oral when the patient is afebrile and clinically stable.

Acute uncomplicated pyelonephritis: suspected or confirmed enterococcus infection requires treatment with ampicillin.
Investigations
- U/A, urine C&S
  - UA: leukocytes ± nitrites ± hematuria
  - C&S: midstream, catheterized, or suprapubic aspirate
- if hematuria present, retest post-treatment, if persistent need hematuria workup (see Microscopic Hematuria, U5)
- CT scan if indicated

Treatment
- see Table 8 for approach to ABx therapy
- if febrile, consider admission with IV therapy and r/o obstruction

Recurrent/Chronic Cystitis

Definition
- ≥3 UTIs/12 mo

Etiology
- bacterial reinfection (80%) vs bacterial persistence (relapse)
  - bacterial reinfection:
    - recurrence of infection with either 1) a different organism, 2) the same organism if cultured >2 wk following therapy, or 3) with any organism with an intermittent sterile culture
  - bacterial persistence:
    - same organism cultured within 2 wk of sensitivity-based therapy

Investigations
- assess predisposing factors as described above
- investigations may include cystoscopy, U/S, CT

Treatment
- lifestyle changes (limit caffeine intake, increase fluid/H2O intake)
- ABx: continuous vs. post-coital (see Table 8)
- post-menopausal women: consider topical or systemic estrogen therapy
- no treatment for asymptomatic bacteriuria except in pregnant women or patients undergoing urinary tract instrumentation

Interstitial Cystitis
(Painful Bladder or Bladder Pain Syndrome)

Definition
- chronic urgency, frequency ± pain without other reasonable causation

Classification
- non-ulcerative (more common)
- ulcerative

Etiology
- unknown
  - theories: increased epithelial permeability, autoimmune, neurogenic, defective glycosaminoglycan (GAG) layer overlying mucosa
  - associations: severe allergies, IBS, fibromyalgia

Epidemiology
- prevalence: 20/100,000
- 90% of cases are in females
- mean age at onset is 40 yr (non-ulcerative tends to affect a younger to middle-aged population, while ulcerative tends to be seen in middle-aged to older)

Clinical Features
- pain associated with the bladder
- glomerulations (submucosal petechiae) or Hunner’s ulcers on cystoscopic examination
- urinary urgency
- negative U/A, urine C&S, and urine cytology

Differential Diagnosis
- UTI, vaginitis, bladder tumour
- radiation/chemical cystitis
- eosinophilic/TB cystitis
- bladder calculi

Prevention of UTIs
- Maintain good hydration (especially with cranberry juice)
- Wipe from front to back to avoid contamination of the urethra with feces from the rectum
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse

Cystoscopic evaluation is not necessary to make a diagnosis.
Treatment
• first-line: patient empowerment (diet, lifestyle, stress management), pain management
• second-line:
  ▪ oral: pentosan polysulfate sodium, amitriptyline, cimetidine, hydroxyzine
  ▪ intravesical: dimethylsulfoxide (DMSO), heparin, lidocaine
• third-line: cystoscopy with bladder hydrodistention (traditionally diagnostic) under GA, treat Hunner’s ulcers if present
• other: neuromodulation, cyclosporine A, intradetrusor botulinum toxin
• surgery (last resort): augmentation cystoplasty, or urinary diversion ± cystectomy

Acute Pyelonephritis

Definition
• infection of the renal parenchyma with local and systemic manifestations

Etiology
• ascending (usually GN bacilli) or hematogenous route (usually GP cocci)
• causative microorganisms:
  ▪ gram positives: *Enterococcus faecalis, S. aureus, S. saprophyticus*
  ▪ gram negatives: *E. coli* (most common), *Klebsiella, Proteus, Pseudomonas, Enterobacter*
• common underlying causes of pyelonephritis
  ▪ stones, strictures, prostatic obstruction, vesicoureteric reflux, neurogenic bladder, catheters, DM, sickle-cell disease, PCKD, immunosuppression, post-renal transplant, instrumentation, pregnancy

Clinical Features
• rapid onset (<24 h)
• LUTS including frequency, urgency, hematuria; NOT dysuria unless concurrent cystitis
• fever, chills, nausea, vomiting, myalgia, malaise
• CVA tenderness or exquisite flank pain

Investigations
• U/A, urine C&S
• CBC and differential: leukocytosis, left shift
• imaging indicated if suspicious of complicated pyelonephritis or symptoms do not improve with 48-72 h of treatment
  ▪ abdominal/pelvic U/S
  ▪ CT
• nuclear medicine: DMSA scan can be used to help secure the diagnosis
  ▪ a photopenic defect indicates active infection or scar; if normal alternative diagnoses should be considered

Treatment
• hemodynamically stable:
  ▪ outpatient oral ABx treatment ± single initial IV dose (see Table 8)
• severe or non-resolving:
  ▪ admit, hydrate, and treat with IV ABx (see Table 8)
• emphysematous pyelonephritis:
  ▪ consider emergent nephrectomy after IV ABx started and patient stabilized
• renal obstruction:
  ▪ admit for emergent stenting or percutaneous nephrostomy tube

Prostatitis/Prostatodynia

Epidemiology
• most common urologic diagnosis in men <50 yr
• prevalence 2-12%
Classification

*NIH-CPSI: National Institute of Health Chronic Prostatitis Symptom Index

Epididymitis and Orchitis

**Etiology**
- common infectious causes:
  - <35 yr: N. gonorrheae or Chlamydia trachomatis
  - ≥35 yr or penetrative anal intercourse: GI organisms (especially E. coli)
- other causes:
  - mumps infection may involve orchitis, post-parotitis
  - TB
  - syphilis
  - granulomatous (autoimmune) in elderly men
  - amiodarone (involves only head of epididymis)

**Risk Factors**
- UTI
- unprotected sexual contact
- instrumentation/catheterization
- reflux
- increased pressure in prostatic urethra (straining, voiding, heavy lifting) may cause reflux of urine along vas deferens → sterile epididymitis
- immunocompromise

**Clinical Features**
- sudden onset scrotal pain and swelling ± radiation along cord to flank
- scrotal erythema and tenderness
- fever
- storage symptoms, purulent D/C
- reactive hydrocele

**Investigations**
- U/A, urine C&S
- ± urethral D/C: Gram stain/culture
- if diagnosis uncertain, must do:
  - colour-flow Doppler U/S to r/o testicular torsion

**Treatment**
- r/o torsion (see Investigations and Table 23, U28)
- see Table 8 for ABx therapy
- scrotal support, bed rest, ice, analgesia

**Complications**
- if severe → testicular atrophy
- 30% have persistent infertility problems

Prehn’s sign: pain may be relieved with elevation of testicles in epididymitis but not in testicular torsion. Poor sensitivity, especially in children.

If unsure between diagnoses of epididymitis and torsion, always go to OR. Remember: torsion >6 h has poor prognosis

Inadequately treated acute epididymitis may lead to chronic epididymitis or epididymo-orchitis.
Urethritis

Etiology
• infectious or inflammatory (e.g. reactive arthritis)

Stone Disease

Epidemiology
• prevalence of 2-3%
• male:female = 3:1
• peak incidence 30-50 yr of age
• recurrence rate: 10% at one yr, 50% at 5 yr, 60-80% lifetime

Risk Factors
• hereditary: RTA, G6PD, cystinuria, xanthinuria, oxaluria, etc.
• lifestyle: minimal fluid intake; excess vitamin C, oxalate, purines, calcium
• medications: loop diuretics (furosemide, bumetanide), acetazolamide, topiramate, and zonisamide
• medical conditions: UTI (with urea-splitting organisms), myeloproliferative disorders, IBD, gout, DM, hypercalcemia disorders (hyperparathyroidism, tumour lysis syndrome, sarcoidosis, histoplasmosis), obesity (BMI > 30)

Clinical Features
• urinary obstruction → upstream distention → pain
  ▪ flank pain from renal capsular distention (non-colicky)
  ▪ severe waxing and waning pain radiating from flank to groin, testis, or tip of penis due to stretching of collecting system or ureter (ureteral colic)
• writhing, never comfortable, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
• occasionally symptoms of trigonal irritation (frequency, urgency)
• bladder stones result in: storage and voiding LUTS, terminal hematuria, suprapubic pain
• if fever, r/o concurrent pyelonephritis and/or obstruction

</table>

Location of Stones
• calyx: may cause flank discomfort, persistent infection, persistent hematuria, or remain asymptomatic
• pelvis tend to cause obstruction at UPJ, may cause persistent infection
• ureter: <5 mm diameter will pass spontaneously in 75% of patients

Stone Pathogenesis
• supersaturation of stone constituents (at appropriate temperature and pH)
• stasis, low flow, and low volume of urine (dehydration)
• crystal formation and stone nidus
• loss of inhibitory factors:
  ▪ citrate (forms soluble complex with calcium)
  ▪ magnesium (forms soluble complex with oxalate)
  ▪ pyrophosphate
  ▪ Tamm-Horsfall glycoprotein

</tr>
</tbody>
</table>

Treatment – Acute

- medical
  - analgesic ± antiemetic
  - NSAIDs help lower intra-ureteral pressure
  - medical expulsions therapy (MET)
    - α-blockers: increase rate of spontaneous passage in distal ureteral stones
    - calcium channel blockers
  - ± Abx for bacteriuria
  - IV fluids if vomiting (note: IV fluids do not promote stone passage)
- interventional:
  - required if obstruction endangers patient, e.g. sepsis, renal failure
  - first line: ureteric stent (via cystoscopy)
  - second line: image-guided percutaneous nephrostomy
- admit if necessary:
  - see sidebar: Indications for Admission to Hospital

Treatment – Elective

- medical:
  - likely conservative if ureteral stone <10 mm or kidney stone <5 mm and no complications/symptoms well controlled
  - stones <5 mm especially likely to pass spontaneously
  - PO fluids to increase urine volume to >2 L/d (3-4 L if cystine) and MET
  - specific to stone type (see Table 13)
  - periodic imaging to monitor stone position and assess for hydronephrosis
  - progress to interventional stone removal methods if symptoms worsen or fail to improve (indicating stone passage)

Efficacy of α-Blockers for the Treatment of Ureteral Stones

J. Urol. 2007;177:983-987

Study: Meta-analysis of prospective randomized trials comparing α-blockers to conservative therapy.

Methods: MEDLINE, the Cochrane Central Search library, EMBASE, and the electronic database of abstracts presented at the Annual Meeting of the American Urological Association were searched for literature published in English. 11 studies met selection criteria (n=911). Treatment ranged from 8 d-6 wk. Outcome of interest was incidence of distal ureteral stone expulsion.

Results: Administration of an α-blocker with conservative therapy increases incidence of stone expulsion over conservative treatment alone by 44% (95% CI 1.31-1.59, p<0.001).

Conclusion: α-blocker therapy is associated with significantly increased rates of distal ureteral stone expulsion.

Indications for Admission to Hospital:
- Intractable pain
- Intractable vomiting
- Fever (suggests infection)
- Compromised renal function (including single kidney, bilateral obstructing stone)
- Pregnancy

Stones and Infection

If septic, urgent decompression via ureteric stent or percutaneous nephrostomy is indicated. Definitive treatment of the stone should be delayed until the sepsis has cleared.

Although hypercalciuria is a risk factor for stone formation, decreasing dietary calcium is NOT recommended to prevent stone formation. Low dietary calcium leads to increased GI oxalate absorption and higher urine levels of calcium oxalate.
interventional:
- kidney
  - may stent prior to ESWL if stone is 1.5-2.5 cm
  - ESWL if stone <2 cm
  - PCNL if stone >2 cm (see sidebar)
- ureteral stones >10 mm
  - ESWL and URS are both first line treatment modalities for all locations
    - URS has significantly greater stone-free rates for stones at all locations in ureter, but also has higher complication rates (ureter perforation, stricture formation, etc.)
  - PCNL is second line treatment
- laparoscopic or open stone removal (very rare)
- bladder
  - transurethral stone removal or cystolitholapaxy
  - remove outflow obstruction (TURP or stricture dilatation)

Prevention
- dietary modification:
  - increase fluid (>2 L/d), K+ intake
  - reduce animal protein, oxalate, Na+, sucrose, and fructose intake
  - avoid high-dose vitamin C supplements
- medications:
  - thiazide diuretics for hypercalciuria
  - allopurinol for hyperuricosuria
  - potassium citrate for hypocitraturia, hyperuricosuria

Table 13. Stone Classification

<table>

Urological Neoplasms

Approach to Renal Mass

Figure 9. Workup of a renal mass

*Imaging modality may be different in cases of contrast allergy or elevated creatinine

Benign Renal Neoplasms

CYSTIC KIDNEY DISEASE
- simple cysts: usually solitary or unilateral
  - very common: up to 50% at age 50
  - usually incidental finding on abdominal imaging
  - Bosniak Classification is used to stratify for risk of malignancy based on cyst features from contrast CT (see Table 14)
- polycystic kidney disease
  - autosomal recessive: multiple bilateral cysts, often leading to early renal failure in infants
  - autosomal dominant: progressive bilateral disease leading to HTN and renal failure
- medullary sponge kidney: cystic dilatation of the collecting ducts
  - usually benign course, but patients are predisposed to stone disease
- von Hippel-Lindau syndrome: multiple bilateral cysts or clear cell carcinomas (50% incidence of RCC)
  - renal cysts, cerebellar, spinal and retinal hemangioblastomas, pancreatic and epididymal cysts, pheochromocytomas

Malignant Renal Neoplasms

RENAL CELL CARCINOMA (RCC)

**Etiology**
- cause unknown
- originates from proximal convoluted tubule epithelial cells in clear cell subtype (most common)
- hereditary forms seen with von Hippel-Lindau syndrome and hereditary papillary renal carcinoma

**Epidemiology**
- 8th most common malignancy (accounts for 3% of all newly diagnosed cancers)
- 85% of primary malignant tumours in kidney
- male:female = 3:2
- peak incidence at 50-60 yr of age

**Pathology**
- histological subtypes: clear cell (75-85%), papillary (10-15%), chromophobic (5-10%), collecting duct
- sarcomatoid elements in any subtype is a poor prognostic factor

**Risk Factors**
- top 3 risk factors: smoking, HTN, obesity
- miscellaneous: horseshoe kidney, acquired renal cystic disease

**Clinical Features**
- usually asymptomatic: frequently diagnosed incidentally by U/S or CT
- poor prognostic indicators: weight loss, weakness, anemia, bone pain
- classic “too late triad” found in 10-15%:
  - gross hematuria 50%  
  - flank pain <50%
  - palpable mass <30%
- was called the “internist’s tumour” because of paraneoplastic symptomatology (see sidebar) – now called the “radiologist’s tumour” because of incidental diagnosis via imaging
- metastases: seen in 1/3rd of new cases; additional 20-40% will go on to develop metastases
  - bone, brain, lung and liver most common sites

**Investigations**
- routine labs for paraneoplastic syndromes (CBC, ESR, LFTs, extended electrolytes)
- U/A (60-75% have hematuria)
- renal U/S: solid vs. cystic lesion
- CT: higher sensitivity than U/S for detection of renal masses and for staging purposes
- MRI: useful for evaluation of vascular extension
- FNA: to confirm diagnosis if considering observation or other non-surgical therapy

**Staging**
- involves CT, CXR, liver enzymes and LFTs, bone scan

RCC Systemic Effects: paraneoplastic syndromes (10-40% of patients)
- Hematopoietic disturbances: anemia, polycythemia, raised ESR
- Endocrinopathies: hypercalcemia (increased vitamin D hydroxylation), erythrocytosis (increased erythropoietin), HTN (increased renin), production of other hormones (prolactin, gonadotropins, TSH, insulin, and cortisol)
- Hepatic cell dysfunction or Stauffer syndrome: abnormal LFTs, decreased WBC count, fever, areas of hepatic necrosis; no evidence of metastases; reversible following removal of primary tumour
- Hemodynamic alterations: systolic HTN (due to AV shunting), peripheral edema (due to caval obstruction)

</tbody>
</table>

Treatment

- surgical
  - radical nephrectomy: en bloc removal of kidney, tumour, ipsilateral adrenal gland (in upper pole tumours) and intact Gerota’s capsule and paraaortic lymphadenectomy
  - partial nephrectomy (parenchyma-sparing): <4 cm tumour or solitary kidney/bilateral tumours
  - surgical removal of solitary metastasis may be considered
- ablative techniques (cryoablation, RFA)
- palliative radiation to painful bony lesions
- therapy for advanced stage:
  - anti-angiogenesis/anti-VEGF (e.g. bevacizumab)
  - mTOR inhibitors (e.g. temsirolimus, everolimus)
  - high-dose IL-2 (high toxicity but able to induce long-term remission in 10% of patients)
  - IFN α: monotherapy has been largely replaced by molecularly targeted agents listed above
- tyrosine kinase inhibitors for metastatic disease (e.g. sunitinib, sorafenib)

Prognosis

- stage at diagnosis most important prognostic factor:
  - T1: 90-100% 5-yr survival
  - T2-T3: 60% 5-yr survival
  - metastatic disease: <5% 10-yr survival

Carcinoma of the Renal Pelvis and Ureter

Etiology

- risk factors include:
  - smoking
  - chemicals/dietary exposures (industrial dyes and solvents; aristolochic acid)
  - analgesic abuse (acetaminophen, ASA, and phenacetin)
  - Balkan nephropathy

Epidemiology

- rare: accounts for 5% of all urothelial cancers
- frequently multifocal, 2-5% are bilateral
- M:F = 3:1
- relative incidence: bladder:renal:ureter = 100:10:1

Pathology

- 85% are papillary urothelial carcinoma (TCC); others include SCC and adenocarcinoma
- TCC of ureter and renal pelvis are histologically similar to bladder TCC

Clinical Features

- gross/microscopic hematuria
- flank pain
- storage or voiding symptoms (dysuria only if lower urinary tract involved)
- flank mass ± hydronephrosis (10-20%)

Investigations

- IVP/CT urogram
- cystoscopy and retrograde pyelogram

Treatment

- radical nephroureterectomy with cuff of bladder
- distal ureterectomy for distal ureteral tumours

Differential Diagnosis of Filling Defect

- Urothelial cell carcinoma (differentiate via cytology and CT scan)
- Uric acid stone (differentiate via cytology and CT scan)
- Blood clot
- Pyelitis cystica
- Papillary necrosis
- Fungus ball
- Gas bubble from gas producing organisms

Sorafenib in Advanced Clear-Cell Renal Cell Carcinoma – TARGET Trial

NEJM 2007;356:125-134

Study: Phase III, double-blind RCT comparing multikinase inhibitor, sorafenib, with placebo in treatment of advanced clear-cell renal cell carcinoma.

Methods: Patients with clear cell renal cell carcinoma, resistant to standard therapy. The main intervention and outcome were sorafenib and overall survival, respectively.

Results: Progression-free survival in intervention group was 5.5 mo, compared with 2.8 mo in the placebo group. The survival improvement was associated with an increased number of adverse events.
Bladder Carcinoma

Etiology
- unknown, but environmental risk factors include:
  - smoking (main factor – implicated in 60% of new cases)
  - aromatic amines: naphthylamines, benzidine, tryptophan, phenacetin metabolites
  - cyclophosphamide
  - prior hx of radiation treatment to the pelvis
  - *Schistosoma hematobium* infection (associated with SCC)
  - chronic irritation: cystitis, chronic catheterization, bladder stones (associated with SCC)

Epidemiology
- 2nd most common urological malignancy
- male:female = 3:1, white:black = 4:1
- mean age at diagnosis is 65 yr

Pathology
- classification:
  - TCC >90%
  - SCC 5-7%
  - adenocarcinoma 1%
  - others <1%
- stages and prognoses of urothelial carcinoma at diagnosis:
  - non-muscle invasive (75%) → >80% overall survival
  - 15% of these will progress to invasive TCC
  - the majority of these patients will have recurrence
  - invasive (25%) → 50-60% 5-yr survival
  - 85% have no prior hx of superficial TCC (i.e. de novo)
  - 50% have occult metastases at diagnosis, and most of these will develop overt clinical evidence of metastases within 1 yr – lymph nodes, lung, peritoneum, liver
- carcinoma in situ → flat, non-papillary erythematous lesion characterized by dysplasia confined to urothelium
  - more aggressive, worse prognosis
  - usually multifocal
  - may progress to invasive TCC

Clinical Features
- asymptomatic (20%)
- hematuria (key symptom: 85-90% at the time of diagnosis)
- pain (50%) → location determined by size/extent of tumour (i.e. flank, suprapubic, perineal, abdominal, etc.)
- clot retention (17%)
- storage urinary symptoms → consider carcinoma in situ
- palpable mass on bimanual exam → likely muscle invasion
- obstruction of ureters → hydronephrosis and uremia (nausea, vomiting, and diarrhea)

Investigations
- U/A, urine C&S, urine cytology
- U/S
- CT scan with contrast or IVP → look for filling defect
- cystoscopy with bladder washings (gold standard)
- biopsy to establish diagnosis and to determine depth of penetration
- specific bladder tumour markers (e.g. NMP-22, BTA, Immunocyt, FDP)

Grading
- Grade 1: well-differentiated (10% invasive)
- Grade 2: moderately differentiated (50% invasive)
- Grade 3: poorly differentiated (80% invasive)

Staging
- for invasive disease: CT or MRI, CXR, LFTs, extended electrolytes (metastatic work-up)
Table 17. 2010 TNM Classification of Bladder Carcinoma (see Figure 11)

Figure 11. Urothelial carcinoma of bladder

Treatment
- superficial (non-muscle invasive) disease: Tis, Ta, T1
  - TURBT ± single dose or 6-wk course of intravesical chemo/immuno-therapy (e.g. BCG, mitomycin C) to decrease recurrence rate
  - maintenance with intravesical chemotherapy with BCG may be continued for 2-3 yr
  - high grade disease: TURBT + maintenance BCG OR cystectomy in select patients
- invasive disease: T2a, T2b, T3
  - radical cystectomy + pelvic lymphadenectomy with urinary diversion (e.g. ileal conduit, Indiana pouch, ileal neobladder) or TURBT + chemo-radiation for small tumours
  - neo-adjuvant chemotherapy prior to cystectomy may also be done
  - use of adjuvant chemotherapy after definitive local treatment is controversial
- advanced/metastatic disease: T4a, T4b, N+, M+
  - initial combination of systemic chemotherapy ± irradiation ± surgery

Prognosis
- depends on stage, grade, size, number of lesions, recurrence and presence of CIS:
  - T1: 90% 5-yr survival
  - T2: 55% 5-yr survival
  - T3: 20% 5-yr survival
  - T4/N+/M+: <5% 5-yr survival

Prostatic Carcinoma (CaP)

Etiology
- not known
- risk factors
  - increased incidence in persons of African descent
  - high dietary fat = 2x risk
  - family hx
    - 1st degree relative = 2x risk
    - 1st and 2nd degree relatives = 9x risk

Epidemiology
- most prevalent cancer in males
- 3rd leading cause of male cancer deaths (following lung and colon)
- up to 50% risk of CaP at age 50
- lifetime risk of death from CaP is 3%
- 75% diagnosed between ages of 60 and 85; mean age at diagnosis is 72
Pathology
- adenocarcinoma
  - >95%, often multifocal
- urothelial carcinoma (4.5%)
  - associated with TCC of bladder; does NOT follow TNM staging below; not hormone-responsive
- endometrial (rare)
  - carcinoma of the utricle

Anatomy (see Figure 7)
- 60-70% of nodules arise in the peripheral zone
- 10-20% arise in the transition zone
- 5-10% arise in the central zone

Clinical Features
- usually asymptomatic
- most commonly detected by DRE, elevated PSA, or as an incidental finding on TURP
  - DRE: hard irregular nodule or diffuse dense induration involving one or both lobes
  - PSA: see CaP Screening, U25
- locally advanced disease
  - storage and voiding symptoms, ED (all uncommon without spread)
- metastatic disease:
  - bony mets to axial skeleton common
  - visceral mets are less common (liver, lung, and adrenal gland most common sites)
  - leg pain and edema with nodal mets obstructing lymphatic and venous drainage

Methods of Spread
- local invasion
- lymphatic spread to regional nodes
  - obturator > iliac > presacral/para-aortic
- hematogenous dissemination occurs early

Investigations
- DRE
- PSA elevated in the majority of patients with CaP
- TRUS-guided needle biopsy
- bone scan may be omitted in untreated CaP with PSA <10 ng/mL
- CT scanning to assess metastases
- MRI: being investigated for possible role in detection, staging, MRI-guided biopsying and active surveillance

Costs:
- Medicare reimbursement for medical care.
- Weigh the costs and benefits of different treatment options.
- Consider the long-term consequences of treatment.

U25 Urology Urological Neoplasms Toronto Notes 2014

Radical Prostatectomy versus Watchful Waiting in Early Prostate Cancer (Scandinavian Prostate Cancer Group Study)
NEJM 2012;367:1708-1717
Study: Randomized clinical trial comparing surgical treatment with radical prostatectomy for localized prostate cancer.
Methods: 695 men from 14 centres in Finland, Sweden, and Iceland with newly diagnosed, localized prostate cancer were included in this study.
Main outcomes: Mortality, distant metastases, local progression.
Results: For men with low-risk prostate cancer (PSA<10, Gleason score<7), at 15 yr after treatment initiation, the relative risk of death due to prostate cancer in the radical prostatectomy group was 0.82 (p<0.01). The cumulative incidence of death from prostate cancer after radical prostatectomy was high as compared with other studies.
Conclusions: Radical prostatectomy was associated with reduced rate of death due to prostate cancer.

Radical Prostatectomy versus Observation for Localized Prostate Cancer. (Prostate Cancer Intervention versus Observation Trial (PIVOT) Study Group)
NEJM 2012;367:203-213
Study: Randomized clinical trial comparing observation with radical prostatectomy for localized prostate cancer.
Methods: 731 men at 52 United States centres with localized prostate cancer participated.
Main outcomes: Mortality, bone metastases, surgical morbidity.
Results: Radical prostatectomy did not reduce all-cause or prostate cancer mortality relative to observation (relative risk 0.80, p<0.09), through at least 12 yr of follow-up.
Conclusions: Observation is recommended for localized prostate cancer, especially in men with low PSA and low-risk disease.

CaP Screening
- PSA is specific to the PROSTATE, but NOT to prostate cancer.
- Causes of Increased PSA: BPH, prostatitis, prostatic ischemia/infarction, prostate biopsy/surgery, prostatic massage, acute urinary retention, urethral catheterization, cystoscopy, TRUS, strenuous exercise, perineal trauma, ejaculation, acute renal failure, coronary bypass graft, radiation therapy.

Table 20. Treatment Options for Localized Prostate Cancer

<table>
<thead>
<tr>
<th>Modality</th>
<th>Population Considered</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Watchful Waiting</td>
<td>Short life expectancy (&lt;5-10 yr); will likely only receive non-curative hormonal therapy if disease progresses</td>
<td>Disease progression</td>
</tr>
<tr>
<td>Active Surveillance (serial PSA, DRE, and biopsies)</td>
<td>Low grade disease, good F/U; is still considering more curative treatment if disease progresses</td>
<td>Disease progression; decrease in QOL associated with serial testing; risks associated with biopsies; no optimal monitoring schedule has been defined to date</td>
</tr>
<tr>
<td>Brachytherapy</td>
<td>Low volume, low PSA (&lt;10), low grade</td>
<td>ED (50%), long term effectiveness not well-established</td>
</tr>
<tr>
<td>EBRT</td>
<td>Locally advanced disease, older patients</td>
<td>Radiation proctitis (5%), ED (50%), risk of rectal cancer</td>
</tr>
<tr>
<td>RP</td>
<td>Young patients (&lt; 75 yr), high-risk disease</td>
<td>Incontinence (10%), ED (30-50%)</td>
</tr>
</tbody>
</table>

Notes: Other options include cryosurgery, HIFU, hormonal ablation.

Prognosis
- T1-T2: comparable to normal life expectancy
- T3-T4: 40-70% 10-yr survival
- N+ and/or M+: 40% 5-yr survival
- prognostic factors: tumour stage, tumour grade, PSA value, PSA doubling time

Digital Rectal Exam (DRE)
- should be included as part of initial screening
- suspicious findings: abnormal feeling, nodularity, focal lesion, discrete change in texture/fullness/symmetry

Prostate Specific Antigen (PSA)
- glycoprotein produced by epithelial cells of prostate gland
- leaks into circulation in settings of disrupted glandular architecture
- value of <4 ng/mL traditionally considered as cut-off to differentiate normal from pathologic value, but no single justifiable cutpoint
- measured serum PSA is a combination of free (15%) and bound PSA (85%)
- PSA velocity, PSA density, and free/total PSA: all intended to increase sensitivity and specificity of serum PSA values

Screening Recommendations
- conflicting evidence regarding mortality reduction with PSA-based screening and debate regarding overdiagnosis/ overtreatment
- Ontario Ministry of Health and Long-Term Care and United States Preventative Services Task Force both recommend against PSA testing as a population-wide screening tool
- serum PSA determination recommended in any man with >10 yr life-expectancy and any of the following:
  - suspicious finding on DRE (see above)
  - moderate-severe LUTS
  - investigating secondary carcinoma of unknown origin to r/o CaP as primary

Treatment
- T1/T2 (localized, low-risk)
  - if adequate life expectancy or no other significant co-morbidities, consider active surveillance vs. definitive local treatment (RP, brachytherapy, or EBRT)
  - no difference in cure rate between definitive treatment modalities
- T1/T2 (intermediate or high-risk)
  - definitive therapy over active surveillance
- T3, T4
  - EBRT + androgen deprivation therapy or RP + adjuvant EBRT
- N >0 or M >0
  - requires hormonal therapy/palliative radiotherapy for metastases; may consider combined androgen blockade
  - bilateral orchectomy – removes 90% of testosterone
  - GnRH agonists (e.g. leuprolide, goserelin)
  - estrogens [e.g. diethylstilbestrol (DES)]
  - antiandrogens (bicalutamide)
  - local irradiation of painful secondaries or half-body irradiation
  - hormone-refractory prostate cancer
  - chemotherapy: docetaxel, cabazitaxel, sipuleucel-T

NOTES:
- If suspicious finding on DRE (see above)
- chemotherapy: docetaxel, cabazitaxel, sipuleucel-T
Canadian Urological Association Guidelines (2011) re: CaP Screening
- harms and benefits of PSA testing must be explained to the patient and an informed, shared decision to test must be established
- initial screening should include both serum PSA and DRE
- all men should be offered screening at age 50 if >10 yr life-expectancy
- high-risk individuals (family hx of CaP or African ancestry) should be offered screening at age 40 if >10 yr life-expectancy
- standard has been annual screening, but q2-4 yr screening acceptable
- no strict cutpoint for when to biopsy. Decision to biopsy should be based on more than a single PSA value
*new guidelines under development, however, AUA guidelines recommend against universal routine PSA screening for CaP

Testicular Tumours

Etiology (Risk Factors)
- cryptorchidism, atrophy, sex hormones, HIV infection, infertility, family hx, past hx of testicular cancer

Epidemiology
- rare, but most common solid malignancy in young males 15-34 yr
- any solid testicular mass or acute hydrocele in young patient – must r/o malignancy
- slightly more common in right testis (corresponds with slightly higher incidence of right-sided cryptorchidism)
- 2-3% bilateral (simultaneously or successively)

Pathology
- primary:
  - 1% of all malignancies in males
  - cryptorchidism has increased risk (10-40x) of malignancy
  - 95% are germ cell tumours (all are malignant)
    - seminoma (35%) → classic, anaplastic, spermatocytic
    - NSGCT → embryonal cell carcinoma (20%), teratoma (5%), choriocarcinoma (<1%), yolk sac (<<1%), mixed cell type (40%)
  - 5% are non-germ cell tumours (usually benign) → Leydig (testosterone, precocious puberty), Sertoli (gynecomastia, decreased libido)
- secondary:
  - male >50 yr
  - usually lymphoma or metastases (e.g. lung, prostate, GI)

Clinical Features
- painless testicular enlargement (painful if intratesticular hemorrhage or infarction)
- dull, heavy ache in lower abdomen, anal area or scrotum
- associated hydrocele (10%)
- coincidental trauma (10%)
- infertility (rarely presenting complaint)
- gynecomastia due to secretory tumour effects
- supraclavicular and inguinal lymphadenopathy
- abdominal mass (retroperitoneal lymph node mets)

Methods of Spread
- local spread follows lymphatics:
  - right → medial, paracaval, anterior and lateral nodes
  - left → left lateral and anterior paraaortic nodes
  - “cross-over” metastases from right to left are fairly common, but no reports from left to right
  - hematogenous most commonly to lung, liver, bones, and kidney

Investigations
- diagnosis is established by radical inguinal orchidectomy
- tumour markers:
  - β-hCG and AFP are positive in 85% of non-seminomatous tumours
  - elevated marker levels return to normal post-operatively if no secondaries
  - β-hCG positive in 7% of seminomas, AFP never elevated with seminoma
  - testicular U/S (hypoechoic area within tunica albuginea = high suspicion of testicular cancer)
  - evidence of testicular microlithiasis is not a risk factor for testicular cancer
  - needle aspiration contraindicated

Management
- orchiectomy through inguinal ligament for all stages
- consider sperm banking
- adjuvant therapies (see Figure 13)
Table 21. 2010 TNM Classification of Testicular Carcinoma

| Tis: intratubular germ cell neoplasia | N status: same as RCC | M0: no distant mets |
| T1: limited to testis and epididymis w/o vascular/lymphatic invasion | | M1: distant mets |
| T2: limited to testis and epididymis w/ vascular/lymphatic invasion | | M1a: nonregional lymph node(s) or pulmonary mets |
| T3: invasion of the spermatic cord ± vascular/lymphatics | | M1b: distant mets other than to regional lymph nodes and lung |
| T4: invasion of the scrotum ± vascular/lymphatics | | |

RPLND ± ✓ ✓ ✓ (residual mass)
Chemotherapy ? ✓ ? ✓ ✓

Figure 13. Adjuvant management of testicular cancer post-orchiectomy
Adapted from Dr. MAS Jewett

Prognosis
- 99% cured with stage I and II disease
- 70-80% complete remission with advanced disease

Penile Tumours

Epidemiology
- rare (<1% of cancer in males in U.S.)
- most common in 6th decade

Benign
- cyst, hemangioma, nevus, papilloma

Pre-malignant
- balanitis xerotica obliterans, leukoplakia, Buschke-Lowenstein tumour (large condyloma)

Pre-invasive Cancer
- carcinoma in situ (CIS):
  - Bowen's disease → crusted, red plaques on the shaft
  - erythroplasia of Queyrat → velvet red, ulcerated plaques on the glans
  - treatment options: local excision, laser, radiation, topical 5-fluorouracil

Malignant
- risk factors:
  - chronic inflammatory disease
  - STI
  - phimosis
  - uncircumcised penis
- 2% of all urogenital cancers
- SCC (>95%), basal cell, melanoma, Paget's disease of the penis (extremely rare)
- definitive diagnosis requires full thickness biopsy of lesion
- lymphatic spread (superficial/deep inguinal nodes → iliac nodes) >> hematogenous

Treatment
- wide surgical excision with tumour-free margins (dependent on extent and area of penile involvement) ± lymphadenectomy
- consider less aggressive treatment modalities in CIS (cryotherapy, laser therapy, etc.) if available

</tbody>
</table>
TORSION OF TESTICULAR APPENDIX
- twisting of testicular/epididymal vestigial appendix

Signs and Symptoms
- clinically similar to testicular torsion, but vertical lie and cremaster reflex preserved
  - “blue dot sign”:
    - blue infarcted appendage seen through scrotal skin (can usually be palpated as small, tender lump)

Treatment
- analgesia – most will subside over 5-7 d
- surgical exploration and excision if refractory pain

HEMATOCELE
- trauma with bleed into tunica vaginalis
- U/S helpful to exclude fracture of testis which requires surgical repair

Treatment
- ice packs, analgesics, surgical repair

Penile Complaints

Peyronie’s Disease

Definition
- benign curvature of penile shaft secondary to fibrous thickening of tunica albuginea
  - most commonly on dorsal surface resulting in upward curvature of erect penis

Etiology
- exact etiology unknown
- trauma/repeated microtrauma → inflammation → fibrosis
- familial predisposition
- associated with DM, vascular disease, autoimmunity, Dupuytren’s contracture, erectile dysfunction
- unclear role of vitamin E deficiency, β-blockade, elevated serotonin

Clinical Features
- penile curvature and/or pain with erection
- penile shortening and poor erection distal to plaque

Treatment
- limited evidence, depends on pain and interference with intercourse

Table 24. Treatment of Peyronie’s Disease

Priapism

Definition
- prolonged erection lasting >4 h in the absence of sexual excitement/desire
- tumescence (swelling) of corpora cavernosa with flaccid glans penis (no corpora spongiosum involvement)

Classification
- low-flow/ischemic (most common):
  - reduced/absent cavernosal blood flow → hypoxia, acidosis → ischemia
- high-flow/non-ischemic:
  - unregulated arterial flow with normal tissue oxygenation

Suspect a Retroperitoneal Mass/Process in a Patient with a Varicocele if:
- Acute onset
- Right sided (isolated)
- Palpable abdominal mass
- Doesn’t reduce while supine

Indications for Treatment of Varicocele
- Impaired sperm quality or quantity
- Pain or dull ache affecting QOL
- Affected testis fails to grow in adolescents
- Cosmetic indications (especially in adolescents)
Etiology

- primary: up to 50% idiopathic
- secondary:
  - thromboembolic: e.g. sickle cell, thalassemia, total parenteral nutrition, dialysis, leukemia, solid tumours
  - neurogenic: spinal cord injury, autonomic neuropathy
  - traumatic: cavernosal artery laceration, arterio-venous fistula
  - medication: intracavernosal vasoactive drug injection (e.g. triple mix), α-blockers, anticoagulants, antidepressants, antipsychotics, PDE-5 inhibitors
  - recreational drugs: cocaine, marijuana, heavy alcohol intake

Treatment

- treat reversible causes
- high-flow often self-limited, but arterial embolization may be considered
- low-flow:
  1. urgent decompression via needle aspiration
  2. phenylephrine injection into the corpora cavernosa q3-5min (in monitored setting)
  3. shunt creation between cavernosum and spongiosum if no response within 1 h

Complications

- ED due to corporal fibrosis if treatment delayed
  - 90% risk if >24 h

Paraphimosis

Definition

- foreskin caught behind glans leading to edema → inability to reduce foreskin

Treatment

- squeeze edema out of the glans with manual pressure (analgesia required)
- pull on foreskin with fingers while pushing on glans with thumbs
- if fails, perform dorsal slit or circumcision
- elective circumcision for definitive treatment (paraphimosis tends to recur)

Complications

- infection, glans ischemia, gangrene

Phimosis

Definition

- inability to retract foreskin over glans penis
- may be caused by balanitis (infection of glans), often due to poor hygiene or congenital

Treatment

- proper hygiene, topical corticosteroids, dorsal slit, circumcision

Complications

- balanoposthitis (inflammation of prepuce), paraphimosis, penile cancer

Erectile Dysfunction (ED)

Definition

- consistent (>3 mo duration) or recurrent inability to obtain or maintain an adequate erection for satisfactory sexual performance

Physiology

- erection involves the coordination of psychologic, neurologic, hemodynamic, mechanical, and endocrine components
- nerves: sympathetic (T11-L2), parasympathetic (S2-4), somatic [dorsal penile/pudendal nerves (S2-4)]
- erection ("POINT"):
  - parasympathetics → release of nitric oxide (NO) → increased cGMP levels within corpora cavernosa leading to:
    1. arteriolar dilation
    2. sinusoidal smooth muscle relaxation → increased arterial inflow and compression of penile venous drainage (decreased venous outflow)
• emission (“SHOOT”):
  ▪ sensory afferents from glans
  ▪ secretions from prostate, seminal vesicles, and ejaculatory ducts enter prostatic urethra (sympathetics)
• ejaculation (“SHOOT”)
  ▪ bladder neck closure (sympathetic)
  ▪ spasmotic contraction of bulbo-cavernosus and pelvic floor musculature (somatic)
• detumescence:
  ▪ sympathetic nerves, norepinephrine, endothelin-1 → arteriolar and sinusoidal constriction
  → penile flaccidity

Classification

Etiology (“IMPOTENCE”)  
• Iatrogenic: pelvic surgery, pelvic radiation  
• Mechanical: Peyronie’s, post-priapism  
• Psychological: depression, stress, anxiety, PTSD, widower syndrome  
• Occlusive vascular: arterial HTN, DM, smoking, hyperlipidemia, PVD, venous (impaired veno-occlusion)  
• Trauma: penile/pelvic, bicycling  
• Extra factors: renal failure, cirrhosis, COPD, sleep apnea, malnutrition  
• Neurogenic: CNS (e.g. Parkinson’s, MS, spinal cord injury, Guillain–Barré, spina bifida, stroke), PNS (e.g. DM, peripheral neuropathy)  
• Chemical: antihypertensives, sedatives, antidepressants, antipsychotics, anxiolytics, anticholinergics, antihistamines, anti-androgens (including 5-α reductase inhibitors), statins, GnRH agonists, illicit drugs  
• Endocrine: DM, hypogonadism, hyperprolactinemia, hypo/hyperthyroid

Diagnosis

• complete hx (include sexual, medical, and psychosocial aspects)  
• self-administered questionnaires (e.g. International Index of Erectile Function, Sexual Health Inventory for Men Questionnaire, ED Intensity Scale, ED Impact Scale)  
• focused P/E, including vascular and neurologic examinations, secondary sexual characteristics  
• lab investigations, dependent on clinical picture  
  ▪ risk factor evaluation: fasting blood glucose or HbA1c, cholesterol profile  
  ▪ optional: TSH, CBC, U/A, testosterone (free and total), prolactin, LH  
• specialized testing including nocturnal penile tumescence monitoring and evaluation of penile vasculature is usually unnecessary

Treatment

• can often be managed by family doctor, see sidebar for when to refer  
• must fully inform patient/partner of options, benefits and complications  
• non-invasive:  
  ▪ lifestyle changes (alcohol, smoking), psychological (sexual counseling and education)  
  ▪ change precipitating medications  
  ▪ treat underlying causes (diabetes, CVD, HTN, endocrinopathies)  
• minimally invasive:  
  ▪ oral medication (see Common Medications, U43)  
  ▪ sildenafil, tadalafil, vardenafil: inhibits PDE-5 to increase intracavernosal cyclic GMP levels  
    ▪ all three have similar effectiveness, but tadalafil has certain advantages: earlier onset, longer half-life, no cyanopsia, can be taken on empty or full stomach (others better on empty stomach)  
  ▪ vacuum devices: draw blood into penis via negative pressure, then put ring at base of penis once erect  
  ▪ MUSE: male urethral suppository for erection – vasoactive substance (PGE1) capsule inserted into urethra

Testosterone deficiency is an uncommon cause of ED.

When to Consider Referral

FAT PEN
  Failed medical therapy  
  penile Anatomic abnormality  
  pelvic/perineal Trauma  
  Psychogenic cause  
  Endocrinopathy  
  vascular/Neurologic assessment

PDE-5 inhibitors are contraindicated in patients on nitrates/nitroglycerin due to severe hypotension.
**Premature Ejaculation**

**Definition**
- occurrence of ejaculation prior to when one or both partners desire it, either before or soon after penetration
- often thought to be due to psychological factors
- primary premature ejaculation
  - never experienced sexual activity without the presence of premature ejaculation
- secondary premature ejaculation
  - the individual once had acceptable ejaculatory control, but now experiences premature ejaculation, not associated with a general medical condition

**Epidemiology**
- 3-30% prevalence (self-reporting is consistently higher than clinical prevalence)
- most common sexual dysfunction reported in men 18-30 yr, associated with secondary impotence in men 45-65 yr

**Investigations**
- indicated by hx and P/E
- testosterone levels if in conjunction with impotence

**Treatment**
- must r/o and treat any associated general medical conditions (e.g. fear of angina)
- referral to psychiatry, couples counseling or sex therapy
- SSRIs or clomipramine, either daily or on-demand dosing
- topical lidocaine and/or prilocaine

---

**Trauma**

- see Emergency Medicine, ER14

---

**Renal Trauma**

**Classification According to Severity**
- minor:
  - contusions and superficial lacerations/hematomas: 90% of all blunt traumas, surgical exploration seldom necessary
- major:
  - laceration that extends into medulla and collecting system, major renal vascular injury, shattered kidney

**Etiology**
- 80% blunt (MVC, assaults, falls) vs. 20% penetrating (stab wounds and gunshots)

**Clinical Features**
- mechanism of injury raises suspicion
- can be hemodynamically unstable secondary to renal vascular injury and/or other sustained injuries: ABCs
- upper abdominal tenderness, flank tenderness, flank contusions, lower rib/vertebral transverse process fracture

**Investigations**
- U/A:
  - hematuria: requires workup but degree does not correlate with the severity of injury
- imaging:
  - CT (contrast, triphasic) if patient stable: look for renal laceration, extravasation of contrast, retroperitoneal hematoma, and associated intra-abdominal organ injury
Staging (does not necessarily correlate well with clinical status)
- I: contusion/hematoma
- II: <1 cm laceration without urinary extravasation
- III: >1 cm laceration without urinary extravasation
- IV: urinary extravasation
- V: shattered kidney or avulsion of pedicle

Treatment
- microscopic hematuria + isolated well-staged minor injuries → no hospitalization
- gross hematuria + contusion/minor lacerations → hospitalize, bedrest, repeat CT if bleeding persists
- surgical intervention/minimally invasive angiography and embolization:
  - absolute indications:
    - hemorrhage and hemodynamic instability
  - relative indications:
    - non-viable tissue and major laceration
    - urinary extravasation
    - vascular injury
    - expanding or pulsating peri-renal mass
    - laparotomy for associated injury
- F/U with U/S or CT before D/C, and at 6 wk

Complications
- HTN in 5% of renal trauma

Bladder Trauma

Classification
- contusions: no urinary extravasation, damage to mucosa or muscularis
- intraperitoneal ruptures: often involve the bladder dome
- extraperitoneal ruptures: involve anterior or lateral bladder wall in full bladder

Etiology
- blunt (MVC, falls, and crush injury) vs. penetrating trauma to lower abdomen, pelvis, or perineum
- blunt trauma is associated with pelvic fracture in 97% of cases

Clinical Features
- abdominal tenderness, distention, peritonitis, and inability to void
- can be hemodynamically unstable secondary to pelvic fracture, other sustained injuries: ABCs
- suprapubic pain

Investigations
- U/A: gross hematuria in 90%
- imaging (including CT cystogram and post-drainage films for extravasation)

Treatment
- penetrating trauma → surgical exploration
- contusion → urethral catheter until hematuria completely resolves
- extraperitoneal bladder perforations → typically non-operative with foley insertion, and follow with cystograms
  - surgery if: infected urine, rectal/vaginal perforation, bony spike into bladder, laparotomy for concurrent injury, bladder neck involvement, persistent urine leak and failed conservative management
- intraperitoneal rupture usually requires surgical repair and suprapubic catheterization

Complications
- complications of bladder injury itself are rare
- mortality is around 20%, and is usually due to associated injuries rather than bladder rupture
Urethral Injuries

Etiology
- posterior urethra:
  - common site of injury is junction of membranous and prostatic urethra due to blunt trauma, MVCs, pelvic fracture
  - shearing force on fixed membranous and mobile prostatic urethra
- anterior urethra:
  - straddle injury can crush bulbar urethra against pubic rami
- other causes:
  - iatrogenic (instrumentation, prosthesis insertion), penile fracture, masturbation with urethral manipulation
- always look for associated bladder rupture

Clinical Features
- blood at urethral meatus
- high-riding prostate on DRE
- swelling and butterfly perineal hematoma
- penile and/or scrotal hematoma
- sensation of voiding without U/O
- distended bladder

Investigations
- must perform RUG or cystoscopy prior to catheterization

Treatment
- simple contusions:
  - no treatment
- partial urethral disruption:
  - very gentle attempt at catheterization by urologist
  - with no resistance to catheterization → Foley x 2-3 wk
  - with resistance to catheterization → suprapubic cystostomy or urethral catheter alignment in OR
- periodic flow rates/urethrograms to evaluate for stricture formation
- complete disruption:
  - immediate repair if patient stable, delayed repair if unstable (suprapubic tube in interim)

Complications
- stricture

Infertility

Definition
- failure to conceive after one year of unprotected, properly timed intercourse
- incidence:
  - 15% of all couples
  - ~ 35-40% female, 20% male, 25-30% combined problem

Female Factors
- see Gynecology, GY22

Male Reproduction
- hypothalamic-pituitary-testicular axis (HPTA):
  - pulsatile GnRH from hypothalamus acts on anterior pituitary stimulating release of LH and FSH
  - LH acts on Leydig (interstitial) cells → testosterone synthesis and secretion
  - FSH acts on Sertoli cells → structural and metabolic support to developing spermatogenic cells
  - FSH and testosterone support germ cells (responsible for spermatogenesis)
  - sperm route: epididymis → vas deferens → ejaculatory ducts → prostatic urethra
Etiology
- idiopathic (40-50% infertile males)
- testicular
  - varicocele (35-40% infertile males)
  - tumour
    - congenital (Klinefelter’s triad: small, firm testes, gynecomastia, and azoospermia)
    - post-infectious (epididymo-orchitis, STIs, mumps)
    - uncorrected torsion
    - cryptorchidism (<5% of cases)
- obstructive
  - iatrogenic (surgery: see below)
  - infectious (gonorrhea, chlamydia)
  - trauma
  - congenital (absence of vas deferens, CF)
  - bilateral ejaculatory duct obstruction, epididymal obstructions
  - Kartagener’s syndrome (autosomal recessive disorder causing defect in action of cilia)
- endocrine (see Endocrinology, E47)
  - HPTA (2-3%) e.g. Kallmann’s syndrome (congenital hypothalamic hypogonadism), excess prolactin, excess androgens, excess estrogens
- other
  - retrograde ejaculation secondary to surgery
  - medications (see below)
    - drugs: marijuana, cocaine, tobacco, alcohol
    - increased testicular temperature (sauna, hot baths, tight pants or underwear)
  - chronic disease: e.g. liver, renal
  - unexplained infertility

History
- age of both partners
- medical: past illness, DM, trauma, CF, genetic syndromes, STIs
- surgical: vasectomy, herniorrhaphy orchidopexy, cryptorchidism, prostate surgery
- fertility: pubertal onset, previous pregnancies, duration of infertility, treatments
- sexual: libido, erection/ejaculation, timing, frequency
- family hx
- medications: cytotoxic agents, GnRH agonists, anabolic steroids, nitrofurantoin, cimetidine, sulfasalazine, spironolactone, α-blockers
- social hx: alcohol, tobacco, cocaine
- occupational exposures: radiation, heavy metals

Physical Exam
- general appearance: sexual development, gynecomastia, obesity
- scrotal exam: size, consistency and nodularity of testicles; palpation of cord; DRE; Valsalva for varicocele

Investigations
- semen analysis (SA) at least 2 properly obtained specimens over several weeks
- hormonal evaluation:
  - indicated with abnormal SA (rare to be abnormal with normal SA)
  - testosterone and FSH
  - serum LH and prolactin are measured if testosterone or FSH are abnormal
- genetic evaluation:
  - chromosomal studies (Klinefelter’s syndrome – XXY)
  - genetic studies (Y-chromosome microdeletion, CF gene mutation)
  - immunologic studies (antisperm antibodies in ejaculate and blood)
  - testicular biopsy
  - scrotal U/S (varicocele, testicular size)
  - vasography (assess patency of vas deferens)

Treatment
- assessment of partner
- lifestyle
  - regular exercise, healthy diet
  - eliminate alcohol, tobacco and illicit drugs
- medical
  - endocrine therapy (see Endocrinology, E48)
  - treat retrograde ejaculation
  - discontinue anti-sympathomimetic agents, may start α-adrenergic stimulation (phenylpropanolamine, pseudoephedrine, orephedrine)
  - treat underlying infections
• surgical
  ▪ varicocelectomy (if indicated)
  ▪ vasovasostomy (vasectomy reversal)
  ▪ epididymovasostomy
  ▪ transurethral resection of blocked ejaculatory ducts
• assisted reproductive technologies (ART):
  ▪ refer to infertility specialist
  ▪ sperm washing + intrauterine insemination (IUI)
  ▪ in vitro fertilization (IVF)
  ▪ intracytoplasmic sperm injection (ICSI) after CF screening of patient and partner in patients
    with congenital bilateral absence of vas deferens

Figure 15. Infertility workup

**Pediatric Urology**

**Congenital Abnormalities**

• not uncommon; 1/200 have congenital abnormalities of the GU tract
• six common presentations of congenital urological abnormalities:

1. **ANTENATAL HYDRONEPHROSIS**

Epidemiology
• 1-5% fetal U/S, detectable as early as first trimester
• most common urological consultation in perinatal period and one of most common U/S
  abnormalities of pregnancy

Differential Diagnosis
• UPJ or UVJ obstruction
• multi-cystic dysplastic kidney
• VUR
• PUVs (only in boys)
• duplication anomalies
• ureterocele
• ectopic ureter

Treatment
• antenatal in utero intervention rarely indicated unless evidence of PUVs with oligohydramnios

2. **POSTERIOR URETHRAL VALVES (PUV)**

Epidemiology
• the most common congenital obstructive urethral lesion in male infants
Pathophysiology
- abnormal mucosal folds at the distal prostatic urethra causing varying degrees of obstruction

Clinical Presentation
- dependent on age:
  - antenatal: bilateral hydrourephrosis, distended bladder, oligohydramnios
  - neonatal (recognized at birth): palpable abdominal mass (distended bladder, hydrourephrosis), ascites (transudation of retroperitoneal urine), respiratory distress (pulmonary hypoplasia from oligohydramnios), weak urinary stream
  - neonatal (not recognized at birth): within weeks present with urosepsis, dehydration, electrolyte abnormalities, failure to thrive
  - toddlers: UTIs or voiding dysfunction
  - school-aged boys: voiding dysfunction → urinary incontinence
- associated findings include renal dysplasia and secondary VUR

Investigations
- most commonly recognized on prenatal U/S → bilateral hydrourephrosis, thickened bladder, dilated posterior urethra (“keyhole sign”), oligohydramnios in a male fetus
- VCUG → dilated and elongated posterior urethra, trabeculated bladder, VUR

Treatment
- immediate catheterization to relieve obstruction, followed by cystoscopic resection of PUV when baby is stable
- if resection of PUV is not possible, vesicostomy is indicated

3. URETEROPELVIC JUNCTION (UPJ) OBSTRUCTION

Etiology
- unclear: adynamic ureteral segment, stenosis, strictures, extrinsic compression, stenosis, strictures, aberrant blood vessels
- can be secondary to tumour, stone, etc.

Epidemiology
- the most common congenital defect of the ureter
- M:F = 2:1
- up to 40% bilateral, which may be associated with worse prognosis

Clinical Presentation
- symptoms depend on severity and age at diagnosis (mostly asymptomatic finding on antenatal U/S)
  - infants: abdominal mass, urinary infection
  - children: pain, vomiting, failure to thrive
- some cases are diagnosed after puberty and into adulthood
  - in adolescents and adults, the symptoms may be triggered by episodes of increased diuresis, such as following alcohol ingestion (Dietl’s crisis)

Investigations
- antenatal U/S most common, Doppler U/S (rare), IVP (rare), and renal scan ± furosemide

Treatment
- surgical correction (pyeloplasty), consider nephrectomy if <15% differential renal function

4. VESICOURETERAL REFUX (VUR)

Definition
- retrograde passage of urine from the bladder, through the ureterovesicular junction (UVJ), into the ureter

Classification
- primary reflux: incompetent or inadequate closure of UVJ
  - lateral ureteral insertion, short submucosal segment
- secondary reflux: abnormally high intravesical pressure resulting in failure of UVJ closure
  - often associated with anatomic (PUV) or functional (neurogenic) bladder obstruction

Epidemiology
- estimated ~1% of newborns, but not well known
- incidence and clinical relevance higher in children with febrile UTIs and prenatal hydrourephrosis
- risk factors: race (white > black), female gender, age (<2 yr), genetic predisposition
Investigations
- focused hx, particularly of voiding dysfunction (frequency, urgency, diurnal enuresis, constipation, encopresis)
  - also screen for signs of infection (UTI, pyelonephritis, urosepsis) and renal failure (uremia, HTN)
- initial evaluation of renal status, growth parameters, and blood pressure is warranted in any child with VUR due to high incidence of renal scarring
  - height, weight, blood pressure
  - Cr
  - U/A, C&S
  - renal U/S
  - DMSA renal scan if at high risk (greater sensitivity than U/S but entails radiation exposure)
- family screening is controversial

Treatment
- spontaneous resolution in 60% of primary reflux
  - in lower grades (I-III), goal is to prevent infection or renal damage via medical treatment and monitoring
- medical treatment: long-term ABx prophylaxis at half the treatment dose for half the treatment time (TMP/SMX, trimethoprim, amoxicillin, or nitrofurantoin)
- surgical treatment: ureteral reimplantation ± ureteroplasty, or subureteral injection with bulking agents (Deflux® or Macroplastique®)
  - indications include failure of medical management, renal scarring (e.g. renal insufficiency, HTN), breakthrough UTIs, persistent high grade (IV or V) reflux

5. HYPOSPADIAS

Definition
- a condition in which the urethral meatus opens on the ventral side of the penis, proximal to the normal location in the glans penis
- depending on severity, may result in difficulty directing urinary stream or infertility

Epidemiology
- very common; 1/300 live male births
- white >> black
- may be associated with ventral penile curvature, disorders of sexual differentiation, undescended testicles or inguinal hernia

Treatment
- early surgical correction; optimal repair before 2 yr
- neonatal circumcision should be deferred because the foreskin may be utilized in the correction

6. EPISPADIAS-EXTROPHY COMPLEX

Definition
- a spectrum of defects depending on the timing of the rupture of the cloacal membrane
  - bladder extrophy: congenital absence of a portion of lower abdominal and anterior bladder wall, with exposure of the bladder lumen
  - cloacal extrophy:
    - exposed bladder and bowel with imperforate anus
    - associated with spina bifida in >50%
  - epispadias (least severe)
    - urethra opens on dorsal aspect of the penis

Etiology
- represents failure of closure of the cloacal membrane, resulting in the bladder and urethra opening directly through the abdominal wall

Epidemiology
- rare: incidence 1/30,000, 3:1 male to female predominance
- high morbidity → incontinence, infertility, reflux

Treatment
- surgical correction at birth
- later corrections for incontinence, VUR, and bladder capacity may be needed
Nephroblastoma (Wilms’ Tumour)

Etiology
• arises from abnormal proliferation of metanephric blastema

Epidemiology
• 5% of all childhood cancers, 5% bilateral
• most common primary malignant renal tumour of childhood
• average age of incidence is 3 yr

Clinical Features
• abdominal mass: large, firm, unilateral (80%)
• HTN (25%)
• flank tenderness
• microscopic hematuria
• nausea/vomiting

Treatment
• always investigate contralateral kidney
• unilateral disease: radical nephrectomy ± radiation ± chemotherapy
• bilateral disease: nephron-sparing surgery following neoadjuvant chemotherapy

Prognosis
• 5-yr survival 80%

Cryptorchidism/Ectopic Testes

Definition
• abnormal location of testes somewhere along the normal path of descent (external inguinal ring > inguinal canal > abdominal)
• ectopic testis (testis found outside its normal path of descent) is most commonly located within a superficial pouch between the external oblique fascia and Scarpas fascia (Denis Browne pouch)
• differential diagnosis:
  ▪ retractile testes
  ▪ atrophic testes
  ▪ disorders of sexual differentiation (bilateral impalpable gonads)

Epidemiology
• 2.7% of full term newborns
• 0.7%-0.8% at 1 yr old

Treatment
• orchiopexy
• hormonal therapy not proven to be of benefit over standard surgical treatment

Prognosis
• reduction in fertility
  ▪ untreated bilateral cryptorchidism: ~100% infertility
  ▪ paternity rates: 53%, 90%, and 93% in formerly bilateral cryptorchid, formerly unilateral cryptorchid, and normal men, respectively
  ▪ increased malignancy risk
    ▪ intraabdominal > inguinal
  ▪ surgical correction facilitates testicular monitoring and may reduce malignancy risk
  ▪ increased risk of testicular torsion (reduced by surgical correction)

Disorders of Sexual Differentiation (DSD)

Definition
• formerly known as intersex disorders
• abnormal genitalia for chromosomal sex due to the undermasculinization of males or the virilization of females
• considered a social emergency

Classification
1. 46 XY DSD
  ▪ defect in testicular synthesis of androgens
  ▪ androgen resistance in target tissues
  ▪ palpable gonad
2. 46 XX DSD
   • most due to CAH (21-hydroxylase deficiency most common enzymatic defect) → shunt in steroid biosynthetic pathway leading to excess androgens
   • undiagnosed and untreated CAH can be associated with life-threatening electrolyte abnormalities in the newborn (salt-wasting CAH)
3. ovotesticular DSD
4. mixed gonadal dysgenesis (46 XY/45 XO most common karyotype)
   • presence of Y chromosome → partial testis determination to varying degrees

Diagnosis
• thorough family hx noting any consanguinity
• maternal hx, especially medication/drug use during pregnancy (maternal hyperandrogenemia)
• P/E: palpable gonad (= chromosomal male), hyperpigmentation, evidence of dehydration, HTN, stretched phallus length, position of urethral meatus
• laboratory tests:
  • plasma 17-OH-progesterone (after 36 h of life) → increased in 21-hydroxylase deficiency (CAH)
  • plasma 11-deoxycortisol → increased in 11-β-hydroxylase deficiency
  • basal adrenal steroid levels
  • serum testosterone and DHT pre- and post-hCG stimulation (2,000 IU/d for 4 d)
  • serum electrolytes
  • chromosomal evaluation including sex karyotype
• U/S of adrenals, gonads, uterus, and fallopian tubes
• P/E: palpable gonad (= chromosomal male), hyperpigmentation, evidence of dehydration, HTN, maternal hx, especially medication/drug use during pregnancy (maternal hyperandrogenemia)
• thorough family hx noting any consanguinity

Treatment
• steroid supplementation as indicated (e.g. CAH)
• sex assignment after extensive family consultation
  • must consider capacity for sexually functioning genitalia in adulthood, fertility potential, and psychological impact
• reconstruction of external genitalia between 6 and 12 mo
• long-term psychological guidance and support for both patient and family

Circumcision

Definition
• removal of some or all of the foreskin from the penis

Epidemiology
• 30% worldwide
• frequency varies depending on geographic location, religious affiliation, socioeconomic classification

Medical Indications
• phimosis and recurrent paraphimosis
• recurrent UTIs (particularly in infants and in association with other urinary abnormalities)
• balanitis xerotica obliterans or other chronic inflammatory conditions

Contraindications
• unstable or sick infant
• congenital genital abnormalities (hypospadias)
• family hx of bleeding disorders warrants laboratory investigation prior to circumcision

Complications
• bleeding
• infection
• penile entrapment, skin bridges
• fistula
• glans injury
• penile sensation deficits

Enuresis
• see Pediatrics, P9
**Bladder Catheterization**

- catheter size measured by the French (Fr) scale – circumference in mm
- each 1 mm increase in diameter = approximately 3 Fr increase (standard size 16-18 Fr)
- should be removed as soon as possible

**Continuous Catheterization**

- indications:
  - accurate monitoring of U/O
  - relief of urinary retention due to medication, neurogenic bladder, or intravesical obstruction
  - temporary therapy for urinary incontinence
  - perineal wounds
  - clot prevention (24-28 Fr) for CBI
  - post-operative

**Alternatives to Continuous Catheterization**

- intermittent catheterization:
  - PVR measurement
  - to obtain sterile diagnostic specimens for U/A, urine C&S
  - management of neurogenic bladder or chronic urinary retention
- condom catheter
- suprapubic catheter

**Causes of Difficult Catheterizations and Treatment**

- patient discomfort → use sufficient lubrication (± xylocaine)
- collapsing catheter → lubrication as above ± firmer catheter (silastic catheter)
- meatal/urethral stricture → dilate with progressively larger catheters/balloon catheter
- BPH → use coudé catheter as angled tip can help navigate around prostate
- urethral disruption/obstruction → filiform and followers or suprapubic catheterization
- anxious patient → anxiolytic medication

**Complications of Catheterization**

- infection: UTI
- meatal/urethral trauma

**Contraindications**

- urethral trauma: blood at the meatus of the urethra, scrotal hematoma, pelvic fracture, and/or high riding prostate

**Cystoscopy**

**Objective**

- endoscopic inspection of the lower urinary tract (urethra, prostate, bladder, and ureteral orifices), samples for cytology
- scopes can be flexible or rigid

**Indications**

- gross hematuria
- LUTS (storage or voiding)
- urethral and bladder neck strictures
- bladder stones
- bladder tumour surveillance
- evaluation of upper tracts with retrograde pyelography (ureteric stents, catheters)

**Complications**

- during procedure
  - bleeding
  - anesthetic-related
  - perforation (rare)
- post-procedure (short-term)
  - infections, e.g. epididymo-orchitis (rare)
  - urinary retention
- post-procedure (long-term)
  - stricture
Radical Prostatectomy (RP)

Objective
- the removal of the entire prostate and prostatic capsule via a lower midline abdominal incision, laparoscopically or robotically
  - internal iliac and obturator vessel lymph nodes may also be dissected and sent for pathology (dependent on risk: clinical stage, grade, PSA)
  - seminal vesicle vessels are also ligated or removed

Indications
- treatment for localized prostate cancer

Complications
- immediate (intraoperative):
  - blood loss
  - rectal injury
  - ureteral injury (extremely rare)
- perioperative:
  - lymphocele formation
- late:
  - moderate to severe urinary incontinence (3-10%)
  - mild urinary incontinence (20%)
  - ED (~50%, depending on whether one, both, or neither of the neurovascular bundles are involved in extracapsular extension of tumour)

Transurethral Resection of the Prostate (TURP)

Objective
- to partially resect the periurethral portion of the prostate (transition zone) to decrease symptoms of urinary tract obstruction
- accomplished via a transurethral (cystoscopic) approach using an electrocautery loop, irrigation (glycine), and illumination

Indications
- obstructive uropathy (large bladder diverticula, renal insufficiency)
- refractory urinary retention
- recurrent UTIs
- recurrent gross hematuria
- bladder stones
- intolerance/failure of medical therapy

Complications
- acute:
  - infra- or extraperitoneal rupture of the bladder
  - rectal perforation
  - incontinence
  - incision of the ureteral orifice (with subsequent reflux or ureteral stricture)
  - hemorrhage
  - epididymitis
  - sepsis
  - transurethral resection syndrome (also called “post-TURP syndrome”)
    - caused by absorption of a large volume of the hypotonic irrigation solution used, usually through perforated venous sinuses, leading to a hypervolemic hyponatremic state
    - characterized by dilutional hyponatremia, confusion, nausea, vomiting, HTN, bradycardia, visual disturbances, CHF, and pulmonary edema
    - treat with diuresis and (if severe) hypertonic saline administration
- chronic:
  - retrograde ejaculation (>75%)
  - ED (5-10% risk increases with increasing use of cautery)
  - incontinence (<1%)
  - urethral stricture
  - bladder neck contracture

Study: A systematic review to compare perioperative outcomes, positive surgical margin (PSM) rates, and functional outcomes in retropubic radical prostatectomy (RRP), laparoscopic RP (LRP) and robot-assisted radical prostatectomy (RARP).

Methods: Medline database was searched. Weighted means (based on number of participants in each study) were calculated for all outcomes.

Results: 58 articles were reviewed. LRP and RARP were associated with better perioperative outcomes compared to RRP. RRP, LRP and RARP had similar post-operative complication rates ranging from 10.3-10.98%. RARP had a lower overall PSM rate than LRP and RRP. RARP had the highest continence rate and mean potency rates.

Conclusion: In high-volume centers, RRP, LRP and RARP are safe options for treating patients with localized prostate cancer. LRP and RARP are associated with better perioperative outcomes and RARP showed lower PSM rates, higher potency and continence compared to RRP and LRP.
Extracorporeal Shock Wave Lithotripsy (ESWL)

Objective
• to treat renal and ureteral calculi (proximal, middle or distal) which cannot pass through the urinary tract naturally
• shockwaves are generated and focused onto stone → fragmentation, allowing stone fragments to pass spontaneously and less painfully

Indications
• potential first-line therapy for renal and ureteral calculi <2.5 cm
• individuals with calculi in solitary kidney
• individuals with HTN, DM or renal insufficiency
*patient preference and wait-times play a large role in stone management

Contraindications
• acute UTI or urosepsis
• bleeding disorder or coagulopathy
• pregnancy
• obstruction distal to stone

Complications
• bacteriuria
• bacteremia
• post-procedure hematuria
• ureteric obstruction (by stone fragments)
• peri-nephric hematoma

Common Medications

Table 26. Erectile Dysfunction Medications

<table>
<thead>
<tr>
<th>Drug</th>

<td>Anticholinergic</td>
<td>Muscarinic receptor antagonist Selective for bladder</td>
<td>Urge incontinence + urgency + frequency</td>
<td>As above</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Increases bladder volume</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Decreases detrusor pressure</td>
<td></td>
<td></td>
</tr>
<tr>
<td>imipramine</td>
<td>Tricyclic antidepressant</td>
<td>Sympathomimetic effects: urinary sphincter contraction Anticholinergic effects: detrusor relaxation</td>
<td>Stress and urge incontinence</td>
<td>As above Weight gain Orthostatic hypotension Prolonged PR interval</td>
</tr>
</tbody>
</table>

Note: All anti-cholinergics are equally effective and long-acting formulations are better tolerated. Newer muscarinic M3 receptor specific agents (solfenacin, darifenacin) are equally efficacious as older drugs; however, RCTs based on head-to-head comparison to long acting formulations are lacking.
